# ENGLISH MECHANIC

AND

# WORLD OF SCIENCE.

WITH WHICH ARE INCORPORATED

"THE MECHANIC," "SCIENTIFIC OPINION," AND "THE BRITISH & FOREIGN MECHANIC."

ILLUSTRATED WITH NUMEROUS PRACTICAL ENGRAVINGS.

## VOLUME XLI.

PUBLISHED (FOR THE PROPRIETOR) BY E. J. KIBBLEWHITE,
AT THE
Office: 332, STRAND, LONDON, W.C.
SOLD BY ALL BOOKSELLERS AND NEWSAGENTS IN THE KINGDOM.

1885.

Printed by BRADLEY and Company,
12, 13, and 14, Fetter Lane, London, E.C.

[*Supplement to the ENGLISH MECHANIC, September 18, 1885.*]

# INDEX TO VOL. XLI. ENGLISH MECHANIC.

**ABERRATION**, spherical, 353
Acceleration of trains, brakes, &c., 84
Accident : at King's Cross, 432, 457, 476
  at Manchester, 91
  at St. Paul's-road Junction, 59
  Binegar, 542
  Penistone, 500, 521
  Swadlincote, 566
Accumulator : electric, 152, 394
  Gimé's, 475
Acetic acid from wood, 361
Achromatic telescopes, on the colour correction of, 316, 470
Achromatism, 282
Acid : acetic, from wood, 361
  engraving with, 40
Acids, filtering, 111, 133, 153, 197
Actuarial, 485
Adjustment, micro., fine, 238, 351
Æolian harp, the, 163
Aerial navigation, 414
Aëronautics, 532, 542
Affinity, chemical, 89
Africa, exploration of, 427
Afterglow, 284
Age, changes incidental to old, 253
Agglomerate battery, 332, 550, 570
Air : and fuel, 484
  compressed, physiological effects of, 392
  cubic feet of per minute, 178, 199
  cushions, mending leaky, 306
Air-pressure at high temperatures, 265
Air-tight packages, 167
Alarm, new fire, 495, 522
Alarum clocks for experimenters and others, 129, 168
Albo-carbon, 135
Alcohol, preparation of absolute, 146
Aldebaran : occultation of, 8, 55, 428
  — daylight, 451, 474, 497, 518, 539, 562
  occultations of, future, 57
Ale, ginger, 480
Algebraical problems, 309, 330, 393, 395, 417, 437, 440, 572
Alizarine oil, 112
Alkaloids as disease producers, 585
Alloy for watch bearings, 265
Almanac, the Nautical, 427
Altazimuth motion, equatorial from, 473
Altitudes, corrections for equal, 211
Alumina, flux for, 308
Aluminium : 418, 438, 458, 481, 542, 567
  can it be extracted cheaply? 501, 520
  manufacture of, 519
Amalgamating zinc, 67, 152
Amateur : lens making, 424, 498
  microscope construction, 127
  modeller, 5.6
  photographers, dodges for, 28
  preparation of highly-sensitive gelatine emulsion, 163
  workshop, 46, 160, 250, 338, 402, 490
Amateurs : electrical instrument making for, 511, 557
  gas bags, 87
  locomotive, new, 58
  photography for, 164
American : organ, 15, 37, 64, 85, 288
  — pedal bass attachment for, 567
  — reeds, 85
  — separate pedal organ for, 171, 193
  trains, speed of, 500
Ammeter, variable resistance with, 565
Ammonia, new developer containing sulphite of, 98
Amphipleura pellucida, 35
Analysis : anhydrous, 14, 33
  commercial organic, 383
  of asbestos, 370
  simple exercises in technical, 2, 138, 204, 382
  soap, 460
  water, 531, 484
Ancient lights, 547
Anemones, sea, 88
Angles, star discs and visible, 233
Anhydrous analysis, 14, 33
Annealed castings, 193
Aperture : 100 to the inch of, 368, 388, 428, 451, 456, 497
  telescopic, 388
Apprenticeship system, technical education and the, 182
Applegarth battery, 196
Aquarium, sea water, 128
Architecture, naval, at the I.I.E., 227
Armature, Siemens-Alteneck, 525
Armatures : Gramme, 220
  laminated, 32, 56, 104, 129, 151, 193, 220
  solid v. laminated, 72
"Around" or "round," 305, 328
Arsenal, employment at the, 507
Arsenic in wall paper, testing for, 87, 153, 175, 219
Artificial : gems, coloured glass and, 468
  hand, 64
  honey, 538
  white light with metallic magnesium, 473
Asaron, 8
Asbestos, analysis of, 370
Astatic galvanometer, 303, 348
Astronomical : 233, 277, 301, 323, 347, 410, 430, 451, 473, 518
  notes, 73, 162, 270, 358, 466, 554
  object-glasses, 89, 111
  Society, special meeting of the, 211, 233, 253, 301
  Society's Monthly Notices, 146, 167
  telescope, making an, 77
Astronomy, mathematical, 256
Asylum tell-tale, 550
Athletes, training for, 328
Atmosphere, Prof. Langley on the solar rays and the, 185
Atmospheric electricity, 274, 450
Attachments for milling machines, 362
Aurigæ, theta, 122, 146, 168
Australia, work in, 266, 287, 418
Australian : scientific and mechanical association, 323
  vertebrates, 112
Automatic : brake, the vacuum, 382
  musical instruments, 348, 365, 391, 433, 436, 454, 550, 588
  steering gear, 373
Awards, Inventions Exhibition, 538
Axles : breaking of, 324, 349
  crank, 235, 260, 281, 302, 324, 349, 366, 368, 391, 412
  loco. driving, 34, 150, 172
  railway, 192
  — waggon, gauging, 526

**B.** : (135, 148, 437) 429
  448, Vega, 474
B. 147, 346
B. 464, suspected variables in field with, 429, 474
B. 607, 364, 429
Bacillus : cholera, 150
  comma, 324
  Koch's "comma," 82
Backlash in gearing, 361
Bacteria : and the cell theory, 558
  mounting, 212, 238, 324
Balance staff, 549
Baldness, treatment of, 456
Ball bearings, 418, 438, 458, 481, 503, 523, 524, 548
Ballast, mercury as, 146, 173
Bar : counterbore and facing, 476
  lifting, 505, 525, 548
Barnard's new comet, 475
Barometer : 332
  camphor or storm glass, 405
Barrels, browning gun, 87, 109
Bath, the lead, 515
Baths, hot-air and vapour, 38
Batteries : electric, recent improvements in, 94
  — lighting by, 266
  Leclanché, 147
  secondary, 134
  storage, 133, 197, 371
Battery : Applegarth, 196
  bichromate, 177, 198, 287
  — for lighting, 220, 239
  — powerful, 288
  chemical action in, 88, 110, 158, 549
  Chlores-Baudet, 343
  copper-zinc, 199
  Daniell improved, 170
  — sulphate of soda in, 522, 540
  dry, 85
  electric pen, 242, 264
  for electric lamps, 416
  for sewing machine, 85, 130
  gas, Kendall's, 557
  granule, 441
  internal resistance of, 219
  iron as an element in the, 480
  Jablochkoff's new, 297
  Leclanché, 174
  — agglomerate, 332, 353
  lighting with, 265
  new secondary, 344
  new storage, 49
  Pabst, 196
  perchloride of iron, 482
  plates, fixing, 89, 197
  Skrivanow, 108, 112, 178, 197, 221
  storage, 505, 548, 571
  telephone, 177
  troublesome, 41, 66, 109, 152
  zinc, 240
Beading, rabbeting, and slitting plane, adjustable, 185
Beam, supported, 307, 329, 352, 416, 437, 482, 524
Beans, green peas and French, 502
Bearing grease, 396
Bearings : alloy for watch, 265
  ball, 418, 438, 458, 481, 503, 523, 524, 548
  lubricating, 370
Beckenham disaster, boiler explosions in 1884 and the, 71
Beckett's Clocks, Watches, and Bells, 479, 520
Beck's star microscope, 406
Bed : frames, proper form for, 127
  sores, 572
Bee swarmer and hiver, Ferguson's, 362
Beer and Mädler's telescope, size of, 539
Beers, fermentation in horehound and hop, 416
Bees : and beehives, 32
  keeping in room, 571
Bell : domestic magneto, 295
  Jolin's electric, 483
  telephone circuit, 569
Bellows, smith's, 16
Bells : electric, 39, 130, 264, 286, 288, 306
  — connections, 240, 394
  — double, 199
  — in series, 461, 483, 504, 524
Belt, fastener for lathe, 317
Belting, rubber, 155
Belts v. ropes, 443
Bench, parallel, and tube vice, combined, 351
Bending iron pipe, 288
Bengal lights, 396
Benzol magnesia, 408
Berenices, stars in Coma, 388
Bessel, 55
Bichromate : battery, 177, 287
  — for lighting, 198, 220, 239
  — powerful, 288
  cell, chemical action in, 88, 110, 158
Bichromate : cells, 39, 85
Bicycle : Facile with speed gear, 47
  fork, brazing, 66
  Otto, 521
  spring, 460
  turning, 503, 547
Bicycles : safety, 520, 543, 566
  tandem, 284
  tricycles and, 523
Bilgram's gear cutter, 340
Bills, mill, 174, 196
Binegar accident, 542, 566
Binocular v. monocular microscope 182
Binoculars, 453
Bird : taming, 506, 526
  the soaring, a mechanical problem, 509 568
Birkmann's lathe and drill-press chuck 186
Birmingham new station, 177, 262
Black : edged note paper, ink for, 392
  stockings, stained skin from, 286
Blacking, paste, 371
Blast, cupola, 218, 262
Blasts, sand, 15, 135
Bleaching : oil, Herzog's process of, 425
  ostrich feathers, 165
  shellac, 503, 547
Blinds, wire, 284
Block : instrument, Tyer's, 393
  printing processes, photographic, 47
Blowhole, plugging, 440
Blowpipe : examination of minerals before the, 390, 412, 431, 453, 478, 49[illegible], 546, 567
  oxyhydrogen, 266
  petroleum lamp, 175, 219
Blue shadow, 111, 133
Blunt's self-centring chuck, 4
Boat : 16
  model, 221
  model engine and, 196
Boating, 418, 438, 458, 503, 569
Boats, lee boards to, 392
Boiler : 353, 394, 416, 439, 441
  chimneys, 218
  cleaning stationary, 461
  copper coating, 571
  enamel, 288
  engine, 218
  explosion of a safety, 231
  explosions in 1884 and the Beckenham disaster, 71
  for boat, 110
  furnace, explosion of gases in, 287, 307
  inexplosible, new, 147
  launch, 177
  model tug, 216
  pressure in, 242, 3.6
  query, 418
  vertical, 155, 221
  water capacity of, 67
  work, laying out sheet metal for, 537
Boilers : and ships, steel plates for, 169
  hints for cleaning, 252
  horse-power of, 38
  model, 395
  repairing, 177, 193, 216
  tallow in loco., 18, 39
  testing and rating, standard method of, 45
  thickness of copper plate for model, 235
Boiling white, 284
Bone or ivory, marking, 332
Bookbinding, 572
Book-keeping, engineers', 418
Books : on brickmaking, 219
  on herbal medicine, 89, 110
  on veterinary medicine, 40
Boot-cleaning machine, 181
Boring : for water, 265
  lathe heads, 69

210068

Boring mill, 183
  small wood handles
Bort, 32, 64, 85, 126
Botanical, 572
Bottle, feeding, 221
Bottles, glass, cutting, 308, 330
Bottone, Mr., and his private correspondents, 11
Bow, watchmaker's, 484
Brace, small, 109
Brake: automatic vacuum, 382
  Carpenter, 241
  failure, another, 128
  gravity, 432
  Heberlein, 291
  power on the N.E. railway, 235
  steam, 332
Brakes: continuous, 84, 217
  failures of, 500, 521
  new, 12, 34, 64
  on the G. and S.W., 64
  railway, 500
Brandon's piston packing, 535
Brass: and glass, 34
  colouring steel grey or black, 473
  embossing on, 152
  pickle for, 353, 372
Brassing, electro, 15
Brazing: bicycle fork, 66
  steel, 65
Bread, wheat meal, its alimentary value compared with that of white flour, 208
Breaking, horse taming or, 506
Brick-burning on wet ground, 66
Brickmaking, books on, 219
Bricks: ornamental, 66
  setting, 265
Bridge, Wheatstone, 109, 132, 153, 175, 219, 257, 279, 519
Brightening small goods, 506
Brighton line, locomotives on the, 96, 527
Britannia Company's foot-power circular saw, 26, 219
Brockelbank's weather shield, 471
Bronzing iron, 242
Browning gun barrels, 87, 109
Brown's expanding machine reamer, 513
Buckskin, staining, 175
Building: construction, 265
  organ, 285, 547
Burnham's double stars, 276
Burning, lead, 19, 241, 287, 307, 329, 352, 371, 416, 437, 457, 481, 508, 524, 547
Butter: and its substitutes, discrimination of, 392
  pure, 406
  spurious, 454
  testing, 310

**CALCIUM** and aluminium, 481, 519
Calculations, wheel, 289, 308, 329
Caloric engine, 395, 503
Calorie in French thermal units, 193, 385, 435
Calorimetry, 308
Camera shutters, Elson's flashing lantern and, 411
Cameras, object-glass for telescopes and, 450
Camphor barometer or storm glass, 405
Camping stoves, 332, 353, 371, 394
Cancri: alpha$^{1}$, 364
  phi$^{2}$ and upsilon$^{1}$, 429
Cane-sugar, determination of mixtures of milk-sugar and, 165
Cannel coal, 262
Canoe, steam, 441, 459
Canvas: waterproofing, 371
  Willesden, 434, 459
Capstans, hydraulic, 330
Carat, diamond, what is a? 89, 111
Carbon: battery, 441, 459
  bisulphide in prisms, Dr. H. Draper's experiments in the use of, 183
  disulphide disinfecting lamp, 342
  oxidation of in galvanic cell, 85
Cardew's voltmeter, 550
Care and use of microscope lenses, 385
Carpenter brake, 241
Carriages, steam, 266, 286, 328, 352, 370, 392, 415, 436, 457
Case-hardened iron, 549
Cassegrain, notes on the, 3, 72, 117, 127, 149, 301, 365, 389, 413, 421, 452, 465, 488, 519
Cassiopeiæ, Struve 3037, 563
Cast: iron, turning, 112
  net, 18
  steel, welding, 289
Casting iron on wrought shafting, 456
Castings: 418, 438
  annealed, 193
  warping and cracking of, 447, 480
Catalogue for lending library, 416
Cathedral, Lincoln, beam in, 242, 285
Ceiling centres, plaster, 395
Celestial objects, apparent enlargement of as they approach the horizon, 30, 256, 388
Cell: bichromate, 40, 85
  new standard, 469
  theory, bacteria and the, 558
  zinc-iron, 39, 85
Cells: Leclanché, 193
  porous, 288
Cement: conductive, 416
  for marble, 442
  for rain-water pipe, 220, 240
Centrifugal force, 264
Cephei, delta, 429
  — pair near, 452
Cereals, origin of the, 195, 218
Ceti, mira, 78
Chain: fitting fusee, 221
  surveying, 571, 572
Chalk water, reducing amount of lime in, 461, 483
Chambers, water, in ships, 386
Chandelon's process for detecting strychnine, 121
Changes incidental to old age, 253
Chart, instructive form of weather, 517
Check: workmen's time, 239
Chemical: 550
  action in battery, 549, 570
  — in bichromate cell, 88, 110, 153, 547
  — of chlorine on lime, 135
  affinity, 89
  exam., 67, 87
  nature of cotton, 28
  pipelights, 19
  problems, 18, 41, 154
  soap reactions, 263
  test for arsenic, 67
Chemistry: and chemical manufactures, 359
  exam., London Univ., 109
  honours exam. in, 373
  inorganic, 373
Chess: 20, 43, 69, 91, 113, 136, 157, 179, 201, 225, 244, 268, 291, 312, 333, 355, 376, 398, 420, 443, 463, 487, 508, 530, 552, 574
Chicago clock, new, 300
Chimney: draught in, 396
  pipe, 176
  stacks as uptakes for exhaust, 18
Chimneys: boiler, 218
  high, 471, 501, 522
Chisels, hints on making, 57
Chloris-Baudet cell, 343
Chlorophyll, 439
Choke damp, 417, 438
Cholera: bacillus, 150
  Dr. Klein on, 97
  inoculation for, 296
  tobacco and, 457
Christofle, 132
Chronic: cold in the head, 198, 220, 284
  rheumatism, 243, 286, 306
Chuck: Birkmann's lathe and drill press, 186
  Blunt's self-centring, 4
  drill, 329
  eccentric and oval cutting, 196
  hardening jaws of, 329
  Hartford drill, new, 49
  scroll, 66
Chucks: drill, 288, 329
  wooden, 11
Cincinnati observatory, reports on comets of 1883, 517
Circle, 331
Circuit, bell telephone, 569
Circular saw, Britannia Company's foot-power, 26, 219
Circumference of wire rope, 393
Cleaning: boilers, hints for, 252
  glass, 266
  marble, 274
  potato, 395, 437
  stationary boilers, 461
Clock: altering, 16, 39
  eclipses of small hand of 24-hour, 288, 329
  gongs, 197
  new Chicago, 300
  novel, 282, 303, 414
  repairing, 132, 153
  wheel, fixing, 16
Clockmaking, watch and, 137
"Clocks, and Watches, and Bells," Sir E. Beckett's, 479, 520
Clocks: alarum, 129, 168
  and watches at the Inventions, 421
  strike, how should, 349
Coal: and coke, sulphur in, 199
  and iron, 75
  consumption of in Atlantic liners, 197
Coal-gas, improving light of, 16, 38, 65, 85
Coal-mines: detection of explosive gases in, 389
  ventilation of, 547, 567
Cocaine, menthol as a substitute for, 451
Cocoa-nut oil, 284
Codeine, new test for, 552
Codes, telegram, 437
Cod-liver oil, test of, 6
Co-efficient of centrifugal force, 264
Coil: condenser for, 135
  eight-inch spark, 59, 81, 154, 195, 242
  induction, 40, 66, 178, 416
  — rotations, 565
  intensity, 111, 374
  medical, 133, 239, 242, 264, 285
  regulator 550
  shocking, 40, 66, 134, 395, 438
  spark, 440, 460, 483, 504
Coils, how to make a set of resistance, 217, 234, 257, 287, 330
Cold: chisels, hints on making, 87
  in head, chronic, 177, 220, 284
Colliery: explosions, 411, 432, 567
  ventilation of, 39
  warnings, 412, 504, 525
Collimation, 121, 154
Collision, Binegar, 566
Collisions with icebergs, preventing, 386
Colour: correction of achromatic telescopes, 316, 447, 470
  — of double objectives, 559
  light and, 229
Coloured glass and artificial gems, 468
Colouring: and enamelling photographs, 266
  matters of flowers and fruits, 273
  — of leaves, 508
Colours of shadows, 121
Coma Berenices, stars in, 388
Comet: Barnard's new, 475
  oh, water, 345
  Tempel's, 122
Comets: and meteor rings, 301
  origin of, 277, 301, 322
Coming round, 345
Comma bacillus, 324
Commercial organic analysis, 383
Communication cords on railways, 261, 284, 304
Commutator, 353
Comparison of tides, 257, 368, 434
Complexity in machinery, 23
Composite portraits, 59
Compound: engines, L. and N.W., 262, 373, 461, 476, 500, 541, 566
  — triple, 479
  — valves in, 378
  eyes and multiple images, 74
Compressed air, physiological effects of, 392
Concrete, Portland cement, 197

Monad, 523
Monitograph, 468
Monthly Notices, R.A.S., for December, 1884, and March, 1885, 146, 167
Moon: eclipse of the, 277
  full, in February, 1904, 77, 121
  solar eclipses and occultations by the, 188, 215
  the distance of the, 301, 345, 347
Moon-culminating stars, longitude by, 309
Mortgages, 305
Mosaic, cosmogony, 105
Mosses, 199, 211
Motion: force and, 89, 111, 132, 153
  in a nebula, possible case of proper in, 77
  mind and, 319, 348
  of proper, 77
  of sun in space, 562
  of the stars, 295, 563
  telescope, 476
Motor: electric, 177, 483, 505, 570
  new steam, 133, 310
  sewing machine, 373
  steam, Davey safe domestic, 532
Motors: electrical, and their construction, 5
  water, 50
Moulding: iron, 234
  toothed wheels, 116
Mountain snow, 525
Mounting: bacteria, 212, 238, 324
  equatoreal, 550, 562, 571
  sputa, 177
  Wray's new universal equatorial, 466
Movements, gilding watch, 153
Multiple images, compound eyes and, 74
Musical: instruments at the Inventions, 555
  — automatic, 348, 365, 391, 412, 433, 436, 454, 550, 568
  scale, 10, 37, 58, 64, 81, 129, 151, 169, 194, 217, 260, 305
  scales of various nations, 118
Mystery, gold, 193, 234, 257
Mystification, 502, 542

NAILS, number of, in a pound, 552
Nam nunc mores nihil faciunt quod licet, nisi quod lubet, 30
Name, real, 241
Names, spelling of proper, 471
Nature, why does, grow trees in groups? 457
Nautical almanac, the, 427
Navigation, aërial, 414
Natural gas and gaseous fuel, 1
Naval architecture at the Inventions, 227
Nebula, possible case of proper motion in, 77
Negatives: durability of, 142
  paper, 406
  spoiled, 177, 198
  spotted or stained, restoring, 201
Neison, to E. M., 283
Net, cast, 18
Netting square mesh, 134
New time, 14, 36, 57, 151, 193, 238, 256, 282, 300, 323, 325, 345, 348, 391
New Zealand: telephone, 33
  3ft. 6in. railways, 499
Newmarket direct railway, 263, 287
Newton's ferrocyanide developer, 120
Nickel, 197
Nicotine syntagma, 567
Night glasses, telescopes used as, 497, 517
Nitro-benzole for entomologists, 365
Nitrometer, new, and little known applications of the, 251
Nitrous oxide and carbon disulphide light, 560
Nixon's course-reading attachments for transits, 297
Noise: disagreeable, 330, 352
  prevention of, 549, 570
Nomenclature, the new time, 14
North-Eastern railway, brake-power on the, 235
Northern railway of France, 310
Norwegian lobsters, 146
Noses, mandrel, 124
Notes: astronomical, 73, 162, 270, 358, 466, 554
  on some red stars, 346
  on the Cassegrain, 3, 72, 172, 421, 465
Notice to quit, 305
Notices of phenomena, tardy, 473
Novel clock, 282, 303
Novelty Exhibition, the Franklin Institute's, 187

OBACH'S galvanometer, 505, 525
Object-glass: adjustable, for telescopes, 475, 540
  focus of, 485
  for telescopes and cameras, 450
  length of focus of, 167
  tests for a 5in., 345, 346
Object-glasses: astronomical, 89, 111
  separating power of, 388
Objective, micro., 214, 526, 563
Objectives: colour correction of double, 559
  triple, with complete colour correction, 447
Objects, apparent enlargement of celestial, as they approach the horizon, 288
Observatory: 10, 31
  dome, 395, 437
  Harvard college, 211
  large telescope for the Royal, 345, 347, 388
Occultation: new form of, 77
  of Aldebaran, 8, 55
  daylight, 428, 451, 474, 497, 518, 539, 562
Occultations: further, of Aldebaran, 57
  partially-graphic method of computing, 322, 410
Ochorowicz loud-speaking telephone, 97, 229
Odds and ends, optical, 61
Ohm, subdivision of the, 234
Oil: alizarine, 112
  bleaching, Herzog's progress of rapid, 425
  cocoa-nut, 284
  cod-liver, test of, 6
  lamps, mineral, 192, 260, 284
  on troubled waters, 426
  quinine and, 11
Oil-gas generator, 19
Oils: painters', 552
  test for, 110
Oil-stone, how to treat the, 6
Opera-glass: power for an, 427
  size of field in, 388
Opera-glasses, powerful, 15, 173, 233, 238, 241, 256, 279, 301, 365, 392, 418, 430
Ophiuchi: (36), 428, 518, 539
  53, and stars in field, 364, 409, 410, 428, 451, 539
  (70), 410, 552
Optical: anomalies in crystals of the regular system, 120
  formulæ, 109
  effect, curious, 127, 150, 167
  glass, new, 519
  instruments, lathework and, 543, 568
  odds and ends, 61
  questions, 176, 239, 351, 364
Optics with the lantern, 16, 38, 61, 108
Optometer, compound, for correcting errors of refraction, 207
Ordnance Survey, handbook of the maps, 30, 121
Organ: American, 15, 37, 64, 85, 288
  — pedal bass attachment, 567
  — reeds 85
  — separate pedal organs for, 171
  building, 285, 547
  designing, 455, 545
  pedal pipes, voicing, 40
Organic analysis, commercial, 383
Origin: of comets, 277, 301, 322
  of man, 30
Orionis: drawings of theta, 9
  pi¹, 322, 429
  stars near theta, 9
  theta, 30
  — visibility of stars in the trapezium of, 146
Ornamental bricks, 66
Orrery or planetarium, 167
Ostrich feathers, 165
Otto bicycle, 498, 521
Overflow in water-waste preventer, 239, 454
Owls, 262
Oxygen: in hydrogen, burning, 221
  life without, 457
Oxygenated water, 449
Oxhydrogen: blowpipe, 266
  lantern, 67, 87
Oyster, life of an, 140

PABST battery, 196
Pacinotti ring, 131, 176
Packages, air-tight, 167
Packing: for flue pipe in roof, 197
  piston, Brandon's, 535
Paddle boat, model engines for, 199
Paint: blistering of, 18, 89
  luminous, 467
Painter's oils, 552
Painting: bicycle, 393
  mirror, 416
Paints: analysis of, 204
  weatherproof, 417
Pallet holes for harmoniums, 241
Panoramic tripod, Cusworth's, 467
Paper: indicator diagrams, 176
  negatives, 406
  — new double-coated sensitive, 471
  parchment, 484
  shrinkage of, 257
  tracing, 86, 175
Paraffin oil lamps, explosions in, 48, 194, 325
  taper, uses of a common, 59
Parallax, stellar, 121, 197, 239
Parallelogram of forces, new demonstration of, 283
Parchment paper, 484
Paris observatory: electrical exhibition at the, 138
  telescope for stellar photography at, 320
Past, records of the, 135
Paste: 550
  blacking, 371
Pasteur's vaccine for splenic fever, 198
Patent: law, 65, 86, 108, 130, 152, 174, 195, 219, 417
  office, the, 436
Pattern making, 155, 192
Patterns, home-made engine, 3
Pearson's partially-graphic method of computing eclipses and occultations, 123, 410
Peas, green, preserving, 502
Pedal: bass attachment for American organs, 567
  organs for American organs, separate, 171
  pipes, voicing organ, 40
Pedals, tricycle, 265, 286, 306, 328
Pen, Edison's electric, 196
Pendulum escapement, Hart's, 320, 364
Penistone disaster, the, 476, 500, 521
Periodicity of sunspots, 146
Periphery of ellipse, 488
Permanent way inspectors, the institution of, 409
Persei, Heis 121, 322
Perturbations, lunar, 121
Petroleum: for fire-engine furnaces, 14
  lamp, blowpipe, 175
  lamps, 287
Philadelphia, electric railway in, 425
Phosphorescence of the sea, 562
Phosphoric acid in manures, 36
Phosphorus, pure, 459, 549
Photographers, dodges for amateur, 28
Photographic: block-printing processes, 47
  lenses, 67
  — stops to, 155
  maps of the stars, 297
  scrap-book, 505
Photographing: engraving and plans, 112
  interiors, 75
  solar corona, 211
Photographs: rectilinear, by distorting lenses, 495
  simple method of colouring and enameling, 206
Photography: and the spectroscope, 493, 515, 536
  dry-plate, 418, 438, 485
  for amateurs, 164
  isochromatic, 229
  portrait, 395
  snapshots in, 229
  staining tissues for, 98
  stellar, new telescope for, at Paris observatory, 321
  wet-plate, 485, 505
Photo-micrography, 130, 298, 359
Physics, mathematical science, cramming in, 327, 349, 369
Physiological effects of compressed air, 392
Pianista, Miranda, 262
Piano: restringing grand, 86
  tuning hammer, 372
Pianoforte: making, 372
  repairs, 459
Pianos and their shape, 430
Piccolo, 287
Pickle for brass, 372
Pictures, transferring to glass, 155
Pig, a six-footed, 550
Pipe: chimney, 176
  exhaust, 134, 155, 176, 199
  pressure of water in, 17, 39, 65
  Ross's, Col., improved filter, 294, 327
Pipe-lights, chemical, 19
Pipes: cutting, 67, 109, 131, 153, 175
  flow of gas in, 222
  galvanised iron, 485
  hot-water, 372
  repairing rainwater, 193
Piston: packing, Brandon's, 535
  speeds, marine, 15
Pitchgrease, 174
Plaiting crystal models, 56, 105, 171, 324
Plane: adjustable beading, rabbeting, and slitting, 185
  surfaces, critical methods of detecting errors in, 98
Planetorium, orrery or, 167, 197, 220
Planing: 571
  machine, 46, 160, 250, 338, 402, 459, 503, 527, 548, 569
Plants: do they vary when propagated by cuttings? 97
  influence of electric light on, 224
Plaster ceiling centres, 395
Plate-glass, drilling rough, 332
Plates: Ferrier and Soulier's, 19
  fixing battery, 197
Plating: dynamo, 16, 131
  gold, 331, 371
Platinising glass, 49
Platinotype process, 461
Platinum: recovering silver and, 571
  soldering, &c., in the laboratory, 186
  test for, 366
Plea for good manners, 10
Pneumatic transmission of the mails between London and Paris, 82
Pocket: field microscope, 502, 517, 540
  telescope, 256, 263
Polishing: French, 328
  wood, 11
  — in lathe, 130
Porous cells, cleaning, 288
Portable engine, 154, 219
Portland cement concrete, 197
Portrait photography, 395
Portraits, composite, 59
Portraiture, 288, 307
Post Office and the press, the, 427
Potash and magnesia, separating, 436
Potato cleaning, 395, 437
Pots, flower, 197, 477, 520
Potter's kiln, 155, 197, 330
Pound, nails in a, 552
Power: loss of, 354, 372
  transmission of, 441, 461, 483, 524
Powers that (can't) be, 473
Prehistoric: man, 300
  structures in Micronesia, 267
Preservation of mirrors, 146
Preserving eggs, 279
Press, post office and the, 427
Pressure: for stamping, 239
  gauges, testing, 111
  of boiler, 242
  of water in pipe, 17, 39, 65, 111
  on sides of tank, 239
  water, 174
Prime: meridian from a French point of view, 473
  movers and distribution of power, 271
Prints, red, for draughtsmen, 560
Prism, right-angled, instead of plane mirror in the microscope, 414
Prisms, Dr. H. Draper's experiments on the use of carbon bisulphide in, 183
Problem: an insoluble, 517
  a mechanical, the soaring bird, 509
  history of the tidal, 477, 499, 544
Problems: algebraical, 309, 310, 330, 371, 393, 395, 417, 437, 438, 459, 482, 504, 506
  chemical, 18, 41
  hydraulic, 17, 65, 353, 505
  mathematical, 525, 548, 569
  of population, 461, 483
Projectiles, fuses for, 111, 154, 284
Prominences, solar, 31
Promissory note, 305
Propelling, ship, 479
Providence screw-cutting lathe, 404
Public lighting, 155, 176
Pull of M.-H. rifle, 309
Pulleys: grooves of, 570
  rope, 41
Pump: 526
  easing force, 526
Punches, hardening, 526
Purifier, gas, 41
Putty, 331, 353, 371
Pyroligneous acid, 374
Pyrology, 412, 434, 453, 478, 497, 519, 567

QUERIES: watchmakers', 544, 568
  engine, 394, 419, 503
Query meaning, 239
Questions: algebraical, 440
  mechanical, 353, 372
  science, 309
  Woolwich examination, 572
Quinine: and oil, 11
  manufacture, 330

RABBIT, false, 76
Radiometer, 347
Radius of curve, 571
Rafters, roofing, 265
Railway: axles, 192
  — lubricants for, 217, 325
  brakes, 500
  curves, resistance on, 244
  facilities, modern, 115
  Great Western, 128
  Leicester and Swannington, 58, 128
  Newmarket direct, 266
  plant, 292
  signal returns, 435, 455, 500, 521
  speed, high, in W. S., 387
  trains, jerks in, 261, 304
  waggon axles, gauging, 526
Railways: communication cords on, 261, 284, 304
  New Zealand 3ft. 6in., 499
Rain, sunspots and, 211

Selenite, 112, 134
Selenium: electromotive action of illuminated, 339
  sunlight measurer, 363
Selenographical, 451
Self-winding watch, 174
Sellers's screw-thread, 155, 176, 198, 219
Sensitive: flame, 199
  paper, new double-coated, 471
Separating power of object-glasses, 388
Series wound dynamo, 30-lighter, 147
Sewing-machine: driving, 199
  motor, battery for, 85, 130, 373
Shadow: blue, 111, 133
  colours of, 121
Shaft: crank, 134
  diameter of, 572
Shafting, strength of, 174, 195, 218, 238
Sheet iron and boiler work, laying out, 537
Shellac: bleaching, 503, 547
  varnish, a clear, 100
Ship: a big, 388
  propelling, 479
Ships: steel plates for boilers and, 159
  zinc sheating for, 532
Shocking coil, 40, 66, 134, 395, 438
Shooting, rifle, 523, 566
Shrinkage: of paper, 257
  of woollen goods, 471
Shunt dynamo, 484
Shutter, Sargeant's patent drop, 338
Shutters, lens, 61
Shuttles, compressed teak for loom, 101, 177, 198
Siemens-Alteneck armature, 525, 548
Signal, railway, returns, 434, 455, 500, 520
Silicates of soda, 120
Silos, 16
Silver: bisulphite of, 483
  German, 193
  recovering, from fixing baths, 341
  refining, 11, 17
Silver-plating, 460, 508
Silvering: solution, 415, 483
  specula, 328
  telescope mirrors, 123, 396
Singing noises in head, 41, 86
Sink in dark room, wooden, 242, 264
Siphon: 440, 484, 504, 525
  experiments with the, 97
Six days of creation, 78, 105
Six's register thermometer, 416
Skeletons, preparing and mounting small, 419
Sketching, 155, 176
Skrivanow: battery, 108, 112, 178, 197, 221
  cell, improved, 512
Slide, vertical, for lathe, 350
Slides, making lantern, 403, 546
Slide-valve: diagrams, 12, 221
  link-work for, 240
  locomotive, 503
Smiths' bellows, 15
Smoke: 146
  all made from, 7
Snap shots in photography, 229
Snow, mountain, 485, 525
Soap: 248
  analysis, 460
  for hard water, 265
  oil for making, 415
  sand and transparent, 207
Soaring bird, a mechanical problem, 509, 568
Socket joint making, 517, 438
Soda: bisulphite of, 483, 525
  soluble glass or silicate of, 120
  sulphate of, in Daniell's battery, 522, 540
Sodium: improvement in the manufacture of, 94
  preparation of, 220
Softening water, 352, 393, 416
Solar: corona, Dr. Huggins on the, 6
  — photographing the, 211
  day-glow, Mercury in the, 256
  diffraction spectroscope, 148
  eclipse of March 16, 8, 123
  — of September, 54
  eclipses and occultations by the moon, 188, 215
  prominences, 31
  rays, Prof. Langley on the, and the atmosphere, 155
Solder, removing zinc from tin, 372
Soldering: 526
  and repairing platinum vessels in the laboratory, 186
Sores, bed, 572
Span, load on short, 419, 439
Spark coil, 440, 460, 483, 504
Specific heat, 41, 461, 483
Spectacle lenses, 196
Spectra, 484
Spectroscope: 473, 488, 504
  photography and the, 493, 515, 536
  solar diffraction and star, 147
Specula: curves for, 278
  glass discs for, 365, 454
  grinding and polishing glass, 101, 277
  silvering, 323
Speed: of trains, 456, 542
  of American trains, 500
Spelling of proper names, 471
Spherical aberration, 353

# ILLUSTRATIONS.

**ADJUSTMENT** for microscope, fine, 235, 239, 351
Æolian harp, 163
Alarm, electric fire, 495
Amateur: lens making, 425, 499
  workshop, 46, 161, 250, 339, 403, 491
Amateurs, electrical instrument making for, 511, 557
American organs: pedal bass attachment to, 564
  separate pedal bass for, 569
Angular advance of connecting-rod, 503
Armature: Gramme, 220
  laminated (Jones), 220
  — winding, 549
  Siemens Alteneck, 525
Artificial hand, 64
Automatic: musical instruments, 454
  steering gear, 394
Axle, crank, Linney and Lawson's, 325
Axles, crank, 366

**B 448, VEGA**, 475
Battery: cell, Skrivanow's improved, 512
  Kendall's gas, 557
Beading, rabbeting, and slitting planes, 185
Beam, supported, 307, 524
Beck's "Star" microscope, 406
Bee swarmer and hives, Ferguson's, 362
Bell: domestic magneto, 295
  Jolin's electric, 483
  telephone circuit, 569
Bellows: action for organ, 222
  smith's, 15
Bells: electrical, 176, 240
  — connecting, 394
Belt fastener, lathe, 317
Bench, parallel, and tube vice, 351
Bilgram's gear cutter, 341
Birkman's lathe and drill press chuck, 186
Birm. 464, the red star, 474
Birmingham 464, variable stars in field with, 429
Blast, cupola, 218
Block instrument, railway, 398
Blowpipe petroleum lamp, 175
Blunt's self-centring chuck, 5
Boating, screw propeller gear for, 439
Boiler: model, for boat, 110
  portable engine, 219
Brandon's piston packing, 535
Brass and glass, 34
Bridge, construction of a Wheatstone, 521
Britannia Company's foot-power circular saw, 26
Brown and Saunder's telephone, 198
Brown's expanding machine reamer, 513
Burning oxygen in hydrogen, 221

**CAMERAS** and telescopes, object-glass for, 450
Carbon, bisulphide of, disinfecting lamp, 342
Cassegrain, notes on, 72
Cassiopeiæ, Struve 3037, 563
Castings, on the warping and cracking of, 447
Cell: improved Daniell, 170
  improved Skrivanow, 512
Cephei, delta, 429
Chair and spring key, Steen's railway, 302
Chimney pipe through roof, 176
Chuck: Birkman's lathe and drill press, 186
  Blunt's self-centring, 5
  drill, new Hartford, 49
Chucks, lathe mandrels, &c., 83
Circle problem, 331
Circuit: electric bell, 240
  telephone, 198, 286, 569
Clock: altering, 16
  dead-beat escapement for, 16
  stop, 39
Coal-gas, improving light of, 38
Coal-mines, detection of explosive gases in, 389
Coil, induction: and condenser, 66
  — rotations, 565
  medical, 133
  shocking, 152
Compound locomotive, L. and N.W., 262
Condenser: cheap form of, 34
  induction coil and, 66
Condensing engine, Watt's, 330
Conics, 87
Cores for cast-iron pipes, 17
Corn marigold, double, 411
Counterbore and facing bar, 477
Couplings, Keeling and Rigley's safety, 328
Course reading attachments for transits, Nixon's, 297
Crank axles: 366
  Linney and Lawson's, 325
Cranks, turning, 131, 263
Critical methods of detecting errors in plane surfaces, 99
Crystals, forming by plaiting, 56, 105, 171, 324
Cupola: 571
  blast, 218
Currents, extra, 547
Curves of large radius, setting out, 435
Cutter, Bilgram's gear, 341
Cutter bar: 455
  grinding tools for Haydon's, 433
  simple for 5in. lathe, 433
Cutter bars, tool edges, and cutters, 225, 269, 318, 357, 399
Cutting: pipes, 109, 131, 153, 175
  screw threads with revolving cutter, 239, 393

**DANIELL** cell, improved, 170
Davey "safe" domestic steam motor, 532
Dead-beat escapement for clock, 16
Dead centre for lathes, Hampson's, 386
Diagrams, slide-valve, 13
Diamonds, fixing and setting for cutting and other tools, 291
Disinfecting lamp, bisulphide of carbon, 342
Distance of the moon, 345
Dome, observatory, 488
Domestic: magneto bell, 295
  steam motor, Davey safe, 532
Double telescopes, 81
Drill: chuck, new Hartford, 49
  press chuck, Birkman's lathe and, 186
Drilling square hole, 154
Driving gear for planing machines, 46
Drop-shutter, Sargeant's patent, 338
Dynamo: Gramme, 223, 268, 354, 524, 570
  thirty-light, 259, 564

**ECLIPSE**, solar: of March 16, 123
  computation by the partially-graphic method, 8
Eclipses, solar, and occultations by the moon, 188
Edmunds thread, the, 280
Electric: bell, Jolin's, 483
  fire-alarm, 495
  meter, Miller's, 26
Electrical: bells, 176, 240
  — connecting, 394
  instrument making for amateurs, 511, 557
  machine, Voss, 283
  measurements, Lippmann's apparatus for, 512
  motors and their construction, 5, 570
  weather vane, 411
Electro-magnetic problem, 528
Electro-meters, Dr. Marshall Watts's, 209
Electromotors: 482, 570
  Gant's patent, 423
Elson's flashing lantern and camera shutters, 411
Engine: condensing, Watt's, 330
  Fielding high speed, 556
  Great Western broad gauge, 150
  lathe, screw-cutting on the, 495
  Manchester, S and L., 193
  patterns, home-made, 4, 24
  portable, 154, 219
  query, 503
Engine-making at home, 4, 24, 95, 205, 294, 381, 446, 534
Equation of light, 517
Equatorial mounting, Wray's new universal, 466
Escapement: dead-beat, 16
  Hart's pendulum, 320, 366
Ether freezing apparatus, 424
Examination question, science, 461, 483, 504
Expanding reamer, Brown's, 513
Experiments with the siphon, 97
Explosive gases in coal-mines, detection of, 389
Extra currents, 547

**FACILE** bicycle with speed-gear, 47
Facing: bar, counterbore and, 477
  stop-valve, 178
Fastener, lathe belt, 317
Ferguson's bee swarmer and hiver, 362
Fielding high-speed engine, 556
Filter pipe, Col. Ross's, 295
Fire-alarm, electric, 495
Flexible wheels, 389
Flour mill, Westinghouse engine for, 273
Forces, new demonstration of parallelogram of, 283
Freezing apparatus, ether, 424

**GALVANOMETER**: Gaiffe's new medical, 468
  lens for mirror, 462
  Obach, 525
  Rosenthal's, 296
Gant's patent electromotor, 423
Gas: battery, Kendall's, 557
  maker lamp, Wood's, 139
  manufacture of illuminating and heating, 183
Gases, explosive, detection of in coal-mines, 183
Gauge: easily-made, 542
  Wyke's screw-cutting, 273
Gear-cutter, Bilgram's, 341
Gearing, looped figures by, 350
Geometrical problems, 264, 285, 526
German lathe with traversing mandrel, 543
Ginger plant, 481
Glass specula, grinding and polishing, 102 277
Gramme: armature, 220
  dynamo, 223, 268, 354, 524, 570
Great Western broad gauge 8ft. single engine, 150
Grinding: tools for Haydon's cutter-bar, 433
  V-tools, 109
  wheel, polishing on, 454

**H (G.C.) 2091**, 276
Hampson's dead-centre for lathes, 386
Hand, artificial, 64
Harp, Æolian, 163
Hartford drill chuck, new, 49
Hart's pendulum escapement, 320, 366
Haydon's cutter-bar, grinding tools for 433
Helical teeth, 86
Hole, drilling square, 154
Home-made engine, 4, 24, 95, 205, 294 381, 446, 534
Hydrogen, burning oxygen in, 221

**ILLUMINATING** and heating gas, manufacture of, 183
Incandescent light, water gas 385
Incubator, regulating temperature in, 514
Induction coil: and condenser, 66
  rotations, 565

**JETS**, blow through, 13
Jolin's electric bell, 483
Jones's laminated armature, 220

**KEELING** and Rigley's safety couplings, 328
Kendall's gas battery, 557

**LABBEZ** telemeter, 248
Laminated armature: 220
  winding, 549
Lamp: bisulphide of carbon disinfecting, 342
  blowpipe petroleum, 175
  Wood's gas-maker, 139
Lantern: optics with the, 16
  reflecting magic, 561
Lap, can a V-thread form a? 280
Lathe: and drill press chuck, Birkman's, 186
  belt fastener, 317
  cutter-bars for 5in. simple, 433
  engine-cutting on the, screw, 495
  mandrel, "Tubal-Kain's," 215
  — traversing, German, 518
  mandrels, chucks, &c., 83
  matters, 237, 258
  plate for, 241
  Providence screw-cutting, 404
  wheel, a cheap, 192
  with vertical slide, 350
Lathes, Hampson's dead-centre for, 386
Laundry, ventilation of, 66
Lens: for mirror galvanometer, 462
  making, amateur, 425, 499
  mounting, 564
Light: equation of, 517
  nitrous oxide and carbon disulphide 560
  of coal-gas, improving, 38
  water-gas incandescent, 385
Lighting, bichromate battery for, 198
Linkwork for slide-valve, 240
Lippmann's apparatus for electric measurements, 512
Load, safe, 486
Locomotive: compound, L. and N.W., 262, 373
  Gt. Western broad gauge, 150
  M.S. and L., 193

London and N.W. compound locomotive, 262, 373
Looped figures by gearing, 350

**MACHINE** : boot-cleaning, 131
  planing, 458
  Voss electrical, 283
Machines, planing, 46, 161, 250, 403
Magic-lantern, a reflecting, 561
Magnetic moment, 283
Magneto bell, domestic, 295
Manchester, Sheffield, and Lincoln express engine, 198
Mandrel : nose, 124
  traversing of German lathe, 543
  "Tubal Kain's," 215
Marigold, double corn, 411
Mathematical problem, 394
Medical : coil, 133
  galvanometer, Gaiffe's new, 468
Meter, electric, Miller's, 26
Micro-objective, 214, 258, 302, 564
Microscope : Beck's "Star," 406
  fine adjustment, 288, 339, 351
  mineral and rock sections for, 342
Miller's electric meter, 26
Milling : machines, new attachments for, taper work, 165
Mineral and rock sections for the microscope, 342
Mirror galvanometer, lens for, 462
Mirrors, some matters in the theory of, 379, 402
Model boiler for boat, 110
Models of crystals, forming by plaiting, 56, 105
Moment, magnetic, 283
Monitograph, the, 468
Moon, distance of the, 345
Motors, electrical, and their construction, 5, 482
Moulding toothed wheels, 117
Musical : instruments, automatic, 453
  scale, 170

**NITROMETER**, new and little known applications of the, 251
Nitrous oxide and carbon disulphide light, 560
Nixon's course-reading attachments for transits, 297
Nose, mandrel, 124
Nose-piece for testing sectors of object-glass, 34
Notes on Cassegrains, 72

**OBACH** galvanometer, 525
Object-glass for cameras and telescopes, 450
Objective, the micro., 214
Observatory dome, 438
Ochorowicz telephone, 229
Ophiuchi : 36, and 30 Scorpii, 428
  53, and stars in field, colours of, 364, 410, 539
Optical : 126, 176
  effect, curious, 168
Optics with the lantern, 16
Optometer for correcting errors of refraction, 207
Organ : bellows action, 222
  pedal pipes, voicing, 40
  soundboard, 547
Organs : pedal bass attachment for American, 568
  — for American organs or harmoniums, separate, 171
Orionis, theta, stars near, 9
Oxygen in hydrogen, burning, 221

**PACINOTTI** ring, 131
Parallelogram of forces, new demonstration of, 283
Pattern making, 241
Patterns, home-made engine, 4
Pedal : bass attachment for American organs, 568
  organs, separate, for American organs or harmoniums, 171
Pendulum escapement, Hart's, 320, 366
Petroleum blowpipe lamp, 175
Phosphorus, pure, 549
Pianoforte player, Wenham's automatic, 454
Pipe : chimney, 176
  filter, Col. Ross's improved, 295
Pipes : cores for cast-iron, 17
  cutting, 109, 131, 153, 175
  voicing organ pedal, 40
Piston : and crosshead, 446
  packing Brandon's, 535
Pivot holes, watch, 65
Plaiting, forming crystals by, 56, 105, 171, 324
Plane : adjustable beading, rabbeting, and slitting, 185
  surfaces, critical methods of detecting errors in, 99
Planing : machine, 458
  machines, driving gear for, 46, 161, 250, 403, 491
Plate for lathe, 241
Polishing or grinding wheel, 454
Portable engine, 154, 219
Press chuck, Birkman's lathe and drill, 186
Pressure gauges, testing, 90
Problem, geometrical, 285, 332
Prominences, solar, 31
Propeller gear for boat, 439
Providence screw-cutting lathe, 401

**RABBETING**, beading, and slitting plane, 185
Railway : chair and spring key, Steen's, 302
  signalling block instrument, 393
Rain-gauge, easily made, 542
Rain-tanks, 17
Reamer : 156
  Brown's expanding machine, 513
Red star 464 Birm., 474
Reflecting magic-lantern, 561
Refraction, optometer for correcting errors of, 207
Refractor, the Sydney, 497
Resistance, variable, for use with ammeters, 565
Reversing gear for electromotor, 570
Ring, Pacinotti, 131
Rock sections for the microscope, 342
Rosenthal's galvanometer, 296

**SAFETY** couplings, Keeling and Rigley's, 328
Sargeant's patent drop shutter, 338
Saw, Britannia Company's foot-power circular, 26
Sawing, 392
Scale, musical, 170
Science examination question, 461, 483, 526
Scorpii, 30, and 36 Ophiuchi, 428
Screw-cutting : gauge, Wyke's, 273
  lathes, Providence, 404
  on the engine lathe, 495
Screw-thread, Sellers's, 176
Screw-threads : cutting, 236, 280, 367
  — with revolving cutter, 259, 303
Sections for the microscope, mineral and rock, 342
Self-winding watch, 108
Sellers' screw thread, 176
Setting out curves of large radius, 435
Shafting, strength of, 174, 195
Shocking coil, 152
Shutter, Sargeant's patent drop, 338
Shutters, Elson's flashing lantern and camera, 411
Siemens-Alteneck armature, 525
Siphon, experiments with the, 97
Skrivanow's improved voltaic cell, 512
Slide-valve : diagrams, 13
  linkwork for, 240
Slitting, beading, and rabbeting plane, 185
Smith's bellows, 15
Solar : eclipse, annular, 123
  — of March 16, computation by the partially graphic method, 8
  eclipses and occultations by the moon, 188
  prominences, 31
Soundboard, organ, 547
Specula, grinding and polishing glass, 102, 277
Speed gear for the Facile, 47
Square : hole, drilling, 164
  threads, threading tool for, 142
Stability and speed of vessels, 513
Stand, cheap and easily constructed telescope, 189, 234
Star microscope, Beck's, 406
Stars : near theta Orionis, 9
  variable, in field with B. 464, 429
Steam : motor, Davey "safe" domestic, 532
  value of condensing, 417
Steen railway chair and spring key, 302
Steering gear, automatic, 394
Stop : valve, facing, 178
  watch, 39
Stove, a curious, 520, 540
Strength of shafting, 174, 193
Struve 3037 Cassiopeiæ, 563
Sundials, 394
Surfaces, critical methods of detecting errors in plane, 99
Swiss stove, curious, 520
Sydney refractor, the, 497

**TANKS**, rain, 17
Taper work, milling, 165
Teeth : helical, 86
  of wheels, 69, 111, 133
Telemeter, Labbez, 248
Telephone : circuit, 198, 286
  — bell, 569
  Ochorowicz, 229
  system, 286
Telescope stand, cheap and easily constructed, 189, 234
Telescopes : double, 31
  object-glass for cameras and, 450
  terrestrial, the, 248
Temperature in incubator, regulating 504
Terrestrial telescope, 248
Theory of mirrors, some matters in the, 379, 402
Thread : Sellers's screw, 177
  the Edmunds, 280
Threading tool for square threads, 142
Threads of screws, cutting, 236, 280, 303, 367
Tool-edges, cutter bars, and cutters, 225, 269
Tool-holders, simple and easily made, 258
Tools : and cutter bars, 269, 313, 357, 399
  diamond, fixing and setting, 291
  grinding V., 109
Transits, Nixon's course-reading attachments for, 297
Trigonometrical, 548
Turning small cranks, 131, 263

**VALVE**, facing stop, 178
Vane, electrical weather, 411
Vee : thread, can a.be formed by a lap? 280
  tools, grinding, 109
Vega, B. 448, 475
Ventilation of laundry, 66
Vertical : angular attachment for milling machines, 362
  slide-lathe, 350
Vessels, stability and speed of, 513
Vice : bench, parallel, and tube, 351
  for milling machines, 362
Voicing organ pedal pipes, 40
Voltaic : cell, Skrivanow's improved, 512
  electricity, motion produced by, 482
Voltmeter, 40
Voss electrical machine, 283

**WARPING** and cracking of castings, 447
Watch : pivot holes, 65
  stop, 39
  winding by itself, 108
Water-gas incandescent light, 385
Watt's condensing engine, 330
Watts's, Dr. Marshall, electrometers, 209
Weather vane, electrical, 411
Wenham's automatic pianoforte player, 454
Westinghouse engine for flour mill, 223
Wheatstone's bridge, construction of, 521
Wheel : calculations, 268
  polishing or grinding, 454
Wheels : flexible, 389
  teeth of, 69, 111, 133
  toothed, moulding, 117
Winding laminated armature, 549
Windway, 525
Wood's gas-maker lamp, 139
Workshop, amateur, 46, 161, 250, 339, 403, 491
Wray's new universal equatorial mounting, 466
Wyke's screw cutting gauge, 273

**XYLOPHONE**, the, 494

THE ENGLISH MECHANIC

AND WORLD OF SCIENCE.

## NATURAL GAS AND GASEOUS FUEL.

THE utilisation of natural gas and the production of gaseous fuel are two matters which, just at the present time, are attracting a great deal of attention—the one in the United States, the other in Germany. Gaseous fuel is comparatively an old subject; but the utilisation of natural gas has been revived by the fact that large quantities of it are about to be laid on to the town of Pittsburgh, which has an unenviable reputation for soot and smoke throughout the whole of the vast continent of North America. The inhabitants may be a little too sanguine as to the future, but there can be no doubt that if the supply shows no signs of abating, natural gas will be used very extensively in Pittsburgh, perhaps to the complete exclusion of coal. Gaseous fuel, which in this connection means principally water gas, is attracting much attention at Essen, and the success which has there followed the attempts to manufacture and store it, has resuscitated the old schemes for supplying Berlin with gaseous fuel from lignite mines about 30 miles distant from the city. The opinions which the late Sir W. Siemens held on the subject of converting coal into gas, and supplying that to householders, instead of the soot-producing mineral, are well known, and have been set forth in our back volumes; but he did not contemplate forcing the gas at high pressures through long lengths of piping. It is well understood that in the case of a town situated near a coal-mine, it would be much more economical to convert the coal into gas at the mine than to cart the mineral into the town and waste seven-tenths of its potential heat, while at the same time polluting the atmosphere, and now that the Americans are about to show us how to convey their natural gas into a town, something may possibly be attempted in this country—at least by the method suggested by Sir W. Siemens. Natural gas has been used in Pittsburgh for some time now in several mills and glassworks: in one mill it has been employed for nine years, latterly doing all the work at times, until some of the wells failed, and coal had to be resorted to while fresh wells were bored. The number of companies chartered in Pennsylvania to supply natural gas was up to February, 1884, no fewer than 150; but since that date a very large number of new charters have been granted, and the utilisation of the gas is proceeding apace. Next to hydrogen, natural gas is the most powerful of gaseous fuels, and one of the most economical, while it is especially adapted for many purposes because it is free from sulphur and other deleterious elements. Invariably of a more or less complex character, and varying in composition with different localities, the natural gas of Western Pennsylvania belongs to the paraffin series of hydrocarbons. In Butler County, Pa., one well yields a gas having the following composition:—Hydrogen 6·10, marsh gas 75·44, ethane 18·12, carbonic acid 0·34; while another well, comparatively near it, yields a gas consisting of hydrogen 13·50, marsh gas 80·11, ethane 5·72, and carbonic acid 0·66. In another county a natural gas is obtained which has the high percentage of 22·50 for hydrogen, with marsh gas 60·27, ethane 6·80, carbonic acid 2·28, nitrogen 7·32, and oxygen 0·83. Wells in New York State, Virginia, Canada, and other parts of North America yield a gas which is almost entirely composed of methane, light carburetted hydrogen, or marsh gas, as it is commonly called, which may be said to be composed of one-quarter hydrogen, three-quarters carbon; while some others yield a gas which is mainly propane, having the approximate composition of hydrogen 18, carbon 82. These figures will serve to show that the natural gas varies in composition with locality; but the differences are not so great as to call for any special devices in utilising the gas; and any furnace which will burn one variety will yield good results with others, the only alterations being in connection with the air supply, and as a rule that is amply provided for. Amongst those who have had most experience with the gas wells, it is the general opinion that the outflow is subject to a gradual diminution, tending to ultimate extinction, but while in some cases wells have been used up in a few years, there are others which have never failed to yield an enormous quantity of gas, as, for instance, in West Virginia, where wells have been burning for more than a quarter of a century. The pumping of oil has some effect on the yield of gas, but it is thought probable that in the majority of cases the diminution is due rather to a choking-up of the vents by deposits of salts or paraffin, than to any failure of the original source, for the lower sand rocks of the oil regions are evidently flowing with petroleum, the more volatile constituents of which are obviously in a state of compression and escape as gas when released by a bore hole. The temperature of the gas as it issues freely from the mouth of a well never exceeds 45 degs. Fahr., while its pressure when escaping freely has not in any case been found equal to 2lb. on the square inch. The low temperature is explained by the assumption that the gas undergoes very considerable expansion as it reaches the mouth of the well—an assumption which is probably correct, for blocks of ice are often seen to be thrown from the stand pipes while the gas is burning. In the mains laid in Pittsburgh the gas has a temperature of 45 degs. Fahr., but its velocity varies with the amount of friction in the pipes. Experiments made by a committee appointed to investigate the subject on behalf of the Engineers' Society of Western Pennsylvania shows that from a well indicating a normal pressure of 3½oz., gas occupied 4¼ minutes in traversing 16,000ft. of pipe, the pressure at the well increasing to 15lb. in consequence of the resistance due to friction. With an initial pressure of 90lb. per square inch the gas occupied 2¼ minutes in traversing the 16,000ft. of piping. In another case gas from a well having a normal pressure of 20oz. travelled with a velocity of 23,400ft. per minute, while a rubber ball was driven through three miles of 5⅝in. pipe in 2½ minutes. The more durable of the wells in existence did not tap the gas-bearing strata until a depth of more than a thousand feet had been reached, and the famous Murraysville well, which supplies the gas used in the Edgar Thompson Steel Works, has a bore-hole 1,337ft. deep. Not much has been done at present in utilising the natural gas in smelting furnaces, but it has been extensively employed in iron and steel mills, glass factories, salt works, and paper and other mills. As would be expected, however, few of those who use the gas obtain the best possible results, as they consume it in a very crude manner; but it is used with great economy in those cases where it is employed in the Siemens regenerative furnace. The committee above named made an experiment to test the economy of the gas as compared with coal for generating steam. They employed a tubular boiler 10ft. long, 3ft. 6in. in diameter, with 4in. tubes, and with selected coal evaporated only nine pounds of water per pound of fuel, although the water was passed through a heater placed in the flue. The temperature of the water before entering the heater was not less than

VOL. XLI.—NO. 1,041.

60° Fahr. The same boiler, when heated by natural gas, gave an evaporative efficiency of 20·31lb. of water per pound of gas, which was taken to be 23·5 cubic feet. A similar result was obtained when nearly all the tubes were plugged, but the gas required much more air than the coal to accomplish complete combustion. It is noteworthy that the best results were obtained when the products of combustion contained considerable percentages of carbonic oxide, and with the boiler in question it was found that the increased quantity of air required to effect the almost complete conversion of carbonic oxide into the dioxide reduced the economical result. A sample of combustion products taken from the flue of a boiler doing regular work, yielded nitrogen 85·88, carbonic acid 6·16, and oxygen 7·96, although more than usual care was taken in this case in regulating the draught. Improved furnaces and burners are now being introduced; but in consequence of the companies having made contracts to deliver gas at rates a trifle less than the cost of coal, in order to induce manufacturers to make a change, there is still much preventible waste. The natural gas brought into Pittsburgh burns slowly when mixed with air in the proportion of 1 to 6, rapidly with 8 volumes, explosively with 9; but it is only with 10 volumes of air that the true exploding mixture is obtained. With 12 volumes of air to 1 of gas, the mixture burns somewhat explosively, and with 13½ it burns quietly. So far very little has been done in using the gas for illuminating purposes, as it cannot be permanently charged with the vapours of the heavy hydrocarbons and stored in tanks. That difficulty can, however, be overcome by placing the charging apparatus near the burner, and consuming the gas before it has time to separate into strata of different composition. There are other reasons, however, which militate against any general use of the natural gas for illuminating purposes, and the most important of those is the enormous pressure in the mains. At the wells the gas has a pressure of 75 to 100lb. per square inch, and that must be reduced to about 5in. of water in the street pipes which deliver the gas to the mills. For that purpose regulating valves are employed; but they are not satisfactory, and tank governors similar in principle to the familiar gas-holders are being adopted. The best wrought-iron pipes must be used, and all fittings in houses must be of first quality, cast iron being inadmissible, even for mains. The natural gas, especially that which issues from wells having a pressure of 1lb. and upwards when the gas is allowed free escape, carries with it minute quantities of heavy and solid hydrocarbons, and these, under the influence of the high pressures necessary to force the gas along many miles of pipes, are frequently deposited in the street mains. A peculiar substance resembling butter is often taken from the mains conveying the Murraysville gas to Pittsburgh. A sample on analysis was found to be composed mainly of solid paraffin blown into a sort of light froth, and holding in its pores common salt, water, small quantities of lime and magnesia salts, and even coarse sand. As to the price of the gas when supplied to private houses for heating purposes, the average for some time was 50 cents per 1,000 cubic feet, but latterly one company has reduced the charge to 12½ cents, at which price it is cheaper than coal. A few years ago, so little was thought of natural gas, that oil prospectors considered themselves very unlucky if, after the expenditure of time and capital in boring, they struck gas instead of petroleum; but the latest news from the gas region is that several of the companies are about to consolidate and lay gas mains to Philadelphia, New York, and other cities. The cost of laying so many miles of pipeline will, however, be heavy, and it is doubtful if the natural gas of Pennsylvania can compete with ordinary unpurified coal-gas, or with the water-gas which is now being made in large quantities. Of late, too, the demand for the natural gas has enormously increased in Pittsburgh, and the field of its usefulness is gradually extending, for, to mention only two instances, it is now employed to extract grease and oil and cleanse delicate fabrics, which it does readily while under pressure, and it is also used for manufacturing electric-light carbons, for when imperfectly burned at a high temperature, it deposits carbon of remarkable density. So much attention being paid to the utilisation of a natural gas will assuredly lead to renewed attempts to gasify the solid fuels, and it is not improbable that before the century expires gas will be the principal form in which fuel will be used in the more go-ahead cities of the United States.

## SIMPLE EXERCISES IN TECHNICAL ANALYSIS.—V.

By An Analytical Chemist.

### Venetian Red Paint.

51. THIS is a red ochre found in Italy. "Antwerp red" and "terra rosa" are similar ochres. The former is imported from Flanders, the latter from Italy. The following is the composition of a few samples of

Venetian Red Paints.

| | (1) | (2) | (3) |
|---|---|---|---|
| Oil | 17·24 | 17·35 | (Dry) |
| Insoluble silicates | 22·40 | 5·35 | 17·9 |
| Oxide of iron ($Fe_2O_3$) | 36·56 | 56·6 | 39·0 |
| Chalk | 23·80 | 20·7 | 43·1 |
| | 100·00 | 100·00 | 100·0 |

52. *Note.*—A natural ochre should not contain *sulphate of baryta*, so that whenever this salt is found in the insoluble, the sample is probably an imitation. The following is the result of the analysis of an

Imitation Venetian Red.

| | |
|---|---|
| Oil | 17·5 |
| Sulphate of baryta | 24·8 |
| Oxide of iron | 25·9 |
| Chalk | 31·8 |
| | 100·0 |

### Chinese Red Paint.

53. This is also known in commerce by the names of "gold yellow" and "orange paste." The following is the composition of some samples of

Chinese Red Paint.

| | (1) | (2) | (3) |
|---|---|---|---|
| Oil | 11·62 | 10·7 | 13·4 |
| Basic chromate of lead | 89·38 | 89·3 | 86·6 |

54.—*Basic Chromate of Lead. Estimation.*—(*a*) Precipitate the lead as described in Art. 11; multiply the sulphate found by 1·401 for the amount of basic chromate of lead ($Cr_2Pb_3O_9$). (Another basic chromate having the formula $Cr_2Pb_4O_5$ is known.)

(*b*) To insure accuracy, it is always advisable to estimate the chromium in the sample by the method described in Art. 46.

From the amount of chromium thus found, the percentage of basic chromate of lead can be calculated.

55.—In practice, except when adulteration is suspected, it is usual to burn off the oil, and to test the residue qualitatively. If no substances other than lead and chromium are found, and if the colour of the paint is satisfactory, qualitative testing is usually sufficient; but it must be remembered that it is by no means conclusive. Sulphate of lead, and the chromates of calcium, barium, and aluminum should be looked for, as these are occasionally added in order to vary the hue and tone of the sample.

### Turkey Red Paint.

56. This is a very pure oxide of iron. The amount of water does not exceed 0·5 per cent. Traces of silica and lime may also be found, even in pure samples. The amount of oxide of iron should not be less than 99 per cent.

The following is the composition of an imitation sample :—

Turkey Red Paint (Imitation).

| | |
|---|---|
| Oxide of iron ($F_2O_3$) | 65 |
| Sulphate of baryta | 30 |
| Chalk and water | 5 |
| | 100 |

### Indian Red Paint.

57. The colouring matter used in this paint is very different from what might be expected. True Indian red is a vegetable colour prepared from sandalwood; the colouring matter in this paint is a pure oxide of iron.

### Blue Paints—Common Blue.

58. The following is the composition of a few few samples of

Common Blue Paint.

| | (1) | (2) | (3) |
|---|---|---|---|
| Oil | 13·95 | 14·9 | 14·5 |
| Sulphate of baryta | 44·50 | 60·0 | 77·6 |
| Prussian blue | 8·05 | 7·1 | 7·9 |
| Chalk | 33·50 | 18·0 | — |
| | 100·00 | 100·0 | 100·0 |

59. — *Prussian Blue* (*Estimation of*). — Prussian blue being an organic colouring matter (formula $K_4Fe(CN)_6$), is destroyed at the same time that the oil is burnt off, and converted into $Fe_2O_3$. Its determination is, however, seldom attended with difficulty. It loses, on ignition, 52·71 per cent. of its weight. When, therefore, the oil in a Prussian blue paint is determined as described in Art. 10. the total loss must be diminished by the loss due to the ignition of the Prussian blue. The proportion of Prussian blue in the sample is calculated from the amount of oxide of iron ($Fe_2O_3$) found, as described in Art. 34. Multiplying the amount of $Fe_2O_3$ by 2·1142, gives the equivalent of Prussian blue. Now, from the total amount of Prussian blue subtract the amount of $Fe_2O_3$ found, the difference is the loss on ignition due to the Prussian blue, take this loss from the total loss on ignition, the remainder is the loss due to the oil. An example will make this clear. Suppose the "total loss on ignition" to be 20 grains, and that 3gr. of $Fe_2O_3$ are found by weighing as directed; $3 \times 2{\cdot}1142 = 6{\cdot}3426$gr. = Prussian blue; and $6{\cdot}34 - 3 = 3{\cdot}34$ = loss due to ignition of the Prussian blue; therefore, $20 - 3{\cdot}34 = 16{\cdot}66$ = loss due to the oil alone.

60. If the paint should contain ferruginous earths, this method could not be employed, for the oxide of iron in the earth would not be distinguished from the oxide of iron left by the ignition of the Prussian blue. We have, however, never met with a Prussian blue paint containing such earths, and, as the amount of Prussian blue seldom exceeds 8 per cent. in such paints (equivalent to about 3½ per cent. of oxide of iron), their presence would be readily indicated by an increase in the percentage of oxide of iron.

### Celestial Blue Paint.

61. Composition:

| | (1) | (2) | (3) |
|---|---|---|---|
| Prussian blue | 5.30 | 6·57 | 5·33 |
| Sulphate of baryta | 92·24 | 92·36 | 90·40 |
| Chalk | 2·00 | | 3·56 |
| Moisture | ·46 | 1·07 | ·71 |
| | 100·00 | 100·00 | 100·00 |

62. The analytical processes are the same as for common blue paints. Being usually sold in the dry state, the amount of Prussian blue can be approximately determined by multiplying the loss on ignition, less the moisture, by 1·897.

### Metallic Blue Paint.

63. Composition:—

| (No. 1) | |
|---|---|
| Oil | 32·47 |
| White lead | 49·56 |
| Prussian blue | 17·97 |
| | 100·00 |

| (No. 2) | |
|---|---|
| Oil | 20·6 |
| Sulphate of Baryta and Oxide of Iron | 61·9 |
| Chalk | 1·8 |
| Ultramarine | 15·7 |
| | 100·0 |

64. No. 1 would be analysed as follows:—

(*a*) *Oil.*—Total loss on ignition less that due to ignition of Prussian blue as explained above.

(*b*) *White Lead.*—Dissolve the ash in dilute nitric acid, evaporate to a small bulk to expel the acid, add dilute sulphuric and alcohol, and weigh the sulphate of lead thus precipitated as in Art 7.

(*c*) *Prussian Blue.*—Boil off the alcohol from the filtrate, concentrate, add ammonia, and weigh the precipitate ($Fe_2O_3$), as in Art. 34. Multiply by 2·1142 for Prussian Blue. (Note.—The difference between the amounts of Prussian blue and oxide of iron to be subtracted from the "Total loss on ignition").

65. No. 2, in consequence of the presence of ultramarine, presents some difficulties. It was treated in this manner:—

(*a*) *Oil.*—Loss on ignition, 20·65 per cent.

(*b*) *Alumina, Silica, and Sulphate of Baryta.*—The residue was treated with hydrochloric acid, the insoluble was dried, and weighed 60·94 per cent.

This was found to contain a large quantity of sulphate of baryta, and it was then deemed advisable to take a fresh quantity.

(*c*) Took a weighed quantity of paint, ignited; treated ash with dilute hydrochloric acid in the cold; no iron dissolved; filtered; boiled the insoluble in carbonate of soda to dissolve silica and alumina; filtered the insoluble sulphate of baryta and oxide of iron; precipitated the alumina from the first filtrate (HCl solution); and estimated the chalk. No iron or zinc present in the filtrate.

(*d*) *Sulphate of Baryta and Oxide of Iron.*—Weighed the insoluble left on boiling in sodic carbonate. Amounted to 62·9 per cent. Fused this with carbonates of potash and soda to make sure that all the silica was removed; weighed a second time 63·02 per cent. Average of two experiments (*d*) and (*b*) = 61·98 per cent.

(*e*) *Chalk.*—Estimated in the acid solution in (*c*). Found 1·77 per cent.

(*f*.) *Ultramarine.*—Having ascertained the amount of all the substances present except those proper to ultramarine, this was here determined by difference. The direct determination of ultramarine is a matter of some difficulty. See below.

### China Blue Paint.

66.—*Composition:*—

| | (1) | (2) | (3) | (4) | (5) | (6) |
|---|---|---|---|---|---|---|
| Oil ...... | 51·66 | 17·85 | 18·00 | 26·28 | 18·2 | 19·9 |
| White lead | 1·85 | — | 6·80 | — | — | — |
| Sulphate of baryta .. | — | 28·75 | 34·60 | 24·03 | 28·9 | 29·3 |
| Chalk .... | 1·60 | 23·30 | 20·85 | 2·68 | 21·8 | 21·2 |
| Ultramrne. | 44·73 | 28·80 | 18·20 | 28·04 | 31·1 | 29·6 |
| Oxide of iron .... | ·16 | 1·30 | 1·55 | — | — | — |
| Oxide of alumina & silica .... | — | — | — | 18·97 | — | — |
| | 100 | 100 | 100 | 100 | 100 | 100 |

67. It may truly be said that a mixed china blue paint is more difficult to analyse than any other paint. It will be observed that the composition varies considerably. We give, for the sake of clearness, the method employed in the analysis of No. 4 in the above group. The others are, if anything, simpler.

(*a*) *Total loss on ignition.*—Took 25 grains and ignited. Loss = 6·75gr. = 27·00 per cent.

(*b*) *Total insoluble.*—Treated with aqua regia and oxidised with nitric acid the whole of the sulphur, which separated. Weight when dried = 8·38gr. = 33·52 per cent.

(*c*) *Alumina and soluble Silica.*—Added potash to the filtrate; dried and weighed = 5·37gr. = 21·48 per cent.

Made acid, added ammonia till alkaline; a second precipitate of alumina, with a trace of oxide of iron, formed. Weight = 0·62gr. = 2·48 per cent.

Total alumina = 21·48 + 2·48 = 23·96 per cent.

(*d*) *Chalk.*—Precipitated as in Art. 8. Weight = 0·67gr. = 2·68 per cent.

(*e*) *Ultramarine.*—After separating the chalk and any soluble barium salts, if present, add chloride of barium to the filtrate. Weight of sulphate of barium thus formed = 5·19gr. = 20·76 per cent. 20·76 × ·6095 = 12·65 = per cent. of sulphate of soda corresponding to the sulphide and thiosulphate of soda in the ultramarine. A standard sample of ultramarine was found to contain 45·11 per cent. of sulphate of soda, or, rather, salts of soda, which, estimated as sulphate of soda, amounted to 45·11 per cent. The amount of ultramarine in the paint was, therefore, determined by the following proportion:—

45·11 : 12·64 : : 100 : 28·04 = ultramarine.

A standard sample of ultramarine, when similarly treated, gave the following results:—

| | Per cent. |
|---|---|
| Insoluble in aqua regia .......... | 37·07 |
| Sulphate of soda ................ | 45·11 |
| Alumina ......................... | 17·82 |

(The percentage of alumina is much lower than that usually found in ultramarine blue.)

Loss on ignition 2·6 per cent.

(*g*) Insoluble in paint due to ultramarine, therefore $\doteq \frac{28\cdot04 \times 37\cdot07}{100} = 10\cdot39$, and 33·52 (*b*) − 10·39 = 23·13 = insoluble sulphate of baryta.

(*h*) Loss on ignition due to ultramarine = 28·04 × ·026 = 0·729, and 27·00 (*a*) − 0·729 = 26·28 = loss due to oil.

(*i*) Alumina in ultramarine $= \frac{17\cdot82 \times 28\cdot04}{100} = 4\cdot99$, and 23·96 (*c*) − 4·99 = 18·97 = percentage of alumina and soluble silica.

The composition of ultramarine varies sensibly, and this adds to the difficulty in analysing a china blue paint.

When treating of blue pigments we shall have something more to say about ultramarine.

(*To be continued.*)

## NOTES ON THE CASSEGRAIN.

By Dr. Royston-Pigott, F.R.S.

THE extreme convenience of this form of telescope compared with the Newtonian, especially in very large instruments, renders it an instrument of great interest.

My 18¼ Cassegrain, made by Mr. Calver, presented peculiar features. The effective focus was 62ft.; the field lens of the eyepiece was 3in. in diameter. The field of view was as flat as a plane in appearance, and the light of the moon, spread over about 5in. in its last appearance at the aperture of the big mirror, was subdued to a most pleasant degree. In some of the craters of the moon we could see a great number of distinct terraces reaching downwards to a depth hitherto unseen by me and others. The appearance of Pico down to its base, though only half-illumined, was surprisingly fine. Jupiter appeared almost too brilliant for strong eyes; Saturn very bright. Mr. Calver made me no less than five convexes with appropriate slides for focussing, which, with three eyepieces, produced great variety in magnifying power.

The foci and positions of these convex mirrors were carefully calculated so as to throw the final image 15in. behind the mirror—a novel arrangement, which enabled me to receive the image on a plane mirror fixed upon a revolving elbow, and which always enabled one to choose the most convenient position for observation. This contrivance prevented all awkward positions.

Doubtless the most facile arrangement of all is that of the Nasmyth Altazimuth, where the observer sits in one position with the observing tube constantly horizontal; but this provides no Right Ascension or Declination circles, and the finding of an object invisible to the naked eye is a matter of great uncertainty.

The focus of large parabolic mirror 10ft. 10in., and this being 18¼in. diameter, gave a proportion of focus nearly seven times the diameter of mirror. There are several points in detail worthy of close consideration. To begin, for a parabolic concave there is no possibility of avoiding aberration, which produces ultimately in the eyepiece a blurred image, except by making the convex reflector of hyperbolic curvature, and there is no known method of testing this curvature except by innumerable alterations and refixings in the Cassegrain tube.

On the other hand, if the big mirror is adapted to be used as a Gregorian, then the convex reflector must be accurately elliptical; and this curvature can be exactly tested without the big mirror being brought into play at all. These elliptical convexes also can be readily executed so as to represent innumerable elliptical curves of revolution, and the powers of the Gregorian adjusted at will. There is some slight advantage in the image appearing erect. I am not aware that any silver-on-glass Gregorians have yet been made, but for land objects or night-glasses at sea they would do admirable service. You usually see the coastguard armed with a 3ft. telescope, with the aperture cut down to, perhaps, 1in. or 1¼in. Mr. Calver is making me a finder for my 18¼, consisting of a 6in. mirror of 24in. focus, and of superb definition. What could a coastguard station not discern with this at night? The light would be about twenty times as great as the Admiralty optical weapon.

(*To be continued.*)

## HOME-MADE ENGINE PATTERNS.

## II.

### The Bed,

SHOWN in plan in Fig. 6, in elevation in Fig 7, in cross section in Fig. 8, naturally claims our first attention as being the basis of our operations. We do not want a massive-looking bed for a small engine, and I have drawn a large flat ogee moulding to impart an air of lightness and elegance to its appearance. It will occur to some that the section looks uncommonly heavy. So it does, but this is one of those things to which I referred in my first paper, when speaking of the difficulty of maintaining uniform proportions between corresponding parts in large and small engines. In an engine of six or eight h.-p., we should make the bed in section like Fig. 9; but in this case it would not be worth our while to do so, since no advantage worth mentioning would be gained in economy of material. Cutting out like that would require the insertion of the rib A, else the bed would curve rounding on its face, so that all we could save would be the bit of metal marked B, therefore the shortest and best plan is to adopt the plain shape we have sketched.

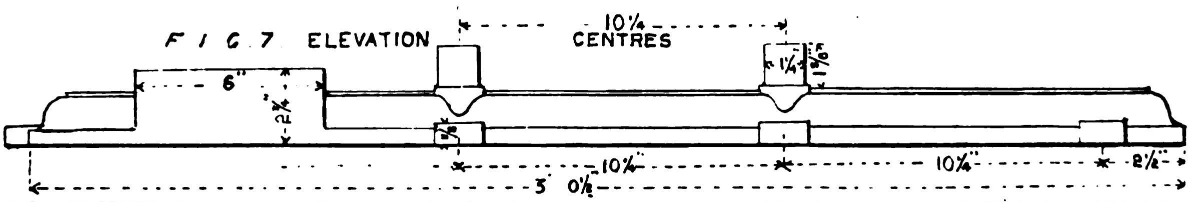
Again, the lugs for the hold-down bolts look somewhat out of proportion, and rather ungainly. But, while ¾in. hold-down bolts would be strong enough for an engine of six or eight times the power, we cannot have less than ⅝in. bolts in this, and, as the breaking off of a lug is an awkward thing, we give plenty of metal there, to avoid, if possible, that disaster.

As we go along, I shall not so much discuss the different ways in which our work may be done, as describe simply one method of doing it, guaranteeing, of course, that the patterns, if made to these instructions, will mould without causing any difficulty.

"Boxing-up," applicable to cored beds of a different section ("E. M.," Vol. XXXVII. p. 520), is not suitable in this case, where the inside of the pattern is wide enough to deliver itself freely. Nor, I apprehend, will it be necessary to give any rounding at all to the face, because, by thickening the metal at B, B (Fig. 8), we have counteracted the tendency of the plate to pull rounding when cooling. But with every precaution there is always some slight element of uncertainty associated with the "buckling," as it is called, of castings.

Now our way is cleared, and we can proceed accordingly. Looking at the bed in section (Fig. 8), we elect to have the flanged portion, C, C, made as a frame and fastened to the sides. Fig. 10 is intended to render the general construction clear. In the first place, then, we prepare two pieces (Figs. 8 and 10, B, B, B), 2ft. 9in. by $1\frac{3}{16}$in. by 1¼in., squared dimensions, and one piece 6½in. by $1\frac{3}{16}$in. by 1¼in. (which last piece, by the way, had better be worked in a length with one of the others, and cut off afterwards). One edge is planed $\frac{1}{16}$in. under square (for taper, Fig. 11), and the hollow of the ogee moulding is worked on the opposite edge. A mitre joint is cut at one end of each of the long pieces, and a similar joint at both ends of the short piece, which joints may then be glued and keyed, their further security being assisted by a few cross nails. Never trust to glued joints in moulders' patterns if nails or screws can be used. They are not like pieces of cabinet furniture, since in patterns mere appearance goes for little. Those who have seen patterns being "bedded in," or rapped, during withdrawal, will understand that this is not a needless caution. Let a couple of cross ribs (Fig. 10, *a*, *a*), ⅜in. thick, into rebated grooves, in positions indicated in Fig. 6, giving them also $\frac{1}{16}$in. of taper towards the back of the bed—*i.e.*, the face that lies on the foundation plate, and the uppermost face in moulding.

The semicircular end could be cut from one solid piece; but the chances are, in that case, that the pattern would become broken off accidentally



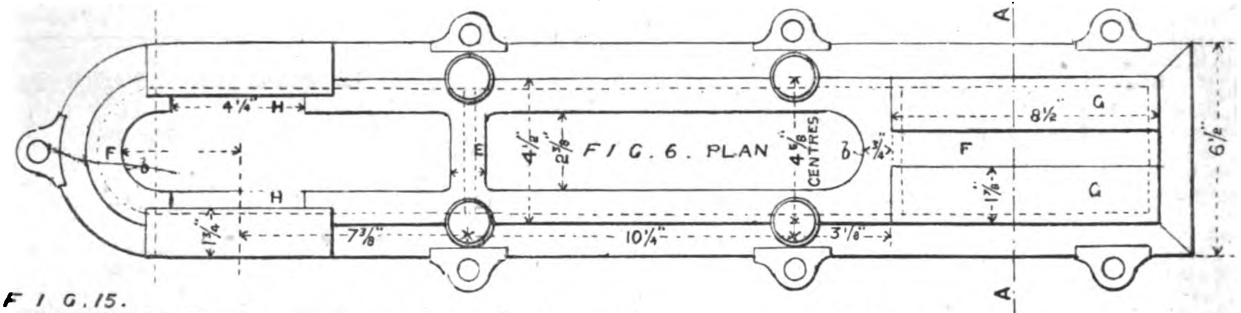


FIG. 15.

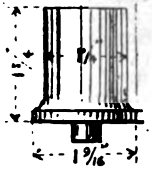
FIG. 14.



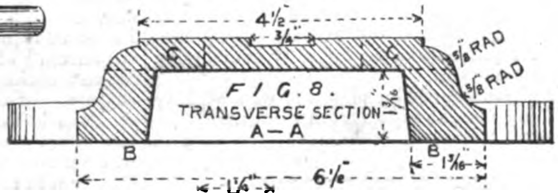


FIG. 9.

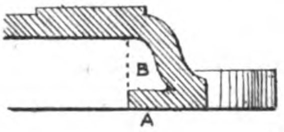

FIG. 11.

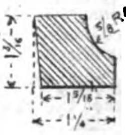

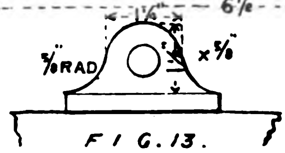

FIG. 13.

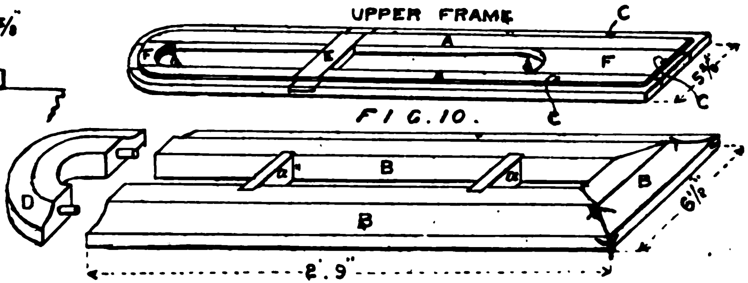

FIG. 10.

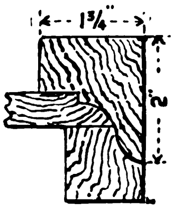

FIG. 17.

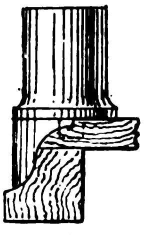

FIG. 17.

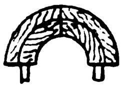

FIG. 12.

somewhere across the short grain. In a larger pattern we should glue this portion up in three or four rows of segments, as we should glue up a wheel ring (" E. M.," Vol. XXXVII. p. 143), but in this instance, two quarter circles glued together with a tight-fitting dowel (Fig. 12), will make a substantial job. The half-circle itself will be fastened against the ends of the straight pieces with tight-fitting dowels well glued (Fig 10, D). These should stand not less than ¾in. or 1in. away from the face. The lower frame is now complete.

For the upper frame we prepare two strips (Fig. 10, A, A), 2ft. 10½in. (2ft. 11in. in the rough) by 1⅜in. by $\frac{7}{16}$in.; fit in a cross bar, E, by half-lap jointing to dimensions (Fig. 6), and glue two ends, F. F, between, also to dimensions (Fig. 6), their grain running longitudinally. Strike the curves, *b. b*, with compass, set to 1$\frac{3}{16}$in. radius, and cut with paring gouge. Rebate back the square edge (Fig. 10, *c*, *c*, *c*, not exactly square, but slightly tapered upwards towards the face), representing the top fillet of the bedplate (Fig. 6 and 7), to 4½in., and downwards ⅛in.; then glue and brad this upper frame upon the lower one. When dry complete the convex portion of the ogee.

There is nothing rigid about this pattern; therefore when we fasten top and bottom frames together we shall assist it somewhat by glueing the frames together upon a " bottom board," that is, a piece of board planed up straight and in winding, or on a true bench, there allowing it to remain till set dry and hard. If it is allowed to set thus, it will not get out of truth afterwards, except by rough usage.

Prepare seven lugs, ⅜in. thick, 1¼in. by 1⅛in. (Fig. 13), striking the curves with compass set to ⅝in. radius. Slightly taper their edges in the direction of the face of the bed, and brad them on at centres given (Fig. 6). Narrow strips, ⅛in. thick, will form the filling-in to complete the thickness over the lower part of the moulding. Put a ¼in. round print upon each lug.

The four bosses for the guide bars will be turned to dimensions (Fig. 14) with a ⅜in. stud on the bottom, the grain running longitudinally. Note that the longitudinal dimension allows an ¼in. for facing. Besides this, give $\frac{1}{32}$in. taper in the length. Now when you come to mark the centres of these bosses, in positions shown in Fig. 6, you will find that the centre comes just by the edge of the fillet, and that some blocking is necessary; in fact, that the boss has to be continued over the ogee (Fig. 16). Why not have turned the bosses the entire depth and fitted them over, instead of using blocking-up pieces? is an idea that will suggest itself. Well, in practice it would take about twice as long, and would not be so neat a job—at least, in the hands of an unskilful workman, for the grain round the cut edges would become jagged, or "spalt" out, to use a workman's term. These blocking pieces will be got out, say 1in. longer than we require, and plenty wide and thick enough and fitted to the ogee. Chalk the moulding, and cut each blocking piece to a fit with a chisel and paring gouge. For the instruction of those of my readers who are not mechanics, let me mention that the paring gouge is a long gouge ground on its inner or hollow edge, instead of on its outer edge. These tools are used for paring the edges of long sweep for which a firmer gouge would be most unsuitable. They are made of various curves, termed respectively flat, middle flat, and quick, and of widths ranging from ¼in. to 1¼in. In length they measure about twice that of a firmer gouge. Fig. 15 gives a representation of one of these tools.

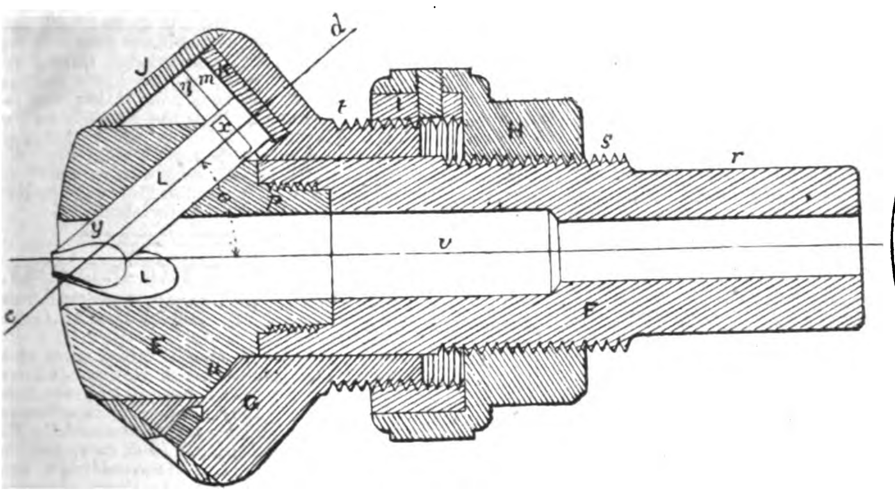
Well, having fitted each block in place, secure it temporarily with a ¾in. screw, and plane off its top face level with the face of the bed. Then bore in each boss centre a hole with a ⅜in. centre bit, for the reception of the pins of the turned bosses. Dropping these into place, mark their curve on the blocking pieces, remove the latter, work to shape, and replace permanently (Fig. 16). We shall not put prints on for the bolts of the guide bars, because these bolts must be tight fitting, which means drilled holes. Hence the bosses are complete.

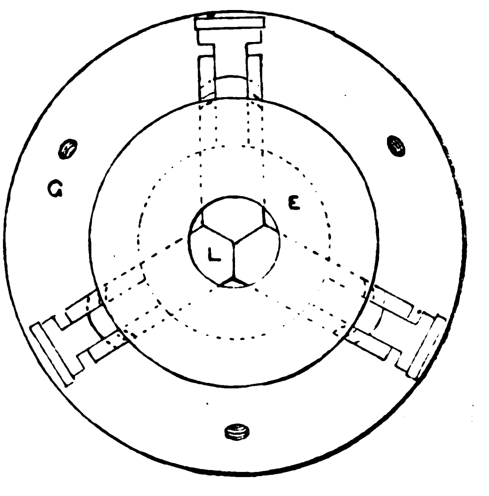
The two blocks for the crank-shaft bearings will be prepared to 6in. by 1¾in. by 2in. (this last allows for facing), and fitted with paring gouge and chisel over the moulding (Fig. 17), and fixed to centre given (Figs. 6 and 7). On the inner edges of these blocks a portion of the bed plate must be cut away to allow the crank to clear, Fig. 6, H, H. Two cylinder facings 8½in. by 1⅞in. by $\frac{1}{16}$in., fastened at G, G, Fig. 6 will complete the pattern.

Glass-paper smoothly, varnish with a coat of shellac varnish, and when dry, lightly rub down the grain which has become roughened, and apply a second coat. The pattern will then be ready for the foundry.

## BLUNT'S SELF-CENTRING CHUCK.

THE following is an illustrated description of a new self-centring chuck which has been recently patented by Mr. B. W. Blunt, of Nechells Park-road, Birmingham. The illustrations show the chuck in longitudinal section and the end with cover J removed:—Two round central parts, E and F, form the head and body of the chuck respectively. They are suitably attached to each other at P by being screwed together. Externally the end of F nearest to E forms a round guide, on which the block G is made to fit and slide. The other end of F forms a shank *r*, by which to attach the chuck to the machine in connection with which it is desired to be used. Between the guide and shank there is upon F an external screw S, which fits into a corresponding internal screw on the nut H. There is also a round hole *v*, which passes centrally through E and F to admit the article to be fixed in the chuck. Externally the cylindrical part of E of largest diameter, forms a guide upon which G is made to fit and slide. There is also a short cone, *u*, formed on the outside of E, through the surface of which three round holes pass obliquely into the centre hole and form guides for the three round clips L. Each of the three guides last mentioned is similarly situated in relation to either of the others, and also in relation to the central axis of the chuck, or so that each of the centre lines *c d* of the guides for the clips makes an equal angle with either of the others, and also an equal acute angle, O, with the central axis. The clips L are made to fit into and slide in the guides above mentioned. At one end, *y*, they are suitably formed to allow all of them at the same time to





approach the centre of the hole *v*, and to grip the article to be held by them. Near the other end of each clip there are two grooves, *x*, formed upon opposite sides of it, into which a suitable slide, *n*, on the block G is made to fit and slide, for the purpose of separating the clips. The block G has three sets of grooves on the front of it. In one of these grooves in each set a flat hardened steel plate K is fixed, to move in contact with the outer end of the clip and to cause it to move in towards the centre of the hole *v*. The other grooves, *m* and *n*, in each of the above sets form the slides which separate the slips. The sides of the plate K, which slide on the outer ends of the clips, are so situated that the centre line *c d* of the guides in E are perpendicular to them. Also each of the three sets of grooves in G already mentioned is similarly situated in relation to either of the others, and in relation to the central axis of the chuck. At its front end the block G fits into a conical cover J, the latter being attached to it by three small screws. There is an external screw *t* upon the back end of the block G, which engages with and fits into the nut I. Internally G has a central round hole passing lengthways through it, into which the head and body of the chuck fit. The cover J has a central round hole of the same diameter as that of the largest part of E. The nut H has a central round hole passing lengthways through it, in which there is an internal screw on the circumference of least diameter. This screw has preferably a left hand thread, which fits on the corresponding screw S on the body F. The other part of the central hole in H forms a recess into which the nut I fits and is rigidly fixed. Externally the end of H into which the nut I is fixed is round, and the other or smaller end is hexagonal. To actuate the chuck, the nuts H and I are turned round the axis by means of a spanner applied to the hexagonal part of H. The screw S causes the nuts to move bodily in a longitudinal direction according to the direction in which the nuts are made to revolve. Also according as the nuts move the screw *t* on the block G passes further out or enters further into the nut I respectively. Thus the block G moves along the axis in the same direction as the nuts H and I, but at an additional speed depending on the pitch of the screw *t*. When G is made to move in the left-hand direction, then the clips move towards the axis, and when the block G is made to move in the opposite direction, then the clips are separated further apart.

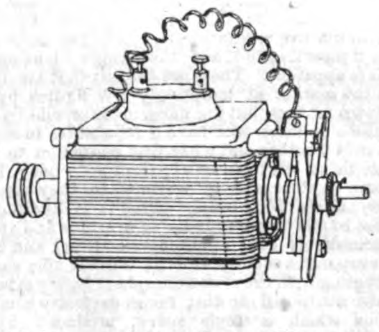
# ELECTRICAL MOTORS, AND THEIR CONSTRUCTION.—IV.

By John E. Chaster.

(*Continued from page* 315, *Vol. XL.*)

I MUST apologise for having kept so many readers waiting for this article; but business having called me away from time to time from town, I have completed the article at the earliest opportunity. I trust that few of the numerous readers interested in electrical matters have been inconvenienced.

The machine is now ready for wrapping with wire, and it should be taken in pieces, and whilst doing so it is advisable to carefully number or otherwise mark the parts that fit together, so that when finally put together no mistake may occur. Having got the motor in pieces, the field magnets are to be bound with canvas or calico, and well covered with either shellac or Brunswick black varnish, where the wire is to be wrapped on. The field magnets are to be wrapped with six or seven layers of No. 18 B.W.G. double cotton-covered wire. The exact amount got on will be determined by there being sufficient room for the armature to revolve when bolted up. About 1¼lb. of wire will be ample for the field magnets, and seven or eight ounces of 22 B.W.G. double cotton-covered for armature. When wrapping the machine it is by far the best plan to have a small detecting galvanometer and battery, such as a Leclanché, so that in case the insulated wire should at any part touch the iron of the field magnets the fault would be detected. This is effected by putting on the first bend of wire and joining the free end to the one terminal of the galvanometer, and from the other terminal of galvanometer take a wire to one binding screw of the battery, and from the remaining binding screw the wire comes that must be made fast and in good metallic connection with the iron of the field magnets. It will thus be seen that if the wire that is being wrapped on the field magnets should in any place make metallic connection with the field magnets, the galvanometer will, owing to the closing of the circuit, immediately be deflected. Should this occur, the wire must be taken off again until the leak be discovered when it should have a piece of calico, or, better still, fine linen, wrapped round the bared place on wire, and then remounted.



Secure all the ends of the wires either to the neighbouring coil or else by passing the finishing end beneath the adjoining layer and then drawing tight. All the three—viz., the two field magnets and armature, are ready to receive a coating on the insulated wire of thick shellac varnish. When dry, the machine may be finally mounted, and the ends of the field magnets so connected that the north pole of the one field magnet beds against the similar pole of the other field magnet.

When this has been ascertained, those two ends should be cut short so that there is left just enough wire to solder them together. This joint can then be insulated by binding round either cotton or tape, and carefully tucking same away so as to be out of sight as much as possible. One end of the field magnets is to be taken to one of the binding screws of the vulcanite (Fig. 22, p. 315, Vol. XL.), and the other end goes to one of the brushes of the commutator. The other commutator brush has a short length of copper wire to the remaining binding screw. The machine is now ready for trying to see how it runs. If carefully made it will revolve with a single bichromate, though to get its full efficiency it will be necessary to employ six or eight bichromate cells, each cell having a zinc surface of 3½in. wide and 6in. long immersed in the liquid. With a small boxwood pulley on the shaft, and about ¾in. to 1in. in diameter and ½in. in width. the machine is capable of driving a small lathe, fretsaw, and all light-running machinery.

Many persons have of late been writing against the Siemens H form of armature. For a dynamo from which a large amount of electrical energy is required, it does heat after a short time of running when made of large dimensions; but for small motors it is certainly the best considering all things, and is by far the easiest for amateurs to fit together; and if made of the very best carburetted annealed iron, it does not heat to an extent sufficient to do any damage to insulation of wire.

A suggestion was made by a Mr. Jones that I should use for my motor a clumsy imitation of the Siemens armature formed of strips of iron made in the shape of a cross. As I like to give everything a fair trial, I fitted one up in this style. When I placed this form of armature within the field magnets, I found the resulting power from the motor to be considerably less than with the Siemens H armature. This serious defect is attributable to the small amount of wire this cross form of armature holds compared with the Siemens H form. This cross form is more difficult to wrap than the ordinary Siemens, and requires more careful attention in connecting the ends of the wires to commutator.

After running it for a few hours, I found a considerable decrease of power, although the E.M.F. and current from batteries was the same as at starting. This suggested that the error must be in the armature itself.

On unwrapping the armature I found that the separate laminations of the cross form of armature had each set up a small counter rotary motion of its own, and had cut through the insulation of the cloth, and also that on the wire; so that the lower coil was short-circuited.

I trust that amateurs will be able to finish and complete the motor in a satisfactory manner, as it makes a motor of very high efficiency when correctly fitted up, and I should advise all amateurs to get the castings ready made, for making patterns of these is very troublesome, and beyond the capability of most amateurs. Mr. R. A. Lee, of 76, High Holborn, whose name must be well known to all readers, and who advertises in this journal, has made some very beautiful patterns of this motor (from my designs), the castings from which are everything that can be desired, well carburetted, thoroughly annealed, and so clean that I found there was scarcely any filing and turning required in fitting them up.

The engraving of the motor in this number is from a photograph taken from the finished machine, and will, in combination with the drawings previously given, make the general construction and fitting quite clear.

The motor being completed, requires a battery to drive same, and I propose therefore giving a few articles on the various forms of batteries suited for the purpose.

## DR. HUGGINS ON THE SOLAR CORONA.

In a lecture recently delivered by Dr. W. Huggins, F.R.S., before the Royal Institution, he gave an account of his experiments in photographing this rather puzzling phenomenon. In the course of the lecture, Dr. Huggins said:—Much of the light from the corona comes from near the ultra-violet end of the spectrum, therefore it might be expected to be seen through coloured media exercising the requisite selective absorption; but then comes in the drawback that the particular rays in which the corona is specially rich are near the limit of the power of the eye, and have but feeble influence upon vision. He therefore looked to photography for aid, especially as it is possible to accentuate photographic effects, so that the photograph is no longer true to nature. At first he tried experiments with interposed media, such as coloured glasses and layers of coloured solutions, including, for instance, potassic permanganate; but there were objections to this plan because of the reflections from the two surfaces, or from the decomposition of the chemicals by light having possibly the power of producing coronal-like images on the photographic plates. He next took advantage of the selective power for particular rays exercised by certain salts of silver. It has long been demonstrated that chloride of silver is particularly sensitive to the rays in which the corona is relatively rich, so that salt he concluded to be the best for his photographic operations. Then came in the difficulty about the imperfect achromatism of the lenses of refracting telescopes when used for photographic purposes; consequently he employed, in the first instance, a Newtonian reflecting telescope, with a large and a small mirror. In 1882 he thus obtained about twenty photographs, in all of which were forms very coronal in appearance, and critical observers, like Professor Stokes, Captain Abney, and others, thought that there was great reason to suppose that the coronal image had produced a specially visible effect on these plates. In his later experiments he used a telescope with a single mirror only, and the sun's light reached the mirror through a long tube, blackened inside, and containing many blackened diaphragms; he thus got rid of reflections from two mirrors. The backs of the photographic plates were covered with asphaltum, to prevent reflection from the back surfaces of the light which found its way through the photographic films; a circular black disc was placed in the telescope to cut off the image of the sun's disc entirely from the plate. With these precautions against obtaining erroneous coronal effects, what seemed to be true coronal impressions still came out on the plates. The conditions of climate being so unfavourable in England, it was thought well to repeat the trials in a better atmosphere, so the Royal Society appointed a committee and gave a grant for the execution of the work. The scene of operations was Switzerland, and the Riffel was chosen because of its height of about 8,000ft., combined with hotel accommodation. Mr. C. Ray Woods, who had had experience in astronomical photography during total eclipses in Egypt and in the Caroline Islands, did the actual work in a temporary hut on the Riffel, a photograph of which was projected on the screen by Dr. Huggins; it included a likeness of Mr. Woods, and represented the tube of the telescope bound round with flannel to prevent the heating of its exterior by the sun. For the last year or two, however, some fine matter had been in suspension high in the atmosphere of the earth, producing on fine days an aureole around the sun; this aureole was red outside, and violet inside; some thought it to be caused by spicules of ice, others supposed it to be due to vulcanic dust, but whatever it was, it was "matter in the wrong place" for the Swiss experiments of the Royal Society, so that the results were largely vitiated. There are five hypotheses to account for the corona: 1. That it is a large gaseous atmosphere around the sun. 2. That it is matter ejected from the sun. 3. That it is something of the nature of Saturn's rings, and consists of meteoric matter. 4. That we see the impouring of the tails of comets. 5. That there are meteoric streams illuminated by the sun, which are not revolving near the sun, or falling into it, but are parts of the elliptical orbits of comets. It would be safe to say that the corona is a complex phenomenon, and that there is probably some truth in all these hypotheses. An American professor has questioned the reality of the corona altogether, and suggested that it is but a diffraction phenomenon, but his theory rests upon negative evidence. He has against him the evidence given by the spectrum of the corona, and that photographs taken at different places show the same corona, which objection appears to be fatal to the non-coronal hypothesis. Without doubt there is a limited gaseous atmosphere around the sun, but this will not explain the corona. If there were but one particle of matter in every cubic mile, it would account for the corona, the particles being so close to the brilliant source of the light of the sun. There is gas with the particles, which may or may not be distilled out from them. The notion is gaining ground that there is a repulsive force connected with comets, not due to mass but to surface, therefore somewhat electrical in character, and it is possible that there may be some such force in the surroundings of the sun. If the existence of such force be granted, it may be that the corona consists of some of the blown-away matter of sun-storms; some part of the gas may have been carried up, or have afterwards been distilled from the solid particles by the heat of the sun; nothing is yet known of the condition of the gas between the particles. In the high vacua used by Mr. Crookes, the residual material particles represent a crowded city as compared with the coronal waste.

## DANGEROUS LUBRICANTS.

The following notes on the use of dangerous lubricants and false economy are contributed to an American oil-trade journal by Mr. E. F. Dieterichs:—

When we consider that lubricating means the interposing of substances between the parts in motion, to absorb the frictional heat and tranfer it into space by radiation, thereby avoiding abrasion and heating of the parts, we must see that only such lubricants will be able to accomplish the desired result which are entirely free from inert matter (grit), possess sufficient viscosity to secure adhesion to the metal and to be of such fire test as to secure radiation proportionate with the heat-absorbing quality of the lubricant. The injuries resulting from the use of poor lubricants will not always be perceptible at once, but they are produced gradually and persistently. The bearings of the machinery are tell-tales of the quality of lubricants used; they appear covered with gummy and dirty looking incrustations, the result of decomposed and accumulated impurities, and the saturated timber and floors in the vicinity of the bearings indicate the waste and danger resulting from the use of poor lubricants. Most of the cheap black lubricators are made from the residuum of petroleum stills, which to the best has been steamed and settled, thereby securing a less tarry colour and separating some of its gritty components, but much of the latter, most in the form of charred products, remain.

These residuums are thinned out to consistency for lubricating purposes, and as they are of very low gravity permit the use thereto of the cheapest kinds of natural oils, with their lighter and inflammable products, and frequently even the coarser kinds of benzine alone are used. These mixtures are brought to gravity of 28-29° B., in imitation of the once-celebrated 28° West Virginia oils, and are largely sold under that name to parties who look for a cheap oil and cannot determine its quality. Frequently these oils are mixed in so coarse a manner that when at rest the heavy residuum will separate in the packages, underneath the lighter fluid oil, and the danger of using such oils is apparent. These are the oils that are offered on the market at temptingly low figures by unknown makers, but are never made or sold by well-known refiners who have a reputation to sustain. In cold weather and when first poured on to bearings these oils have an apparent good body, but in warm weather and in warm places they soon thin out, and in flour mills, where it is distributed in close rooms over hundreds of bearings and spreads diminutively over adjoining woodwork and floors, it evaporates rapidly and its inflammable vapours mingling with the close atmosphere highly saturated with floating flour dust forms explosive combinations which a single spark, produced by the accidental getting in the mill of the smallest piece of iron, will explode. In saw mills, also, where pillar blocks, the surrounding woodwork, the floors and sawdust are saturated with such oils, and when on hot days and when the sun shines then the rising vapours can be seen, a flying spark from the rapidly revolving saws is all that is needed to set the whole place instantly on fire. What other explanation do we need when looking for the cause of mysterious explosions in flour mills, so assiduously attributed to the explosiveness of flour dust alone? Flour has been ground for generations in all climates and in all seasons, in airy places and in close and dingy ones, by hand and horse power, by wind and water power, and for a long time by steam power, and if the mills were not as gigantic as at present there was proportionately the same kind of work to perform, and when pushed to run day and night and with utmost strain on their machinery the chances for mysterious explosions were equal to the present time, but were never heard of. The danger from heated steps and bearings was well known, and many of the old hands cannot now be persuaded that anything other than lard or sperm oil is safe and fit to be used. Why, then, do managers of large mills and other establishments persist in running their machinery with poor and dangerous oils? They seem to forget that lubrication is as important a factor in the control and economy of motion and power as the need of hands to attend to it, as they need light to see at their work and fuel to produce the power and motion with which to do it; but inattention to these facts and false economy induce them to pursue a faulty policy. They claim it to be of no use to purchase better oil, as the hands pour it on recklessly any way, but acknowledge thereby poor management and want of control over their men. It is no wonder the men pour it on; they have to do it in order to keep the bearings cool, and while the oil runs out below as fast as they pour it on above, that makes them use it recklessly. With oil capable of doing its work with regularity they would not do so, as lubrication also means exertion; it requires attention and causes labour.

## HOW TO TREAT THE OILSTONE.

The following remarks are extracted from a paper by J. F. Hobart in the *American Machinist*:—

Keep your oilstone clean. Many users of oilstones keep them full of oil all the time, all covered with dirt and gudgeon-grease, and when they want to use them, must scrape a place with a chip before they can make a tool "take hold." Wipe the stone clean after using. Do it every time, too, not once in a while. Get in the habit of it, and it will come natural. Don't let a stone get gummed up. If you have been guilty of keeping such a one, just take a new deal and "try out" your stone. Put it in a kettle with water and potash, and set it over a fire, or stick a steam pipe into it. Boil for an hour or two, then soak and wash well in clean water. You will then be able to see what your oilstone looks like, and it will "take hold" like a new broom. Some men place their oilstones in the sun and let the oil dry out. But the potash is the best; it "kills" the grease on the spot. An oilstone needs "truing up" very often. Don't let a stone get too "hollowing." Use long strokes in rubbing a tool upon it. If it gets a little worn in the centre, take it to the grindstone or a big emery wheel. Hold it against the side of the wheel, not on the face. It will take but a very few minutes to grind the oilstone true and smooth. I never yet saw a loafer hang around a shop half-an-hour without getting out his jack-knife and "going for it," upon the middle of an oilstone. If I have a knife to sharpen, I do it near the end of the stone. The ends don't wear down; it is the middle that gets most of the work. Some journeymen put a wire across the middle of their oilstone. They have to work each side of it, but the loafers have to too.

If you break a stone, don't throw it away. If thick, or nearly new, boil the grease out of it, and glue it together with common glue. It will hold if you get all the grease boiled out before you put on the glue. If the stone has become worn pretty thin, you had better grind it down into slips. It will make some nice ones of the very best quality. Don't put the stone into a block of wood. It makes a nasty thing to keep clean; go to the hardware store and buy a nice oilstone holder. You can put it on in two minutes, and take it off in "no time," and wipe the stone clean as often as you wish. A hard, glossy oilstone is not worth buying. A stone which looks like a piece of marble is good for nothing. A stone with a sandstone complexion is too soft, and will work bad. The "muddy" stone is another to be avoided. Somewhere I have seen a receipt as follows: "Draw your thumb nail along the stone; the faster it cuts away the nail the better the stone." It looks reasonable, but I have never tried it.

Petrified wood makes the best oilstone. I have a Scotch stone which cuts very fast, yet will set an edge to "cut a hair." Some years ago a firm started to manufacture "silex" stones for oil and water, both hand and power. The "silex" stone was ground fine, mixed with some secret "uniting compound," and moulded under hydraulic pressure. The stones thus produced were pretty good, but were apt to "glaze," and then neither oil nor water seemed to have any effect in removing it. Whether or not they are made now, I do not know. There is a knack in using oilstones well. Don't rock your hand and make six or eight bevels on the work, or else make a curve in place of a flat "bevel." Keep your wits upon the top of the tool, and see that it travels as fast as the bottom edge does. The tendency, when pushing from you, is to lower the top of the tool, but a little attention to this point will enable a man to do a job right, and get a better edge in the very shortest time.

**Test of Cod-Liver Oil.**—Pour about ten minims of the oil to be examined into a watch glass. Dip a pointed glass rod into concentrated sulphuric acid, and with the moistened point mark as if writing or drawing on the bottom of the glass, through the oil. Wherever the point goes it will be followed, if the oil is pure, by magnificent streaks of a pure violet colour. The reaction is equally beautiful, if the oil is first cut with or dissolved in carbon sulphide, as prescribed in the German Pharmacopœia If the point of the rod is passed lightly over the surface of the oil, just touching it, the violet streamers may be watched descending little by little until they reach the bottom.

# SCIENTIFIC SOCIETIES.

## LIVERPOOL SCIENCE STUDENTS' ASSOCIATION.

THE fifth evening meeting of the current session of this association took place on Friday, Feb. 19th, in the Common Hall, Hackinsbey, the president, Mr. Norman Tate, in the chair.

The paper of the evening, on "Mineral Crystals," was read by Mr. Charles E. Miles, who, in the course of his address said: Hidden from sight of men in the bosom of the earth lie great treasures of form and colour known as mineral crystals. From their symmetrical outlines and rich appearance, they have not inaptly been termed the flowers of the mineral kingdom. It is strange that with all their attractive features, and notwithstanding the general march of science of late years, comparatively little more is known about the laws which govern the formation of crystals than what was known some sixty years ago. Crystals may be looked upon as the most perfect form which inanimate matter assumes, and when perfectly developed they form complete geometrical figures. However much crystals may be complicated in form, they all can be referred to one of six distinct plans or systems of crystallisation. Not only have crystals symmetrical outlines, but law and order control them completely. Even in a seemingly confused mass of crystals we can notice that a definite plan fixes their arrangement one with another. We have some evidence of the molecular structure of crystals by their action upon light. It is found that each system of crystals possesses its own peculiar action upon light in its passage through them, interfering with its passage differently. Some crystals, on being excited, exhibit peculiar electrical properties. So far the electrical condition has been little understood, but it may yet be found that these electrical conditions set up under the process of crystallisation have much to do with the manner in which minerals are found crystallised or associated together in the earth's crust. Of late years much advance has been made in the science of petrology, or the study of rocks, simply owing to the knowledge obtained of the optical characters of mineral crystals under the microscope, the practical outcome being a knowledge of the mineral structure of many rocks, which by ordinary chemical analysis could not be obtained.

## CHEMICAL SOCIETY.

THE following among other papers were read at recent meetings of the above Society:—

"On the Atomic Weight of Titanium." By Prof. T. E. Thorpe, F.R.S. The atomic weight of this element was made the subject of investigation so far back as 1823 by Heinrich Rose. In 1829 Rose published a second series of determinations, which were followed in 1847 by the determinations of Pierre, and in 1849 by those of Demoly. These determinations have given values for Ti varying from 47·92—56·39. In framing his arrangement of the elements in accordance with the Periodic Law, Mendelejeff adopted the number 48 as the atomic weight of titanium. A number less, than 50 was in fact demanded by the law. A redetermination of the atomic weight of this element, therefore, was obviously required, not only to fix its value as a chemical constant, but as affording an excellent test of the validity of Mendelejeff's hypothesis. The exact determination of the atomic weight of titanium is rendered difficult from the circumstance that comparatively few compounds of this element exist which are wholly suitable for the purpose. The author of the present communication has made use of the tetrachloride and tetrabromide as the bases of his experiments. He has determined the amounts of chlorine and bromine in these compounds, and also the amounts of titanic oxide which they yield by decomposition with water. The mean of the whole 31 experiments becomes 48·013, the probable error of the series being ± 0·021, and the probable error of the result ± 0·0085.

"On the Physiological Action of Brucine and of Bromostrychnine." By Dr. T. Lauder Brunton, F.R.S. The difference between the effect of brucine and strychnine appears rather to be one of degree than of kind, and to be chiefly dependent on the more ready elimination of brucine. Like strychnine, brucine produces death by convulsions and not by paralysis; but like curare, it is innocuous *when taken* into the stomach, though fatal when *injected* under the skin. Bromostrychnine has an action very much like that of strychnine.

A lecture "On Chemical Changes in their relation to Micro-Organisms," was delivered by Professor Frankland, D.C.L., LL.D., F.R.S. A plant being defined as an organism performing synthetical functions, or one in which these functions are greatly predominant; an animal as an organism performing analytical functions, or one in which these functions greatly predominate: the micro-organisms were classed by the lecturer among animals. Their life essentially depends upon the taking asunder of more or less complex compounds, resolving them into simpler compounds at the expense of potential energy. As micro-organisms are commonly termed "ferments," and their analytical operations "fermentations," it is necessary to sharply distinguish between organised ferments and certain bodies which bring about analogous chemical changes, but which are not only not organised, but exist in solution. These latter, or "soluble ferments," as they are commonly termed, are said to act by contact; they produce certain chemical changes in the fermentescible substances without themselves furnishing from their own substance any of the products of change; the effects they produce are essentially analytical, consisting in the assimilation of water and the splitting up of the fermentescible substance into two or more new molecules, and may be brought about by purely chemical means. They differ only, or chiefly, from the organised ferments in that they are unorganised and do not increase in amount during their action upon fermentescible substances, of which a very large, although limited, quantity may undergo transformation by the action of a very minute quantity of the ferment. A list of changes brought about by unorganised ferments was given. In that portion of the animal kingdom with which we are best acquainted, oxidation is the essential condition of life; it is the kind of action by which the animal changes actual into potential energy. The changes effected by micro-organisms are essentially of the same character as those brought about by the higher orders of animals—that is to say, they are all changes by which potential becomes actual energy. With one or two exceptions, the chemical changes effected by micro-organisms—unlike those produced by soluble ferments—cannot be brought about by other means. The observations of Hutton and others have shown that micro-organisms retain their vitality in presence of a variety of substances which rapidly prove fatal to higher animals; the unexpected fatal effects of spongy iron would seem to promise, however, that there are substances fatal to bacterial life which have no toxic effect on more highly organised animals. It has not yet been shown that any degree of cold, however intense, is fatal; animation may be suspended, but it is restored when the temperature rises. With regard to heat, the lowest fatal temperature recorded is 40° C., but many species can withstand much higher temperatures. Chloroform and compressed air are said to arrest their action, but to have no influence in preventing the changes brought about by unorganised ferments. The position of micro-organisms in nature is only just beginning to be appreciated; their study both from chemical and biological points of view is, however, of the highest importance to the welfare of mankind, and leads the inquirer right into those functions of life which are still shrouded in obscurity. In the course of the lecture the best known micro-organisms and the chemical reactions due to them were passed in brief review.

**All Made from Smoke.**—The old saying that nothing is wasted or lost in nature is true in regard to the smoke from the furnace of Elk Rapids, Mich. In this furnace are manufactured 50 tons of charcoal per day. There are 25 charcoal pits, constructed of brick. Each pit is filled with 100 cords of hard wood and then fired. The vast amount of smoke from these pits, which was formerly lost in the air, is now utilised. Works have been invented to convert the smoke into chemicals and acids. These works are a curiosity. First, they have a circular tube made of wood, with pine staves, 16ft. in length, bound together with heavy iron hoops. This tube is placed directly over the pit in a horizontal position, with an opening from each pit into the tube. At the end nearest the building there is a large drum containing a rotary pan propelled by machinery, the power of which is gas. That acts as a suction or draught for the smoke, which is conveyed into fire-stills with copper pipes 2½in. in diameter. The boxes in which the pipes are situated are 20ft. square, 8ft. deep, made from heavy pine, and filled with cold water; they are all connected by copper pipes. They are connected with the main still, 100ft. in length, 10ft. wide, and 8ft. deep, filled with copper pipes 2½in. in diameter, in horizontal position, surrounded by cold water; from this it is conveyed to the purifier, from which runs what is called pyroligneous acid, which is as clear as amber, with an unpleasant odour. From the acid is produced, first, acetate of lime; second, alcohol; third, tar; fourth, gas, which is consumed under the boiler. Each cord of wood contains 28,000 cubic feet of smoke; 2,800,000 feet of smoke handled every 24 hours produces 12,000lb. of acetate of lime, 200 gallons of alcohol, and 25 pounds of tar. These products have a commercial value in the manufacture of various articles. The smoke from 40,000 cords of wood consumed per annum is thus made a source of much profit, as the works are automatic and require no workmen to run them.

# SCIENTIFIC NEWS.

ACCORDING to Prof. Backlund's elements. Encke's comet should make its nearest approach to the sun on the 7th inst., and its nearest to the earth three days later. M. Bigourdan describes it, as observed at Paris last month, as a brilliant nebulosity about 2′ in diameter, with a bright centre shading off gradually. There was a small nucleus a little *n.f.* the centre, but no tail.

On the 7th inst. the position of Wolf's comet will be R.A. 3h. 18m. 42s., N. Dec. 0° 18·2′ at 6h. G.M.T.

The *Proceedings* of the Royal Irish Academy for July, 1884, contains a catalogue of known variable stars, with notes and observations, by J. E. Gore, F.R.A.S. It occupies 62 pages, and will be useful to those who are interested in variable stars.

The death is announced of Prof. T. C. Archer, the director of the Edinburgh Museum of Science and Art, at the age of sixty-nine.

Mr. John Francis Campbell, of Islay, died recently at Cannes at the age of sixty-four. He published a few months ago a work on thermography, and was the inventor of the Kew sunshine-recorder, but he is more widely known by his collection of the folk-lore of the Western Highlands.

The death is also announced of Hofrath Schmid, professor of mineralogy at Jena.

At the annual meeting of the Paris Academy of Sciences, amongst the prizes awarded we note that the Monthyon was apportioned to M. Riggenbach, the Swiss engineer, for his railways in mountainous districts; the Lalande for astronomy to M. Radau, for a memoir on refraction; the Poncelet, for progress in mathematics, to M. Houel; the Salz, for astronomy, to M. Gurzel for a memoir on ancient eclipses, in order to determine the value of the secular acceleration of the motion of the moon; the Tremont prize was awarded to M. de Taste, for his works on meteorology; and M. Marsault was awarded 1,500 francs for his studies on miners' safety-lamps.

The National Fish Culture Association is endeavouring to put the propagation of fresh-water fish on a more extended basis, and for that purpose is erecting a large establishment at Dalaford Park, Bucks, near the River Colne, for breeding various species of salmon, trout, and other fish, including the German carp, which is superior to the English species, both in rapidity of growth and as an article of diet. The site is well chosen, and anglers throughout the country may have cause to thank the association for its efforts. The association also purposes carrying out a scheme for obtaining records of the temperatures of the sea at several parts round the coast in order to gain knowledge which will be valuable in its endeavours to promote the propagation of sea fish.

Mr. S. F. Baird, the United States fish commissioner, is helping in the work of pisciculture in this country, and has already forwarded to South Kensington a large consignment of ova of the more highly-prized American fishes.

The use of the electric launch as a police boat on the River Thames and elsewhere is likely to prove a success, for, compared to a steam launch, its movements are noiseless, and the same power that is employed to propel it can be utilised for supplying current to an arc lamp for "searching" purposes. The launch with which the experiments have been made is 25ft. long, with a beam of 5ft. 6in., and carries 50 accumulators, each weighing 40lb. It can maintain a speed of eight miles an hour for four hours; but can be made to travel faster on emergency. The search lamp is of 3,000 candle-power, and, as the term implies, the beam can be sent in nearly every direction.

Mr. J. Roach, who is constructing several vessels for the United States Government, has received orders to use iron for all shafts, as steel is not considered trustworthy. It is said that of the iron shafts Mr. Roach has put into steamers none have broken, but the number of steamers is not stated.

A company has been started in New York, with a capital of £40,000, to build "navigable trains of air-ships," in accordance with the designs of an inventor who has already seventy-eight patents in connection with aëronautics, and is about to present some 250 more improvements to the Patent Office. The principal novelty in the idea is the making up of a "train" of air-vessels, each consisting of a balloon circular in perpendicular section, held together by means of cables passing through the cars. Each portion of the "train" is provided with screw propellers and rudders, by means of which it is conceived that it will be possible to ascend and descend without interfering with the gas in the balloon or the ballast in the cars.

According to an American paper, the two Fontaine locomotives, which cost about 45,000 dollars, including the expenses of their trials, were sold lately to the Lake Erie and Western Railroad for 2,700 dollars. One of the engines is said to have run 15 miles in 10 minutes on one occasion.

MM. Jeannolle et Cie. recently forwarded an account of their experiments with electricity as an anti-incrustater to a manufacturers' meeting at Calais. By passing a current through a boiler, they not only caused the impurities in the water to settle in a pulverulent condition, but loosened the old incrustation.

Cremation is making progress in Paris, and Prof. Brouardel, who was charged by the Council of Hygiene to report on the matter, proposes to establish a crematorium in Père la Chaise as an experiment.

Mr. E. T. Hardman, who was sent out to Western Australia to explore the Kimberley district, reports a discovery of the gigantic extinct Kangaroe, *Diprotodon Australis*, which is an interesting addition to Australian palæontology.

With a view of keeping some record of the action of the Whitworth scholarships and of ascertaining how the endowment fulfils the intention of the founder, the Science and Art Department of South Kensington has issued a circular asking those who have held scholarships to state in what profession or occupation they have been employed since the expiration of their scholarship.

## USEFUL AND SCIENTIFIC NOTES.

**Screws, Bolts, and Nuts.**—Mr. Morris Cohen, of Kirkgate, Leeds, sends us an illustrated price list of screws, bolts, and nuts for clock, model, and mechanical work. The illustrations show the actual size of the screws, &c., but their dimensions are also given in the priced list, which should be very useful to amateurs and others. We understand this is the first list of the kind ever published.

**Asaron.**—The essential oil of *Asarum Europæum* contains 1 per cent. of an odourless kind of camphor —asaron $C_8H_{10}O_2$—which is possessed of remarkable phosphorescent properties, and admits of distillation in small quantities without undergoing decomposition; it is slightly soluble in boiling, but readily so in alcohol, ether, chloroform, and petroleum ether.

Sympathetic ink for writing on postal cards, the *Paper World* says, is made of diluted sulphuric acid, one part by measure of acid to seven of water. When this ink is used the card will at first show roughened traces of the writing, but after being allowed to dry for a short time these disappear, and it is as invisible as if done with water. Of course, only a gold pen or a quill must be used. If it is desired to avoid the suspicion of using sympathetic ink, it may be written upon, across the first writing, with tincture of iodine, which will entirely fade out when the heat is applied to develop the invisible ink.

According to the annual statistical report of the secretary of the British Iron Trade Association, the home production of iron ores in 1884 was considerably less than in 1883, as is evident by the diminished production of pig iron; but to what extent the output was reduced there are no official figures yet available to show. In the Cleveland district, however, the total output of iron ore has been ascertained by the Cleveland Mineowners' Association to have been 6,005,000 tons, against 6,700,000 tons in 1883, and 6,326,000 tons in 1882. The output of 1884 therefore showed a decrease of 695,000 tons on 1883, and of 321,000 tons on 1882.

In Norway and Sweden accumulations of moss, often more than a foot thick, and half decomposed, serve to make paper and millboard, as hard as wood, blocks of which, formed by the hydraulic press, may even be turned in the lathe and polished. This substance is said to possess the good qualities of wood without the defects, such as warping and splitting, so that it is suitable for making doors and windows. Plant has, it is said, been laid down in Sweden for working up these deposits of a hitherto waste substance into a useful material.

# LETTERS TO THE EDITOR.

*[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.]*

*All communications should be addressed to the* Editor *of the* English Mechanic, *332, Strand, W.C.*

*All Cheques and Post-office Orders to be made payable to* J. Passmore Edwards.

*⁂ In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

> "I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks a vice from whence great inconveniences derive their original."
> —*Montaigne's Essays.*

## THE SOLAR ECLIPSE ON MARCH 16, 1885.

[23888.]—It is very desirable that amateur astronomers should not always lose sight of the fact that the words "invisible at Greenwich," which appears in our national ephemeris in reference to certain solar eclipses, do not always imply that such phenomena are entirely excluded from the gaze of all the inhabitants of Great Britain and Ireland. We have a case in point in the eclipse of Monday, March 16. A glance at the diagram, which is inserted at page 396 of the *Nautical Almanac* shows that the course of the central line on this occasion traverses the continent of North America; and although it is not total, but only annular, it seems to be exciting a good deal of interest among the astronomers there, and no doubt the times of commencement and ending, and the angles, which the points of first and last contact, when joined with the centre of the sun's disc, involve with reference to the Vertex and North Point, will be very eagerly scanned. But although in these islands we are not permitted to enjoy much of this spectacle, there is one station at least where scientific men are to be found at which the phenomenon will be unique and striking, and it is to be hoped that amongst the staff of persons employed in connection with the Atlantic telegraph and the Meteorological Department, some one will be found to describe what is to be seen, if the weather proves favourable, on the evening referred to. At Valencia the commencement of this eclipse is visible shortly before sunset—viz., at 5h. 40m. local mean time, and the middle of the eclipse happens at 6h. 34m., soon after the sun has descended below the horizon at 6h. 4m. The appearance of the sun as it dips beneath the sea will be sufficiently remarkable—a large semicircular incision being made in the disc on the right-hand side, commencing along a line parallel to the horizon, and cutting its globe almost perpendicularly at the time of sunset.

For the sake of such of your readers as may choose to verify these statements by a computation made on the partially-graphic method, I will add the elements of the calculation and a miniature diagram showing the result. It must be remembered that the actual projection requires a half-sheet of demy, and an ellipse of which the semi-major axis is 10in. See Vol. XXVI. p. 408.

Elements.—I. Lat. 51° 42′ 52″ N. Geoc. Long. 0h. 41m. 40sec. W.

Cos. $\delta$ = 9·99986

1·64950

P $\rho$ sin. $l$ cos. $\delta$ = 44·62′ +

Difference = 48·01

Moon above parallel = 3·39′.

Value of 10 divs. of Lat. Par. Scale = 2·838 in.

IV.

X cos. D = 29·23′

X = 9·36 ascending.

Moon above parallel = 3·39 +

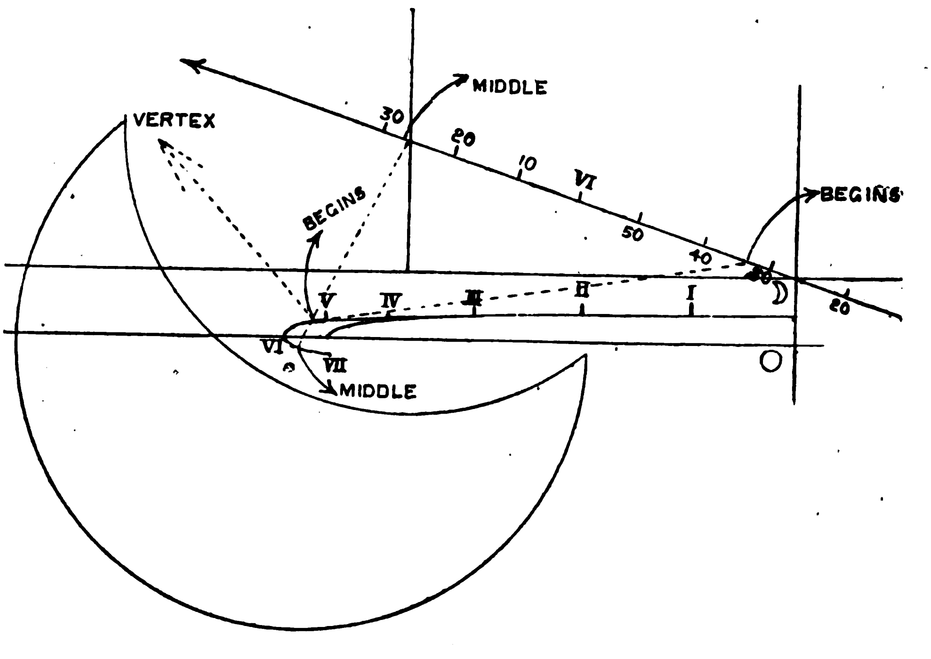
Moon's ½ diam. = 15·6

Sun's = 16·1

The foregoing elements are quite sufficient to furnish the construction of the requisite diagram, of which the following is a miniature.

James Pearson, M.A., F.R.A.S.

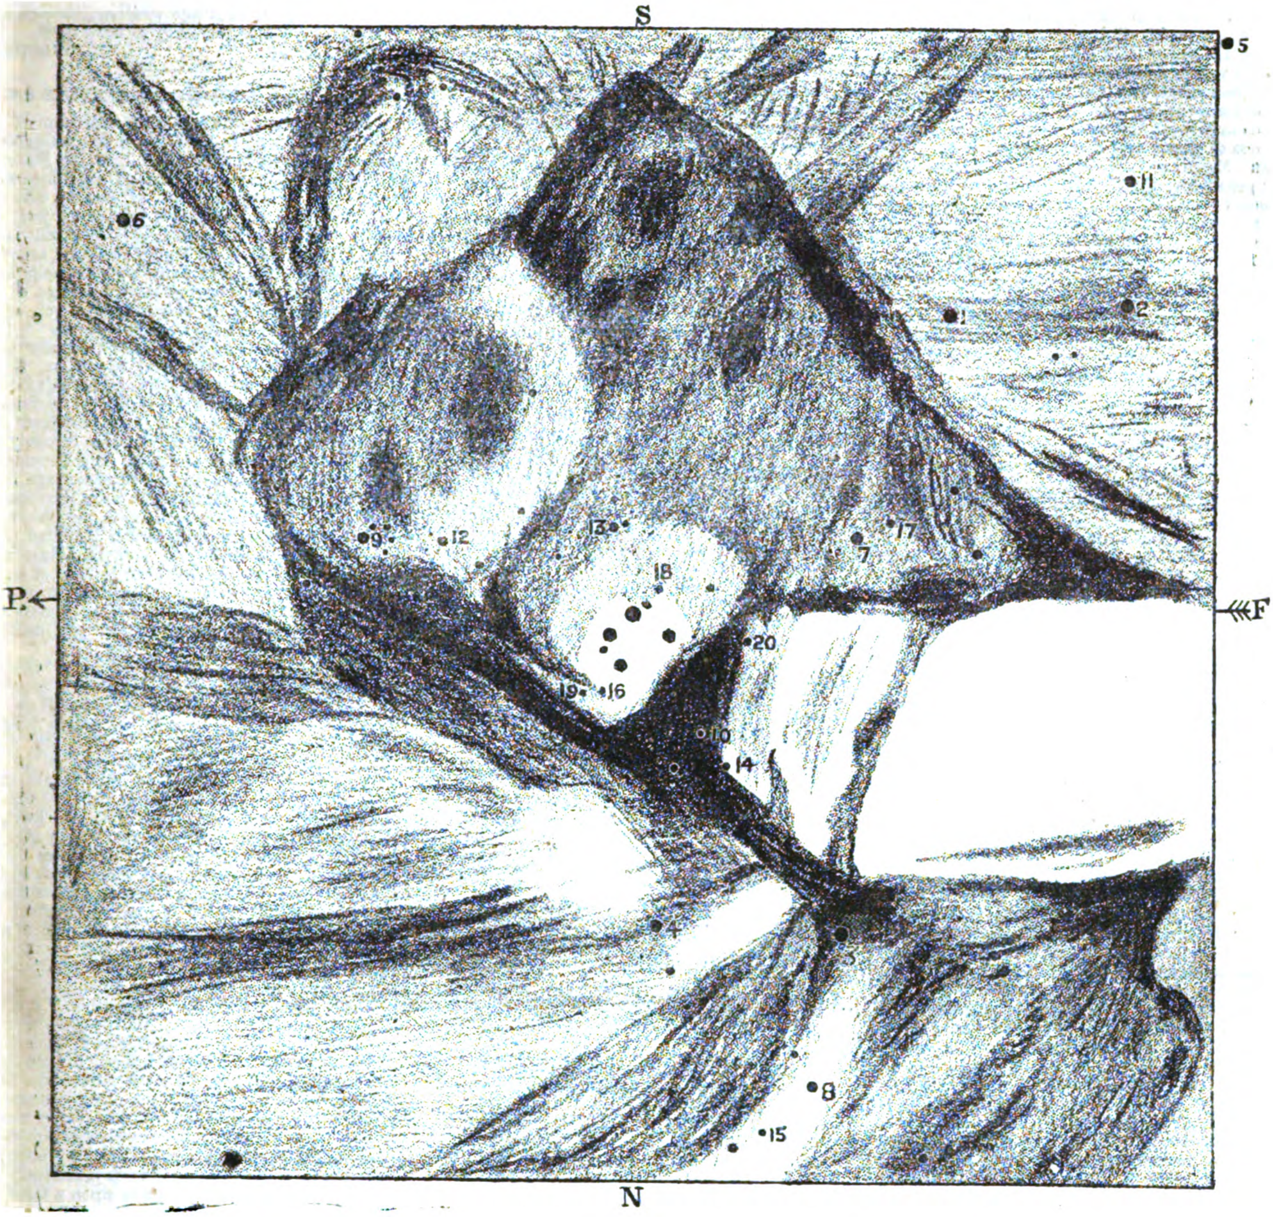
Fleetwood Vicarage, Feb. 23, 1885.



## THE OCCULTATION OF ALDEBARAN.

[23889.]—I have received two communications in reference to the above phenomenon, both of which, I am happy to say, indicate the success with which the partially-graphic process of computation, which I have recently devised, and which is described in Vol. XXXVI. p. 405, and Vol. XXVII. p. 10, of the English Mechanic, may be applied to practical purposes. The only merit I claim for it is its brevity and accuracy. It accomplishes in three-quarters of an hour a calculation which, by the methods of Woolhouse or of Shadwell, would require a host of figures and a very large expenditure of time. And this it does on a half-sheet of note-paper and a half-sheet of demy.

The first communication is from Prof. Smyth, of Edinburgh, who states in a letter to the *Scotsman* newspaper of Feb. 23, "The interval between the two signals turned out to be, by the assistant's notation on the chronometer, not more than two seconds and 6-tenths; but the difference of either from the Rev. James Pearson's calculation was an affair of minutes—until the already ascertained



error of the chronometer was applied, and then the absolute time of the first signal was found to be 5h. 4m. 58·2sec., and of the second 5h. 5m. 0·8sec.; while the time computed by Mr. Pearson was 5h. 4m. 58sec. In so far, then, a signal success." A cumulus cloud prevented all further observation.

The second communication is from an observer in Belfast, who writes: "Occultation of Aldebaran well observed. True local time 5h. 29m. 40sec. Long. 0h. 23m. 40sec. W.; Lat., 54 deg. 36m. N. Telescope employed, 4¼ refractor; power, 74. Definition very good. Local time correct to five seconds." A computation made on these data by the partially-graphic process gives the time of ending 5h. 29m. 40sec., which, considering all the circumstances, may be pronounced to be an equally exact prediction with the former.

**James Pearson, M.A., F.R.A.S.**

Fleetwood, Feb. 23, 1885.

## STARS NEAR THETA ORIONIS.

[23890.]—The annexed sketch of part of the central portion of the Great Nebula in Orion, showing the general features of the nebula itself, and the positions of the stars inclosed in it, may be of use to those of your readers who may be desirous of looking for other faint stars besides the fifth and sixth in the Trapezium with small apertures. The sketch shows all the stars in Bond's catalogue within 180″ *p.* and *f.*, and the same distances north and south of the brightest star in the Trapezium ($\theta'$ Orionis of Flamsteed, C of Σ 748, 628 of Bond's catalogue), and most of the stars seen at Malta, Parsonstown, and Washington. All Bond's stars are laid down from the co-ordinates given in his work, and the nebula has been sketched in from the drawings of Lamont, Bond, d'Arrest, &c. The delineation given here does not pretend to any great degree of accuracy, but will be sufficient for purposes of identification. In order to prevent confusion, I have not attached reference numbers to any of the six stars of the Trapezium, or to any below the 13·5 mag. in Argelander's scale—a magnitude which may be taken to be about the *minimum visibile* in a refractor of 7in. or 7½in. aperture.

The reference numbers, arranged in order of magnitude, Bond's Nos., the magnitudes in Argelander's scale, and the co-ordinates $\triangle\alpha$ and $\triangle\delta$ in seconds of arc, reckoned from $\theta'$ Orionis as the origin, are as follows:—

| | | | Co-ordinates. | |
|---|---|---|---|---|
| | Bond's No. | Mag. | $\triangle\alpha$ ″ | $\triangle\alpha$ ″ |
| 1. | 685 | 7·7 | + 96·9; | − 95·8 |
| 2. | 708 | 8·5 | + 150·6; | − 99·5 |
| 3. | 669 | 9·8 | + 62·9; | − 99·2 |
| 4. | 635 | 10·5 | + 7·9; | − 97·7 |
| 5. | 724 | 10·5 | + 182·3; | − 177·0 |
| 6. | 558 | 10·7 | − 159·7; | − 119·0 |
| 7. | 671 | 11·5 | + 69·0; | − 25·2 |
| 8. | 663 | 11·7 | + 55·1; | + 146·3 |
| 9. | 575 | 11·9 | − 85·4; | − 22·7 |
| 10. | 647 | 12·1 | + 22·0; | + 37·4 |
| 11. | 709 | 12·3 | + 152·1; | − 137·4 |
| 12. | 589 | 12·7 | − 57·8; | − 21·0 |
| 13. | 622 | 12·7 | − 8·1; | − 28·4 |
| 14. | 651 | 13·1 | + 28·8; | + 47·0 |
| 15. | 657 | 13·1 | + 39·4; | + 164·4 |
| 16. | 618 | 13·1 | − 11·0; | + 24·0 |
| 17. | 676 | 13·1 | + 77·9; | − 28·4 |
| 18. | 636 | 13·3 | + 7·8; | − 9·3 |
| 19. | 612 | 13·5 | − 17·0; | + 24·0 |
| 20. | 654 | var. | + 32·6; | + 9·2 |

The magnitudes of Nos. 1 and 2 are taken from Prof. Safford's table on p. 123, as they appear preferable to those given on p. 85. No. 18 has been called the seventh star of the Trapezium, its position from C. of Σ. (*cf.* English Mechanic, Vol. XXXIV. p. 448) being about 136° 12·1″. O. Σ. failed to see it at Pulkova with the 15in. refractor, as also Nos. 19, 16, and 13. No. 20 is the celebrated variable, No. 78 of Sir J. Herschel's catalogue in the Cape observations. It varies from about 11·5 mag. to invisibility, and the change is very rapid. Several others have been also thought variable.

Those observers who see, or imagine, faint stars inside the Trapezium should determine the limit of visibility with their telescopes on such occasions by means of the stars shown on this chart. Prof. Holden found that 11·0 mag. Arg. was about the limit of visibility with the central 3·5in. of the 26in. refractor, and a power of 175, in January, 1878; with a power of 400, he fancied he saw the fifth and sixth at intervals, knowing exactly where to look for them.

In letter 23842, page 539, for 633 ‖ read 633**. In the table on page 8 of Prof. Holden's monograph of Σ. 748, for 617 read 617 ‖, and delete the two asterisks attached to No. 640.

Feb. 21. **H. Sadler.**

## DRAWINGS OF THETA ORIONIS.

[23891.]—No doubt Mr. Binns (letter 23867, p. 557) will pardon me if I direct his attention to the fact that I never asserted that *he* had said anything about the moon in reference to his observation of October 4th, 1882. According to the almanac, the moon was at that time about 30° N.N.E of $\theta$ Orionis, and ought, as she was at her last quarter, to have been shining "brilliantly," and I fail to see how my statement to that effect was in any way erroneous. Possibly the behaviour of the moon, as seen from your correspondent's residence on the morning in question, may have been as eccentric as that of the satellites of Jupiter on a previous occasion, duly reported by him on page 99 of Volume XXXIX; but that is Mr. Binns' business, not mine.

As Mr. Binns seems to be still under the pleasing delusion that his drawing could represent the appearance of the Trapezium, relatively to the cardinal points, as he has shown them, in a direct or any other eyepiece, or in any conceivable hour angle, it would be cruel to attempt to disabuse him.

After reading letter 23843, however, I would venture to suggest, with all due defererence to him as an "Assoc. M.I.C.E.," that the next time he favours us with a drawing of some celestial object it should be executed in ink, and not in pencil, and that if he happens to describe a circle, or a few stars too many in his first attempts, he should take a fresh piece of paper and commence *de novo*. The ENGLISH MECHANIC is a scientific paper, and not a "penny dreadful"; and though it may be too much to expect that Mr. Binns's drawings should resemble the objects he intends to portray, yet, at all events, they should be executed with some trifling degree of care. I fear that Mr. Binns has neglected to duly lay to heart the excellent advice tendered him by a "Fellow of the Royal Astronomical Society," on page 121, of Volume XXXIX. **H. Sadler.**

### THETA ORIONIS.

[23892.]—I BEG to thank "A Fellow of the Royal Astronomical Society," Mr. Gore, and others, for their answers to my question about Theta Orionis, &c. I have procured the number referred to by "J. C. L."—*i.e.*, No. 877, Jan. 13, 1882; but there is a curious difference between the angles given there by Mr. Sadler and those by Mr. Binns in the MECHANIC for the week before last.

Would "A Fellow of the Royal Astronomical Society" or Mr. S. tell me if there is any mistake in these two drawings? I see Mr. Binns says he made his on the meridian. Perhaps that makes some difference; but I thought the angles were shown correctly on the meridian but wrongly off, and I do not understand what Mr. B. says about "the cardinal points so nearly agreeing with each other." If the several drawings are rightly orientated, as seen on the meridian, should they not agree? But perhaps this is my stupidity. I see a small star near Mira Ceti—I suppose that alluded to by "Epsilon" (p. 462). It is very blue in my 7½in. reflector. Rev. T. Webb gives no measnres, but says "suspected of being connected with it." Would "A Fellow of the Royal Astronomical Society" give measures and say whether this is a fact, and would he or Mr. Sadler give latest measures of ζ Tauri, 80 Tauri, O. Σ., 98 Orionis, all in Webb, but I cannot see them separated, except O. Σ. (14) Orionis, angle 200°, distance ¾″ ? ? white, beautiful blue, or make out "pair *n.* a little *f.*" the latter star, spoken of by Webb, p. 361. Has this little pair closed up? I see bright star *s. p.* δ (Delta) Tauri, not in Webb, and not marked "D" in Proctor, and a very pretty little triple about 3½ minutes of time following, and 20′ south of 135 Tauri. It is a close pair of, say, 7 and 8 magnitudes, est. angle 70°, dist. 2¼″, with a very faint star about 12″, and *s. f.*; colours deep yellow, deep blue. There is a bright star nearly as large as the big one of the pair a long way *n. p.* Between this and 135, nearer this and in the field with it, with my power 148, a little *s.* of the line joining this and 135 Tauri, is a bright white pair about 30″ apart, or perhaps a little more. Will "F. R. A. S." look at these and say whether they are new? I am surprised such bright and beautiful objects are not in Webb; but I can hardly suppose them to be new discoveries. **J. W. Ruthven.**

### JUPITER.

[23893.]—ON Feb. 27, at about 10 p.m., turning my telescope on Jupiter, I was surprised at seeing Satellite IV. on the disc as a dark spot. I continued to watch it until about 11.30 when I had to retire; it was then near the central meridian, north of the equatorial belt, and almost as black as I have seen its shadow. I was not able to compare the two on this occasion, as I retired before shadow and ingress; but some of "ours" may have seen both, and therefore be able to say whether the Satellite was as dark as its shadow. Webb, in "Celestial Objects," speaks of those dark transits as uncommon occurrences, therefore I thought I would call attention to this one. My telescope is a 7in. mirror; power 250.

Bank Top, Darlington. **W. H. Harris.**

### DARK TRANSIT OF JUPITER'S 4th SATELLITE.

[23894.]—THE transit of the 4th satellite of Jupiter on February 27th was doubtless observed by others as well as by myself. The satellite presented the same black disc on the face of the planet that it did on March 12th last year. The shadow appeared on the planet two hours later, and, contrasted with the satellite, was but a shade darker and about twice as large.

The surfaces of the satellite must be constituted of different reflective matter, since the first and second are bright when they first enter the disc of the planet and then disappear. The third is grey, and the fourth black.

**William Coleman, F.R.A.S.**

Dover, March 2.

[23895.]—THIS unusual and beautiful phenomenon was seen by me on the evening of the 27th and morning of 28th February. It was peculiarly interesting, being dark the whole time of transit. The satellite and its shadow, when each were equidistant from the preceding and following limb of the planet, could not be distinguished from each other in colour; they were both of an inky blackness. When nearing the edge of the planet's disc there was a slight fading of the satellite's colour to dark grey. After egress it was very faint. I judged its light would be about equal to a 10th mag. star.

I used 10in. of 10¼ mirror, a splendid low-power Huyghenian eyepiece, and Barlow lens.

Wick, Christchurch. **E. Miller.**

### THE DOUBLE TELESCOPE.

[23896.]—THE letter of "W. T. N." (23850, page 539) opens up the very interesting suggestion of dividing any large object glass down the middle and using the resulting halves binocularly. I find that by hiding the two inner halves of any opera-glass o.g.—which gives the equivalent effect of "W. T. N.'s" suggestion—one sees the whole image through the two outer halves only, precisely as with two whole o.g.'s, but with much less light.

In the 3⅜in. o.g.'s of my double telescope their focal centres are brought to 2½in. apart (besides room for play of varying widths of eyes) by cutting off ⅜ths of an inch from their inner side, notwithstanding which their focal picture can be found only at the one particular central spot; so much so, that even on turning the instrument from a longer to a shorter range, or vice versâ, the width apart of the o.g.'s always requires readjusting to bring the picture into exact line of sight and prevent overlapping or the contrary effect.

I assume, therefore, that the focal image will still only be found in the exact centre of any object glass, however much it may be cut or mutilated, even to halving it; so that if an 8in. o.g. were divided down the centre, the focal image would be found only on its cut edge exactly half-way up.

To utilise those halves binocularly, the two 4in. wide and 8in. high sections must be mounted in an 11in. single tube 2½in. apart—eye width—with ½in. more for variation in eye widths = 11in. in all.

It is also natural to suppose that having only half the o.g. (although they give the entire picture which whole o.g.'s would give), the resulting picture would be illumined with only half the light of whole o.g.'s.

The questions then arise: Would half the light of one 8in. o.g. so treated equal or excel all the light of two 3⅜ o.g. reduced to 3in. each in width? And, having regard to the greater magnifying power of the former, how should the result of the divided 8in. be expected to compare with that of the two 3⅜in. (reduced to 3in. in width)? Our "F.R.A.S." could no doubt solve these questions if he will be kind enough to oblige. **Montmartre.**

### OBSERVATORY.

[23897.]—REFERRING to "M. A.'s" letter in your last (23868), whether the roof required fastening or not depends very much on its construction. If it is light, it is better to have some contrivance for this purpose; but if it is substantial, which on every ground I think the best, it is not required. I sent you a description of the construction of mine, which appeared, and was figured in No. 815, Nov. 5, 1880, page 210. (There is a printer's error in the size of the plate, which should be 6in. by 3in., 12ft. square.) The ring of the roof is here built up of three thicknesses of 1in. segments of planed flooring board 6in. wide, which is perfectly rigid, and has not warped in the least since it was put up. The rafters for shutters and behind are 3½ by 2in., the others 3½ by 1¼in., covered with canvas. This makes a substantial roof, and has weight enough not to be moved by the wind. It revolves on eight rollers, 4in. diam., 2½in. wide, in iron frames fixed to the plate, and there are also eight vertical rollers 4in. diam. 1½in. wide, running on pins in strong iron brackets 6in. wide, fixed also to plate, with two strong bolt screws which have slots in them to adjust the rollers as near the ring as required. They were set when first put up ¼in. from the ring, and have never been moved since. The ring simply rests on the rollers, and is kept in its place by the vertical ones, and can never jam in any way; it generally only touches two or three of the vertical rollers. Care was taken in fastening the segments of the ring together, that there should be no nails where it runs on the rollers. These were placed towards the edges.

The roof is easily moved by the hand, or by two single 3in. blocks, a hook being placed at each angle of the plate to move the block where required. This is much better than any system of flange wheels, or "live ring," or balls or grooves, and is the plan adopted by Mr. Grubb in the large dome for the great Vienna refractor. I have my doors (two folding doors 2ft. each) to open outwards, and windows also, which are glazed with 21oz. glass, so that they can never blow in, and I always keep the roof with the shutters towards the wind, and tied down to the plate in rough weather, though in this position there is no tendency to blow open.

Fordingbridge. **T. Westlake.**

### A PLEA FOR GOOD MANNERS.

[23898.]—IN lecturing upon astronomy I often have had occasion to refer to much valuable and interesting information in the ENGLISH MECHANIC. I feel that your paper brings such information before a very large number of readers who might not otherwise be interested in the subject, and I think that it is most desirable that all English Mechanics should be as highly educated as possible, and I believe that it is your wish to help them to be so. Now surely one great advantage of education ought to be its humanising effect, as suggested by the well-known phrase "Literæ Humaniores." It may no doubt be easier to be a gentleman *both* by birth and education, than by education *alone*, without that special advantage of birth which, if I remember rightly, a certain distinguished Lord Chancellor once described as the accident of an accident in the case of many of his *confrères* in the House of Lords. But all education, all study of science, such as you encourage in your readers, ought to tend to make them gentlemen by education. This being so, may I, as one of your readers who has often felt much indebted to your paper, earnestly appeal to you in future not to allow in scientific articles, even by way of jocosity, such expressions to appear as that in your last number in reference to "Christie Minstrels," as well as other somewhat similar personalities to which I might refer?

Quite apart from the question whether the members of the Royal Astronomical Society are not capable of judging whether they will choose to vote by proxy or otherwise, or whom they will have on their council, I must say that I think the writer of certain letters in your paper signed "A Fellow of the Royal Astronomical Society" does from time to time use expressions which make it, to say the least, unpleasant to read the said articles. They also make me feel it difficult to refer my audiences to your paper for information when I should wish to do so, because I feel that such a style of writing does not tend to produce that humanising effect upon readers which I have already said all study of science should produce. I also feel it rather hard that such articles should not either be signed with the full name of the writer, or simply by some initials. Why should I, or any other F.R.A.S., be liable to be supposed to be the possible author of the phrases or statements so signed? It is, I hope, and trust it will long be, an honour to hold the title F.R.A.S.; and it will be so if those who hold it are careful as to whom they may recommend for election; but it seems to me that it may some day be necessary to make some regulation that the title shall not be used as a signature to anonymous statements, if such use of it is injudiciously made. I have, I think, read that once upon a time, when a special honour had been conferred upon one of the Manners family, who thereby was so elated that he forgot his good behaviour, it was remarked that the old family motto, "Manners maketh man," might be changed to "Honores mutant mores." I would trust that the holding of the title "F.R.A.S." may never have this latter effect. Let all that is said about science be gently said, with good taste and kindly feeling. A noble science surely deserves that it should never be spoken of in ignoble language.

**Edmund Ledger.**

Gresham College, Feb. 28th.

### THE MUSICAL SCALE.

[23899.]—THE point at issue between "A. S. L." and Mr. N. E. Child is plainly the meaning attached to the word "scale." The latter gentleman evidently uses the word to mean the "mathematical relationship of the tones to one another" (about which "A S. L." speaks on page 453), while "A. S. L." takes these proportions, and, starting from different keynotes, supposes that with each keynote he creates a new scale. There has always been some confusion upon this point—no doubt arising from our having been taught about the scale of G, the scale of C, &c., instead of the scale *on* G or *on* C, &c. Johnson says scale means "ladder, means of ascent, regular gradation, *series* of harmonic or musical proportions"; and it is clear the measure is here denoted, rather than the series of notes after they are measured off: otherwise he would have said series of harmonic or musical *notes*. No doubt other dictionaries would bear out this view; but I cannot refer just now. The marks on a carpenter's rule represent the scale by which he works, and if he transfers these to another piece of wood, he does not construct a new scale, only copies the old one. If we accept "A. S. L.'s" view of the meaning of the word "scale," then are there an infinite number of scales, there being an infinite number of starting points, only limited by our capabilities of division and our ability to hear high or low sounds. The inverted commas in "A. S. L.'s" letter, page 453, go for what they are worth, because we all know how carelessly worded some of our standard textbooks are.

The natural musical scales appear to arise out of the demand of musical ears for simplicity of ratio between the notes chosen from which to construct our music. The simplest ratio 1 to 2 gives the octaves, 2 to 3 the fifth, 3 to 4 the fourth, 4 to 5 the major third, 5 to 6 the minor third; while 3 to 5 gives the major sixth, and 5 to 8 the minor sixth. These are all consonant with the keynote taken to start from, which, of course, is represented by unity, or 1 to 1. They are also consonant, or in simplicity of ratio, with each other, provided the interval between them is not less than makes a concord, and that the third and sixth be both major or minor. Thus, the interval of the minor third, or 5 to 6, exists in purity between the keynote and minor third, the major third and fifth, the fourth and minor sixth, and the major sixth and octave. The interval of the major third, or 4 to 5, exists in purity between the keynote and major third, the minor third and fifth, the fourth and major sixth, and the minor sixth and octave. The interval of the fourth, or 3 to 4, exists in purity between the keynote and fourth, the minor third and minor sixth, the major third and major sixth, and between the fifth and the octave. The interval of the fifth, or 2 to 3, exists between the keynote and fifth, and between the fourth and octave, all which can be easily proved by fractions, thus:—The ratio of the major third may be set down as $\frac{4}{5}$, and the minor third, or $\frac{5}{6}$ths of this, is $\frac{4}{5} \times \frac{5}{6}$, which equals $\frac{2}{3}$ or the measure of the fifth, showing there is an exact minor third between the major third and the fifth, and so on through the series.

Now, there are two large gaps at each end of the scale not yet filled. But we shall find no notes there that will be consonant with the keynote, as all our other notes have been; for there can be no concord less than a minor third until you reach the unison, or greater than a major sixth until you reach the octave. The modern musical ear, however, demands something in these spaces before admitting any scale complete. Take the major second of the natural scale first. We shall find, if we adopt that note which is an exact fourth below the fifth of the key, that the ratio with the keynote will be 8 to 9; but if we take that note which is an exact third below the fourth, or an exact fifth below the major sixth, the ratio with the keynote will be 9 to 10. And if we go to the corresponding place at the other end of the scale, and seek for the flat seventh, we shall find the note which makes a perfect fourth with the fourth of the scale to be in the ratio of 9 to 16 with the keynote; while the note which makes a minor third with the fifth, or a fifth with the minor third, will be in the ratio of 5 to 9 with the keynote. This shows that for perfect harmony we require the major second and minor seventh to be double, and there is no doubt that true musicians produce these on voices and strings and any other just-intonation instruments. Herein probably lies the explanation of the difference between the major seconds existing between the fourth and fifth, and between the fifth and major sixth of the scale. These major seconds are not alike, the former having the ratio of 8 to 9, while the latter has the ratio of 9 to 10.

Now, if we seek the major seventh, which the modern musical ear demands as a leading note to the octave of the keynote, we shall find that a major third above the fifth, or a fifth above the major third, will be in the ratio of 8 to 15 with the keynote, and if we go to the corresponding place at the other end of the scale, we shall get the minor second in the ratio of 15 to 16 with the keynote, making a major third with the fourth and a perfect fifth with the flat sixth. These intervals are all pure, and if it be desired to construct scales on C, setting them out in the following table will help us:—

| | Ratio. | | |
|---|---|---|---|
| C, keynote | 1 | or | 1· |
| D flat, minor second | 15/16 | " | ·9375 |
| D grave, major second | 9/10 | " | ·9 |
| D acute, major second | 8/9 | " | ·888 |
| E flat, minor third | 5/6 | " | ·833 |
| E, major third | 4/5 | " | ·8 |
| F, fourth | 3/4 | " | ·75 |
| G, fifth | 2/3 | " | ·666 |
| A flat, minor sixth | 5/8 | " | ·625 |
| A, major sixth | 3/5 | " | ·6 |
| B flat grave, minor seventh | 9/16 | " | ·5625 |
| B flat acute, minor seventh | 5/9 | " | ·555 |
| B, major seventh | 8/15 | " | ·533 |
| C, octave | 1/2 | " | ·5 |

Now, the sounding of these notes one after the other would not constitute a musical scale, as understood by the musical ear, but would appear to be a musical scale with several foreign notes interpolated. The natural major scale on C ascending would be C D acute E F G A B C, and descending G B A G F E D grave C, as the ear prefers the large tone to the small tone when choice is offered. For proportions reference can be made to the table. Of minor scales several are believed in, that on C (in modern use) being C D acute E flat F G A B C ascending, and descending C B flat grave A flat G F E flat D grave C; there is also the scale C D acute E flat F G A flat B C and C D flat E flat F G A flat B flat acute C; the old Scotch scale of C D acute E G A C, and the scales of some barbarous tribes with less notes than this; but there are no intervals found in any of them that do not appear in our own modern major scale, and consequently there is but one natural scale, and that is it. The minor mode is simply a setting up of the sixth as a governing note instead of the keynote, and paying homage by ascending as you would to a keynote. It may be argued that some people (untutored savages, for instance) do not sing their notes in these proportions to each other, and consequently there are other proportions and other scales. Do we not know, from sad experience, that our friends depart from these simple proportions and vex us?—and we say they sing out of tune, not that they use other scales; and if we sought out the natural musicians among these savages, I believe we should find these sweet singers using the notes of our own major scale, omitting those they have not learnt to use.

Now, the beauty of these natural intervals is admitted on all hands; musicians invariably receiving praise when they perform them, and tempered intervals are an abomination to the true musician? Can we not get these pure intervals in some way from our keyed instruments, which are now so universally used, and so cease from spoiling good ears by bad models. **S. E. Hunt.**

## MR. BOTTONE AND HIS PRIVATE CORRESPONDENTS.

[23900.]—I HAVE received over fifty letters last week asking for advice on electrical matters. Out of these fifty three contained stamps for reply; the rest were distinguished by requiring information of the most intricate kind, without any idea of the loss of time this entailed. Among these latter, a gentleman hailing from Lambeth sent me as a kind of riddle a piece of silk, which he says is largely used by a German electric company, and wished to know what the company uses it for. Evidently it is used for insulating purposes. But how much better it would have been to have asked these questions in the columns of the ENGLISH MECHANIC, when all would have profited by the replies.

Except in very urgent cases, I must decline answering querists privately—especially when they do not care to pay for postage. **S. Bottone.**

## SCREW-PLATES—LECLANCHE CELLS—WOODEN CHUCKS—VICES—QUININE AND OIL — REFINING SILVER — POLISHING WOOD—ZINC ROLLING—SCREW-CUTTING—THE MARCH OF INTELLECT—OUR UNCONQUERABLE CORRESPONDENT.

[33901.]—As I have been unable for several weeks to send my usual quantum of replies, I should like to notice a few queries which have appeared during the past month, some of which have been more or less answered. In the first place, I would say, Don't attempt to make a screw-plate (55821) for anything larger than ¼in.; they are most unsatisfactory to use, and you will waste a lot of time and temper. I sometimes use one made from an old file for screwing brass gas threads, but they are no use for iron. If you cannot afford to buy dies, you might meet with an old secondhand die stock. You could then file up and cut some dies, which would give you years of work.

It is not always sulphate of zinc which forms crystals in Leclanché batteries (55844). In fact, I don't altogether see how sulphate of zinc is to get there at all (*vide* page 526). The solution has a habit of creeping up and over the sides of the glass vessels. It will then evaporate, and leave a film of ammonium chloride both inside and out, and it will even form stalactites, which will hang like miniature icicles from the bracket on which the batteries stand. Crystals of sal-ammoniac will not dissolve in water *at once*, and a novice might infer that they were insoluble. Remedy, slightly warm the empty glasses, or cells, and cover them for about an inch from the top, both inside and out, with a varnish composed of sealing-wax dissolved in methylated spirit; gather up the crystals, put them back and add more water. Always see that the cells are half-full of water, and if the addition of water won't make them ring the bell, add some sal-ammoniac, and see that the zincs are not worn out. My batteries have been working eighteen months; they have had in the interval nothing but water, and I have had no occasion to examine the zincs.

The best way to screw wooden chucks (55848) for the lathe is to use a tap; but it is rather difficult to make a tap enter the wood to a sufficient distance to enable it to hold; that is, it gives way and strips the thread. To obviate this disadvantage use a piece of iron or brass plate which is already tapped; this is screwed to the base of the chuck, and serves to hold the tap while it cuts a correct thread in the wood. I put brass plates on all my wooden chucks, in which case I don't cut the thread in plate until it is screwed to the chuck. I think I should look at a piece of wood and a lathe a long time before I should attempt to cut such a screw with back gear and slide-rest. The chuck is, of course, turned up afterwards.

In screwing pipes and rods (55906) with dies, it is a great advantage to have a special set of jaws for the vice. Malleable cast iron will do very well. These jaws should be just filed to fit the vice, and be drilled through at the joint to fit the pipes and rods mostly in use. They will give a better grip than the bare jaws of the vice, and will prevent pieces of pipe from being done to death.

Quinine (55719) can be dissolved in almost any oil without the use of chloroform, and without using almond oil as a special solvent. Procure the ordinary sulphate, mix with the proper quantity of water, and add sufficient dilute sulphuric acid to dissolve. Now add ammonia till all the quinine is thrown down or precipitated; wash this precipitate with water, and allow it to get moderately dry. The application of a little heat will now cause it to dissolve in oil. Cod-liver oil is most generally used, and it is not necessary to heat the whole quantity of oil, as a small portion can be used, and when cool, mixed with the remainder.

The best method of making nitrate of silver from alloyed metal is that given by "Bobadil"; but after dissolving the alloy in nitric acid, the solution should be neutralised; that is, sufficient soda or other alkali should be added to correct the unavoidable excess of acid; the solution should be stirred with a glass rod (or piece of wood) while the alkaline solution is being added, and the instant the least permanent precipitate or cloudiness appears, desist from any further addition. The solution can now be filtered (or cleared by subsidence), and *clean* strips of copper inserted. The object of neutralising the solution is, *inter alia*, to save the copper, as the free acid will at once commence to attack the copper, and this, for several reasons, is undesirable.

The correspondent (55984) who says he is a French polisher, and wants to know how to polish work in the lathe, had better follow the usual routine while his work rotates in the lathe.

For all practical purposes cast zinc is, for batteries, quite as good as the milled variety (55987), and it can be made absolutely as good by a judicious application of the hammer. If there is one thing in all the world which can't be done by looking at it, that one thing is zinc rolling: don't attempt it, it will end (if not in vanity), at least, in a good deal of vexation of spirit (and pocket). I pay 1½d. per lb. for scrap zinc, and at that price I can afford (as an old employer of mine used to say) to have something to "come and go at"; but, then, I don't make my batteries to sell, and if I did I should sell such as I would use; rolled zinc ⅜in. thick, which is about as thick as can be bought, is only a plaything in batteries. It may, or may not, be of service to "L. W." (55993) if I suggest that his work could possibly be bolted to the saddle, using a long cutter-bar. I look upon the letter of "O. J. L." (23874) as a sign of the rapid march which intellect is making. He is to be congratulated on the possession of an unlimited quantum of moral courage—congratulations which I cannot offer to the writer of another letter (23873) which terminates on the same page. Vituperation certainly shows that a writer (who uses it) lacks courage or ability to meet his opponent in a fair way. It is just possible that "Invicta" may *not* be an old correspondent under a new name; but for some time past I have thought that there are some people who would like to know where he lives. It does not matter if he does call me insolent and ignorant, as I shall only give him permission to call me—well—something else.

**Os.**

## THE STATE OF MAN.

[23902.]—"O. J. L." (letter 23874) constantly refers to "the Creation" and "Adam and Eve" as Mosaic. This is to be regretted, as the history of these two events was as unknown to Moses as it was to Solomon or any other of the Israelites until after the Captivity. The Jews brought these back with them—Adam and Eve as a legend, or probably old ballad; and the Creation as a modern writing of singular power and beauty, in grammar and imagery—a thousand years in advance of anything written by Moses. If the Apostle Paul had not referred to Adam, the story would probably have ceased for ever. **Priam.**

## GAS-ENGINES.

[23903.]—STRANGE as it may seem to your correspondent who, on p. 558, appears to have lost himself, I am still of the opinion that all that it is possible to say about the gas-engine has been said in these pages. He apparently forgets that the 40th volume is just concluded, which means twenty years, and if he will search through the volumes he will find not only articles, but many valuable papers on the subject, besides innumerable letters and replies. It is, of course, possible to say many things about the gas-engine which are not true; but even on that head I maintain that my statement is perfectly correct, for if the back volumes of the "E. M." contain much that is sensible and to the point, they also contain items here and there which are simply nonsense, *e.g.*, in Vol. XXXIII., and, if your correspondent will forgive me for saying so, even in Vol. XL. I would suggest to "Invicta" that he should give us a little less "gas" and a little more "engine," and though I do not doubt that he is a master of "impertinence" and "courtesy," I would point out to him that his reply to my simple question about the cost of gasoline gas was literally and absolutely impertinent, for, instead of answering the question, he avoided it altogether, and, as usual, told your readers what he could do "an he would." We are all willing to learn; but at present "Invicta" has taught us nothing. Will he commence by giving us straightaway a design for a gas-engine as he thinks it ought to be? **A. Sieger.**

### GAS-ENGINES.

[23904.]—I am very much disappointed with "Invicta's" reply to my challenge. After the way he commenced to write on this subject, I fully expected he would have given some information about the extraordinary gas-engines he has had so little experience with, especially as he offered to give us the practical information that myself and other writers were so ignorant of, and still persists in his statement *re* gasoline for the Otto engine, and writes that the person who made the oil-gas apparatus informed him that on a test being made by Messrs. Crossley with the gas, their engine needed no alteration. The authority for my statement was the representative of Messrs. Müller (the makers in question), who informed me that Messrs. Crossley had written to their firm declining to have anything more to do with their gas generators, on account of the trouble they had in getting the valves and firing arrangements of the correct size and shape. I am sorry that "Invicta" has forgotten the address where he saw the gas-engine using a mixture of 20 vols. air to one of gas; but he refers me to Mr. Clerk's paper on his gas-engine for that highly successful engine giving off a duty of 17·83 per cent. I have since read that paper, and to my surprise find that this is the source that "Invicta" has obtained the knowledge from regarding the consumption of gas and the mixture used in the Otto, Lenoir, Hugon, and Brayton, and Sir W. Siemens's regenerative engine. His statements are portions of the paper he refers to, being twisted about to suit the different queries he replied to. As this paper makes no mention of the Ord or Bisschopp engines, it can only be assumed, that is why "Invicta" did not know the ratios of gas and air used in them. Mr. Clerk, in his paper read before the Institution of Civil Engineers (session 1881-82, Vol. XLIX. part 3) stated that his engine consumed 22 cubic feet of Glasgow gas per indicated horse-power per hour; and 17·83 was only an approximate estimate of the efficiency of his engine from the indicated horse-power, assuming that Glasgow gas had a heat capacity of 505,000 heat units per cubic foot. The consumption of Glasgow gas per brake horse-power was 29 cubic feet per hour, and Dr. Adams, in the correspondence that ensued, afterwards pointed out that by a recent analysis of this gas by Dr. Mills, the heat capacity was 735·588 heat units per cubic foot. This works out nearer 11 per cent. than 17·83.

I have yet to learn that Dr. Siemens, Professors Rucker and Kennedy, Drs. Hopkinson and Adams, Messrs. Imray, Bousfield, Davey, and the other well-known gentlemen were converted to Mr. Clerk's theory, and that the believers in slow combustion were so refuted as "Invicta" seems to imagine, especially after the same size of Clerk engine went to the Crystal Palace Exhibition, 1882, where, in competition with the Otto, it consumed 63 cubic feet of gas per brake horse-power. As "Invicta" is writing to the inventor, perhaps he will ask about this also, and oblige the readers with his reply.

I may mention that I am in no way connected with either gas-engine makers or sellers; but, perhaps unfortunately for "Invicta," I am in possession of the knowledge, and have a slight connection with the low-pressure steam motor mentioned by him that is made of cast iron—perhaps the one that he has been experimenting upon to determine the proper sizes and forms for the different powers. I have great pleasure in informing him that one of these motors is on exhibition in London, and that it works at less than ¼lb. per square inch, and very often it is working below atmospheric pressure with a vacuum inside the boiler, and the consumption of coke is less than 9lb. per brake h.p.

This cast-iron motor or safety engine is made at Leeds, and known as the Domestic Motor—Davey's patent, No. 3833, 1884. It was exhibited at the Dairy Show driving a cream separator, and has been described in *Engineering* and the *Electrician*. As "Invicta" seems burning with a desire to give a description of his new cast-iron steam motor, and to air his knowledge of heat and its uses, I shall be pleased to see this description, so that I can judge if he has been copying other inventors' ideas from the patent specifications.

If his experiments are not yet complete enough to give the description asked for, and he will publish his address, I will communicate with him, as I can show him one of these motors that does not require a safety valve, it being open to the air like an ordinary teakettle. As "Invicta" is able to set Siemens's people in the right way of making a success of their regenerative engine, in the next issue we may expect to hear that he is the inventor of the condensing engine, and that James Watt knew nothing whatever about steam, or studied heat and how to utilise it, as he says he has done. Finally, I would recommend "Invicta" to ascertain that the statements made in advertising testimonials and papers published by interested persons are correct, before again attempting to pass them off on the readers of the "E.M." as his own experience—especially the statement about the gas-making machine that will make gas of good illuminating quality at ninepence per thousand feet. **R. A.**

[23905.]—In my opinion, although "Invicta" has taken up over a column (letter 23873) trying to prove that "black is white," he has not in any way disproved the statements of "R. A.," and only quotes the inventor's statement with regard to the consumption of gas in the Clerk engine. I have seen the register of gas used for a Clerk 2 h.p., and it has shown a consumption of quite 50ft. per hour, and the engine was not doing anything like its full work. I was looking about after a gas-engine some time ago, and the "Otto" people were the only ones from whom I could get any exact statement as to gas used.

I went to every place in London where engines were for sale, and from almost everyone of them I got the same stereotyped reply on the gas question, which was, "It costs *about the same* as Otto's." Well, at last I bought one, and it had not been at work long before I found it used 60ft. of gas per hour.

Now, the Tangye 1 h.p. engine at its utmost requires between 60ft. and 70ft. per hour. What is the cause of this? And how can the engine be made to use less? Will you kindly explain?

I should like further particulars about the engine that uses from 15ft. to 18ft. per hour. You say it is to be seen in Leeds. I should like to see it myself; but as you give no name, and Leeds is a large town, I cannot spare time to make a house-to-house inquiry. I cannot help thinking that if the engine was so successful as you state, we should have heard more about it, and there would have been no occasion to go to Leeds to see it. On the whole, I think that your letter very carefully evades the original question, and unless you give the information asked for by "R. A.," I, for one, shall regret the space wasted by printing your letter and the time lost in reading it, and, no doubt, with all our readers judgment will go by default. **Volt.**

### SHORTNESS OF STEAM IN LOCOMOTIVES.

[23906.]—I gather from the criticisms of several of your correspondents on the failure of some of the new Midland engines, that they attribute it to shortness of steam. Below you will find a description of the method I adopted in a somewhat similar case which had the advantage of being both effective and inexpensive.

Having fitted up several locomotives in Mexico some time ago, two of which were of English construction, in making trial of the two English engines I found, in going up an incline of 2 per cent., the steam fell away rapidly. The above engines were constructed to burn wood. To remedy the above defect, I shortened the exhaust pipe down to the third bottom row of tubes, and sharpened the exhaust by making the hole in the mouth of the exhaust pipe a little less, and then added a petticoat or crinoline. I found I had abundance of steam. **Exhaust.**

### NEW BRAKES.

[23907.]—Mr. G. Mitchell (p. 168, 55931) says the new Midland brake is the same as the one on the Lancashire and Yorkshire: he has made some mistake. The L. and Y. brake is Smith's automatic vacuum, and has a sleeve round the piston-rod and a separate reservoir. The Midland has a packed piston-rod, and no additional reservoir. The principle may possibly be somewhat the same, but the apparatus is very different, and goes by another name.

It is quite true the two-minute Midland Clayton leak-off brake is to die; indeed, the leak-off dangerous hole is being done away with at a great rate—that is, fifty carriages a week are having it altered. This new "ball-valve" brake only began on Monday, 16th February, but it soon gives a lot of bother: it sometimes won't come off; it sticks; and if you want to change an engine or shunt a carriage, the vacuum brake goes "on," and there you are fixed till you go down the train and pull cords under each coach, just as bad as it was when we had the old Sanders brake, seven years ago.

There are a lot of changes going on just now. The North-Eastern are going to do away with Smith's vacuum and work only Westinghouse on the Scotch trains.

The Great Northern are going to take off all Smith's vacuum, and intend to adopt the automatic vacuum, in place of the non-automatic. This is one of the results of the Penistone accident.

Then there is the South-Eastern going to go in for the "ball valve," and do away with Smith's vacuum; and yet, what they are doing away with is just what the North-Western is putting on. The London and North-Western will soon see the end of the chain brake now; by July next, they say at Wolverton, there won't be a chain brake left on the line.

The Tilbury and Southend fitted a lot of new stock not long ago with the chain brake: it has all got to come off and be thrown away, and they are putting on Westinghouse as fast as they can.

The Midland is taking the steam brake off the passenger engines and putting on the vacuum; so you see, Sir, there is a fine lot of changing going on just now.

What an amount of money has been spent in the kingdom upon fitting and changing brakes—and yet the subject seems as far off a final settlement as ever. **Driver.**

P.S.—Will any correspondent oblige by giving details of the new Midland brakes

### NEW MIDLAND ENGINES.

[23908.]—In reply to Mr. J. Kean, I may state that the run referred to with the new Midland 19in. cyl. engine was made in September last, when those engines began to run in the Nottingham fast expresses. The speeds of 75 miles an hour and upwards were attained in every case on falling gradients varying from 1 in 200 to 1 in 100, viz., below Ampthill and Sharnbrook and approaching Saxby and Nottingham. I have not any full notes accessible here, but will endeavour to send details next week. I may say, however, that the maximum speed reached was about 76 miles an hour, the train consisting of nine coaches, and the weather being fine with dry rail.

Liverpool, March 2. **C. Rous-Marten.**

### MANGANESE STEEL.

[23909.]—In reference to a paragraph which appears on page 571, Vol. XL., I have been using manganese steel since Christmas with the very best results.

The difficulty with Bessemer steel is that it will not stand case-hardening to any extent; but, instead of receiving a hardened skin, seems to be penetrated clean through and rendered as brittle as gingerbread.

On receiving some bars from Messrs. Pfeil and Co. I cut a 3in. length from a ¾in. rod and turned it all over; in the middle of its length I cut a nick 1/16in. deep with a V-pointed screw tool. This piece was afterwards subjected to a case-hardening process for three hours and allowed to cool in the fire; subsequently, it was heated and quenched in cold water, which left the outside as hard as hardened cast steel.

It was afterwards suspended on a swage block, and required three smart blows with a 14lb. hammer to bend it to a curve, the versed sine of which was ¼in., and then showed no sign of fracture at the nick, which had been provided for this purpose. Seeing that the amateurs are still—will they ever finish?—discussing the material and form of their lathe mandrels, I beg to state that, in my opinion, there is no material in the market so suitable as this for the purpose. **W. J.**

### SLIDE-VALVE DIAGRAMS.

(*Continued from p.* 541, *Vol. XL.*)

[23910.]—I now come to the Zeuner diagram, which is one of the simplest.

I will take as an example the same value as that which gave the diagram shown in Fig. 15 (p. 541). As in the former figures, draw A G—to any scale—to represent direction and length of stroke of piston. Bisect at $p$, and draw the perpendicular $J p D$.

Set off the angle $D p y$ ($= \theta =$ the "angular advance" of eccentric). Thus: Make $l p$ equal to the lap, and $l d$ equal to the lead, at the top end (that furthest from the crank) of cylinder. Draw the perpendicular $d y$. With the throw of the eccentric as radius and $p$ as centre, draw an arc cutting $d y$ in $y$.

Join $y p$. $D p y$ will then equal $\theta$.

On $p y$, as diameter, describe the circle $d y m p$,

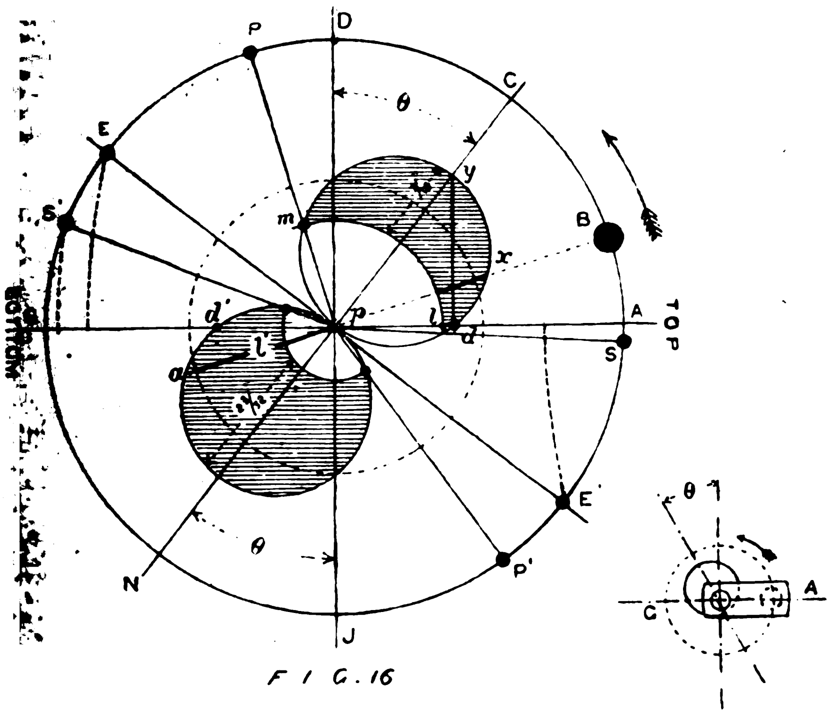


FIG. 16

and call it the top valve circle. The length *p x* cut off any radius *p* B by this circle is the distance the top steam edge of valve has moved from mid-position when crank-pin is at B.

As no steam can be admitted until the valve has moved a distance from its mid-position equal to its lap (See Figs. 1, 2, and 6, page 143, Vol. XXXIX.), we must deduct the lap from *p x*, and this is most readily done by describing the arc *l m* about *p*, with a radius equal to the lap. The part of any radius *p* B included in the shaded space between the arcs, as at *x*, is then equal to the amount of opening of the *top* steam port when crank-pin is at B.

We thus see that steam is admitted when crank is at S; that valve is opened ¼in. at B, $\frac{7}{16}$in. at C, and cuts off at P.

Produce *y p* and on it describe the circle *p d' a* with a diameter equal to *p y*. The length *p a* cut off the radius B*p* produced by this circle, is the distance the bottom exhaust edge of valve has moved when the crank-pin is at B.

As the ports are supposed to be only ¾in. wide, it is obvious that, though the exhaust edge may move through a greater distance, it cannot open the *port* more than ¾in. Hence, if the dotted circle is drawn with a radius of ¾in. we see that the exhaust is as free as possible when crank pin reaches a point between A and B; that it remains full open until the crank is at a point between D and P; and that it closes at E, having opened at E'.

Where, as in this case, there is no exhaust lap, E E' is a straight line at right angles to *y p*.

In considering the steam admission to the lower end of cylinder, the lower circle is used; the "lap circle," in this case only $\frac{9}{32}$in. radius, being described about the centre *p* cuts *p g* in *l'*, giving the lead *l' d'* = $\frac{1}{32}$in. for the bottom end of the cylinder.

Here, as before, the space between the lower valve circle and the lap-circle gives the opening of steam port at the bottom end, and the produced radius is cut off by the top valve circle to a length equal to the exhaust opening at the *top* end of cylinder.

Thus, when crank is at S', steam is admitted to bottom end of cylinder, the exhaust at top being open $\frac{9}{32}$ (found by producing S' *p*) until cut by the top valve circle; at H the steam to bottom is $\frac{11}{32}$ open, and the top exhaust is ¾in.

At P' the steam is cut off at bottom and exhaust at top is $\frac{9}{32}$ open; at E' exhaust opens at bottom and closes at top; at S steam opens to top, the bottom exhaust being open $\frac{9}{16}$; at B the top steam is open ¼in., the bottom exhaust being ¾in.; at P steam to the top end is cut off, the exhaust at bottom being $\frac{9}{16}$ open; at E the top exhaust opens and the lower one closes.

The positions of piston may be found either by striking arcs, as in previous examples, using the connecting rod as radius and placing the one leg on G A produced, or as in Fig. XVII. If the first method is used, the centres of the arcs must be on the same side of D J as the top valve circle *d x y m*. Note, also, that in drawing this diagram the angle θ is drawn on the side of D J next the cylinder, not away from it as it really is (see small sketch of crank and eccentric).

**Glatton.**

## INTERCHANGEABLE MANDRELS.

[23911.]—Could not an accurate fitting of chucks upon the mandrel-nose be insured by the following means?—viz., make the mandrel and chucks with a cylinder fit at both ends, and with the screwed portion between them. Of course, the cylindrical part at the end of mandrel-nose would have to be smaller in diameter than that next to the mandrel face, viz., a shade smaller than the diameter of the nose measured at the bottom of the thread. With chucks which require to be reversed, or in cases where the contracted diameter of the front hole in chuck would be considered objectionable, the required fit upon the front end of nose could be obtained by inserting a bush (in the form of a ring turned perfectly true inside or out) in the central hole of chuck, such bush being of the same external diameter as the cylinder part at the back of the screw on mandrel, and of course fitting the front cylinder part in its internal diameter. I should think with these two cylinder fits made as long as possible and truly parallel, combined with a face fitting of large diameter and a good fit in the screwed part, that very great accuracy would be obtained, and also durability, for, with careful usage, it would be a long time before the cylindrical parts (especially if made of ample length and with no taper whatever in them) would wear sufficiently to throw the chuck out of truth. The ring bush would, however, probably be an element of uncertainty.

I have only read a *few* of the recent letters upon this subject, so possibly the above simple expedient has been advocated by others in these pages, or there may be some fatal objection to its use which I have overlooked.

**Wm. Granger.**

---

[23012.]—"Z. Y. X." gives us some further data about "bort." The "black diamond," when a homogeneous, well-shaped crystal, is of course a *gem*, just as Mr. Hope's blue diamond is. Such very rare stones are not now in question. There are three distinct sources of bort.. The first is the "carbonado" or "carbonate." The second is the misshapen or badly-coloured diamond crystals, which are only useful for breaking up into diamond dust. The third is the dust which comes off in the primary outlining of the rough gem diamonds. This primary outlining is, to some extent, effected by fixing two rough diamonds in handles by means of cement, and then skilfully rubbing them against each other so as to make them abrade each other and roughly outline the facets which are to be formed by subsequent grinding upon the revolving iron skyf charged with diamond dust. Bort so obtained is of a peculiar grey colour; but under the microscope it is seen to be composed, as I have already said, of minute, transparent sparks like broken glass or diamond crystals of microscopic dimensions, and it is entirely destitute of colour. The dust thus abraded is carefully caught in a little box, and is afterwards graded by sifting or elutriation. The misshapen or badly-coloured crystals, which are unfit for use as gems, and will not come in for other purposes, are broken up in a hard steel mortar to the requisite fineness, the useful sparks are picked out by means of a lens, the remainder is purified from particles of steel by means of a magnet, or by nitric acid; it is then graded by sifting or elutriation. The carbonado or carbonate is broken up in the same way. I am not aware that, for such purposes as trueing-up hard steel, there is any choice as to the source whence our diamond dust is derived.

I happen to have collected a good many diamond tools myself, and to have given some attention to this matter. I find that all my glass-cutting diamonds are of the boat shape, with the double-curved natural edge. These stones only cut well when used at a particular angle, and when moving on a line with the run of their keel. Used upon copper or steel plates they only grub out their lines; they do not excavate them as the etching needle excavates its line in the copper or steel plate. Writing diamonds are not natural crystals, but *sparks*, and they produce a scratch on the surface; but do not cut glass so that it will divide. An edge, or a solid angle derived from the outer surface of a crystal, is said to cut best and to last longest. These sparks cut best at a particular angle and in a particular direction, which will soon be felt and learnt for each tool if its owner has his fingers properly soldered on. Diamond drills are made of steel slightly widened out at the end, sawn down for the insertion of the diamond spark so as to project at each end crosswise, and then gently hammered together so as to hold the spark safely. Such a tool will drill glass, or china, or quartz quite easily if lubricated with paraffin or turpentine. Cutting tools intended to act as gravers are of very fine coke-like or flint-like texture, brownish-black in colour, and set in hard brass. The larger ones are set in soft steel.

As to the emery powder, I do not think I need add anything to what I said at page 542. If our contributors would only examine these things under the microscope they would see at once why the grinding action of a given abradant differs from the polishing action of a true polishing powder.

Both "Z. Y. X." and Mr. Wenham have an objection to the action of grinding laps, and recommend that we should "pare away" our hardened steel by means of a cutting diamond tool. Mr. Wenham even writes: "Some of our best lathe-makers now prefer to true up their hardened steel mandrels by a diamond-turning tool." I should be glad if Mr. Wenham would name one tool-maker who thus shapes hard steel. If anyone can exhibit a single object of such size as a lathe-mandrel in hard steel shaped in this way, I shall be glad to see it and report upon it. I believe that it is an entire mistake, due to paper-theorising, to say that any one of our tool-makers does this. Whitworths *grind up* their beautiful steelwork. Smith and Coventry, of Manchester, shape their beautiful hard steel cutters by fine emery grinding-wheels on the principles which I have described. None of our ornamental lathe-makers make their hardened steel traversing mandrels otherwise than by grinding. The real fact is that pieces of diamond of the proper shape for paring away hard steel are extremely difficult to set in such a way that they are safely held so as to do any quantity of work, and their work would never be so smooth as that of the accurately-made metal glazing wheels.

Mr. Wenham makes another suggestion, which upon paper is pretty, but in practice is misleading, and can never have been tried by him. The use of a revolving wheel to press the diamond sparks into the edge of the slicer is not necessary, because the razor back or smooth agate, as used by the lapidary, answers perfectly. The inertia of the razor blade is quite enough to imbed the diamond particles in the metal, and it can be *felt* in its action when held in the hand. The revolving wheel could not be felt in this way, and when cut into would be useless for the future. Then, for other wheels than the slicer, their face-contours would need for every variation an exact counterpart wheel. This would be impracticable.

Nickel has been used as a base for diamondiferous cutters. Discs to act as slicers, crown-wheel-like face-cutters, and other forms of tools have been made in nickel and charged with diamond dust. These were patented in 1877 by S. Dessau, and I find some of them in my cabinet. They are directed to be used with water, and have been highly spoken of; but I have never used them. Nickel as the diamondiferous base would have the advantage of not rusting. Its homogeneousness and firmness of texture also make it eminently suitable for receiving and holding the microscopic diamond sparks.

**James Edmunds.**

Grafton-street, Bond-street.

---

[23913.]—I fear that our friends will not be satisfied with their work if they attempt to follow out the directions given to them (I am sure with the best intentions) by Mr. Wenham (23882), and although systems in use forty years ago may still be favourably looked upon by men of the old school, their results were unsatisfactory, and modern workshop practice is vastly different.

Having been engaged all my life in making the hardened steel ornamental lathe mandrel, I may perhaps supplement the directions given by Dr. Edmunds. His directions, which are perfectly clear and sound, are regularly in use for very fine steel work for the ornamental lathe in my factory in Norwich.

The Doctor, however, only deals with the trueing up of the hardened chuck bearing surfaces of a finished mandrel; but when the finest screw taps can be cut throughout with revolving cutters and finished with laps to a perfection never previously obtained with chasing tools, is there anything unpractical in finishing a mandrel nose by similar means, or can we do better than follow out what he has said?

If anyone tests the nose and face of a fine ornamental lathe mandrel, they will generally find both these and the portion upon which the pulley is fixed soft; occasionally, the face and nose in the hardening process get somewhat hard, but not to the extent of the sliding parts, which should be so hard that the corner of a new file will not mark them. The prussiate process which Mr. Wenham describes in his kindly-meant directions would only give a skin-deep hardening, which would be ground off before the usual amount of distortion could be cured, and yet this system is probably carried out by some lathe makers, for I have had to put new traversing mandrels and collars into comparatively new lathes which had proved inaccurate and unsatisfactory, and upon testing, these have been found perfectly soft in places, and having a kind of piebald appearance.

The chief reason why mandrels are spoiled in the hardening is because they are allowed to swag in the fire before they are chilled. Now, a lathe mandrel with its large collar put as Mr. Wenham describes in a U-form sheet-iron holder would be supported upon its collar at one end and its tail at the other, and when hot enough to harden, would probably be swagged down in the middle, and when chilled would be found to be bent. This bending, therefore, is not caused by the chilling, but by allowing it to be unsupported in the middle while soft and flexible; then again, the process described by Mr. Wenham would harden the mandrel in the portion upon which the pulley is fixed as well as at its slide bearings, and this would render it extremely difficult to key out and finish to fit the pulley. With the greatest care occasionally a mandrel will get hard a little too far towards its central portion, and this entails a considerable amount of grinding to perfect. The practical point in this hardening is that the mandrel should be bedded upon soft ashes for its whole length, and also be continuously turned while hot; the swagging while hot is fatal.

Mr. Wenham says: "Some of our best makers now prefer to true up their hardened steel mandrels by a diamond turning tool." This was the practice in our shops when I was a lad, and I have seen it done, but better work can be obtained by modern systems. Our traversing mandrels, made of the finest and best quality of cast steel, when bored out and hardened, are set up on dead centres with a temporary wood pulley upon them, and are slowly and continuously revolved while they are ground into shape by a dry emery wheel revolving at a very high velocity. This wheel must, as Dr. Edmunds observes, run very freely in its bearings, but without the least shake. Its surface also must be exceedingly true, or it will not produce good results. The secret in the circular saw is to have it turned up very true, so that all its teeth cut; each tooth then does its own work, and the saw cuts evenly, quickly, and easily; so it must be with an emery wheel—its cutting face must be positively true. Such wheels should be turned up with a diamond tool used similarly to a graver, and this is a purpose for which a diamond tool answers perfectly; but its use for trueing up large hardened steel surfaces is a mistake.

As to the final trueing up of the bearing, we do this upon the same principles as the Doctor described, using a copper wheel with crocus, and the last touch is finally given by working the mandrel into its bearing with a dash of crocus, washing it out quickly with oil immediately the practised hands of the workmen find it runs easily.

The trueing up of the hardened chuck bearing surfaces must be done after the mandrel is mounted in its own permanent bearing, and it cannot be done better than by the methods described by Dr. Edmunds. With such fine work of course the skilled mechanic feels his way, but he will never succeed unless he understands the principles of the method.

Mr. Wenham objects to the revolving cutter described by Dr. Edmunds on the ground that "every portion of the spiral in a screw increases in angle from the top to the bottom of the thread, and it is only a corresponding portion of a spiral, such as that in a chaser, that can touch the thread in every part." Surely this again is a mistake. The increasing sharpness of the spiral is just the same in cutting a screw with a single-point tool as with a revolving cutter, if only both have the same value given to them. Then, again, the copper chaser would have to be withdrawn and replaced continuously, like a hand chaser, and would totally fail to replace the revolving V-edged lap.

Perhaps Mr. Wenham did not see the model screws exhibited at the conversazione of the Amateur Mechanical Society by Dr. Edmunds. I venture to say that more accurate screws than those can hardly be produced, for their surfaces when viewed through a lens were most perfect.

While writing upon lathe matters, I desire once more to protest against the adoption as a standard lathe mandrel nose of the Whitworth thread with its rounded form, in place of the beautiful thread devised by Dr. Edmunds. These threads, known as the Whitworth standard, while answering every purpose for bolts and nuts, are only rounded off at top and bottom by rule of thumb, and as Sir Joseph Whitworth himself admitted, to suit the eye of a careful workman, each pitch requiring a different circle to round it down. It is, therefore, impracticable to make such a thread with exactitude, or to obtain the best results with it out of a cylindrical shell of a given size; and unless my clients order otherwise, I shall adopt the Edmunds thread from 50° truncated 7½ per cent. for all my fine screws.

Messrs. Whitworth and Co., under date of the 27th ult., have favoured me with the following data as to their lathe-nose threads, and as the information is not to be found in their list of screw threads, it will be of value to many readers of the English Mechanic. It must be recollected that the 6in. Whitworth lathe, light pattern, is their 5in. lathe, but with its headstocks and slide-rest an inch taller:—"In reply to your letter of the 25th, the pitch of thread, diameter of screw, and threads for the Whitworth lathe mandrels, are as follows—

| Height of Centres. | Diameter of Screw. | No. of Threads per inch. | Angle of Thread. |
|---|---|---|---|
| 5 inch | 1·25 | 6 | |
| 6 ,, | 1·375 | 5 | |
| 7 ,, | 2· | 4 | Average about 50° |
| 8·5 ,, | 2·25 | 4 | |
| 10 ,, | 2·5 | 4 | |
| 12 ,, | 3·25 | 3 | |

We do not make lathes except in very special cases below 5in. centres, and then the spindles are screwed with the Whitworth pitch of thread angle 55°."

I should be glad if Mr. Boord would favour us by saying when we may expect the decision of the Council of the Amateur Mechanical Society upon the standard mandrel head with its screw thread.

Griffin Works, Norwich. **Edward Hines.**

## STATE OF MAN.

[23914.]—It is rather difficult to make any comment upon the subject matter of letter 23874, p. 559, without straying into forbidden regions of discussion; but perhaps I may point out to "O. J. L." that the theory of a state of barbarism after expulsion from paradise is inconsistent with the Hebrew writings, for in Gen. iv. 17, we read that Cain "builded a city," a statement which cannot be reconciled with the hypothesis of a long relapse into savagery. Moreover, in v. 22, same chapter, brass and iron are mentioned, at a period only about 900 years after the creation of Adam.

**Wm. John Grey, F.C.S.**

Gateshead-on-Tyne.

## THE NEW TIME NOMENCLATURE.

[23915.]—The following appeared in the *Times* newspaper, 2nd March, viz.:—

"A New Clock.—A very interesting clock has just been fixed opposite the National Provincial Bank in Bishopsgate-street. It is on the 24-hours principle, and is remarkable as possessing probably the simplest method which has yet been introduced for indicating time upon the new enumeration. The new clock has only one hand, the long minute hand, and the figures around are placed as heretofore; instead, however, of indicating the hours, they indicate the minutes only, which are marked from five to 60. The hours are shown on a sunk dial revolving under the upper dial, a space being left in the upper dial in which the next hour figure comes forward instantaneously upon the minute hand completing its circuit of 60 minutes. In short, the solitary hand marks the minutes, and the sunk space shows the hour."

I happened to notice the clock to which allusion is made a few days back, remarking that it would be difficult to arrange any better principle for showing distinctly the time, according to the 24-hour nomenclature, *for large clocks*, but for watches I consider the hours from 13 to 24, placed on an inner circle, preferable.

An improvement in detail upon the clock-face mentioned above, would be to have the *hour figures* still larger than they are—there is plenty of room for this, I fancy.

There is a very large clock on the Piazza, at Venice, with the hours from 0 to 24 arranged around the circumference of the dial, with one hand to indicate the hour, the minutes being shown through a square opening just above the 12 in the lower part of dial, but the figures move forward instantaneously only every five minutes; so that the new clock, though similar in the ideal of its construction to the Venice one, is far superior in its operation.

**Gamma Sigma.**

## VIOLINS.

[23916.]—If I venture to revive a subject which many will doubtless think an unprofitable one, it is not with the intention of asking anyone to devise a new form of fiddle. When we read accounts of the fine qualities of tone attained by the old masters, are we to believe that every violin made by the Amatis, Stradivarius, and Guarnerius is an excellent instrument? Time may improve a good instrument, but it hardly seems likely that it will convert a bad fiddle into a good one. Notwithstanding that 150 years have elapsed since Stradivarius died, no one seems to have been able to improve upon his model. I am unaware whether any exact measurements of one of his instruments have been made. If any reader possesses such, I trust he will communicate it to these columns. It becomes interesting to investigate such matters, because there can be no doubt that the curvatures of back and belly are of very great importance. I seem to remember having read somewhere that the approximate curve of the belly lengthwise was a sphere of about 40in. radius, and crosswise about 5in. radius. But it appears to me that a sphere is altogether an unsuitable curve for such a purpose. I should judge that both should be catenary curves, that is, the same as a slack rope will assume when stretched between two supports. Now although this may seem a small matter, yet it must be of importance, because if the form of soundboard be such that it is irregularly affected by pressure, the vibrations will be interfered with and the sound diminished. I shall be glad to hear what other correspondents have to say on this matter, and if there be one amongst "our" circle of readers who has dissected a genuine fine old instrument, I hope he will give some account of its peculiarities.

**Orderic Vital.**

## MECHANICAL MATTERS.

[23917.]—I have to thank our good friend "J. H." for his kind compliance with my request respecting a set of engine patterns. When I have glanced down the sale columns, I have often thought how useful a series of constructive articles, such as those now commenced, would be.

In reference to the matter of lathe-mandrels, I would remark that it seems almost impossible for an amateur to construct a parallel mandrel, free and easy running, and yet without shake, if he uses a pair of hard steel collars. It is at once evident that unless the cylinder and collar fit perfectly in every part it will soon become shaky and unsatisfactory; and when once this happens, there are no means of adjustment to remedy the defect. Is it practicable to cast two pair of split bearings in steel in the same way as in brass?. If these were fitted and hardened, any after adjustment, if necessary, could be easily managed.

And with reference to the ordinary coned bearings, can it be shown that hard steel has any great advantages over good hard brass?

**Orderic Vital.**

Anhydrous Analysis.—In consequence of the author of letter 23887, p. 562, not having received proof in time, several errors escaped correction. On page 563, 12th line from bottom of first col., read "Inorganic" chemistry. In 14th line from top of 2nd col. read "volatility." In "Class 2, Division II." read "coloured black or white," and in the two following paragraphs, for fragments of boric acid, read "amorphous fragments in boric acid." In p. 564, 5th paragraph, read "top of the vertical sublimate," and "yellow while hot," and in 21st line, 2nd col., read "dioxydised" for deoxydised.

**Petroleum for Fire Engine Furnaces.**—It is proposed to substitute crude oil for coal for the working of the engines of the Fire Department in Brooklyn. Commissioner Poillon, Chief Nevins, and other officials witnessed an experiment of firing up an engine with the oil recently. The points of superiority claimed for the new plan is that steam can be raised up more quickly than with coal; that it is much cheaper than coal, a barrel of oil costing 1·60dol. and a ton of such coal as is now used, costing 4dol.; that as much heat can be obtained with one barrel of oil as with a ton of coal; that an engine can take to a fire enough oil to last five or six hours, while it can take but an hour's supply of coal; that with oil an engine will send out no sparks, and the running over of hose by supply waggons will be averted.

# REPLIES TO QUERIES.

**** In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[54825.]—**Salt.**—In the "E.M.," 24th October, 1884, p. 183, Dr. Allinson states regarding salt:—"Animals in a state of nature will not touch it, though some writers affirm that buffaloes go long distances to a salt lick. . . . Even if some animals will take it, we must not argue that they are right, for animals can and do make mistakes, like human animals." Now, I can assure Dr. Allinson that he is wrong in saying that animals in a state of nature will not touch salt; and also wrong in his supposition that animals that do take it get no good by eating it. I have been engaged in breeding and fattening cattle for the last twenty-five years (in hilly country quite 150 miles from the sea in a straight line), and can state positively that salt is absolutely essential to the health of both cattle and sheep, whether born and bred here, or brought here from other pastures. I use about four tons of rock salt per 1,000 head of cattle, and about 12cwt. per 1,000 sheep, per annum. Abstinence from salt has the effect of causing the stock to fall off in condition, and to become dry in the coat and hide-bound, all of which symptoms disappear when the animals can satisfy their craving for salt. The kangaroos, which certainly are "animals in a state of nature," greedily lick the salt put out on the run for the cattle and sheep.—HENRY SHARP, Green Hills, Adelong, N.S. Wales, 10th January, 1885.

[55049.]—**Powerful Opera Glasses.**—My last communication (p. 500) brought me correspondence with some 30 of our readers inquiring for these glasses. Upon orders going forward to maker No. 2 in Paris, he replied that he must raise the price of the 7-power instruments. Differing altogether with "Philoctetes," who says, p. 522, that high powers must necessarily mean high prices (the only difference between high and low power being small instead of large field, and high instead of low magnification, with the same light), I wrote to maker No. 1, who answered that he would put in hand at once a certain quantity of 7-power, as well as of 4 and 10-power glasses, to ascertain the lowest cost at which these three sizes can be respectively supplied. On receipt of the information I will advertise it on our front page. He assures me, meantime, that there will be, at any rate, no need to increase the price as his neighbour has done.—MONT-[illegible].

[55226.] — **Screw-cutting.** — Referring to "Valetta's" reply to "Glover" *re* screw-cutting in "E. M.," 28th November, 1884, page 290, I took his index to cut four threads to an inch, but could not have the wheels to gear. My leading screw is two threads to an inch, and number of teeth per wheel are from $\frac{1}{2}\frac{5}{0}$ increasing five each wheel. Any information will be very thankfully received.—YOUNG TURNER.

[55372.]—**Rotating Apparatus for Vacuum Tubes.**—If "D. C." will please refer to above number, p. 522 of "Ours," and will kindly furnish the desired information, he will greatly oblige, amongst others—J. W. S. L.

[55384.]—**American Organ.**—To MR. FLOYD.—I first removed a portion of the tube board to suit the length of the 8ft. reeds, and glued a mortise-board on the bottom. I then made mortises on top of the 4ft. tube board, between the end of the reeds and the plunger holes, and glued the board on. I found it necessary to put on the little mortise-board, as the tubeboard projected over the 4ft. row, and I could not fix it over the 8ft. row; as the space between end of tube and plunger-hole would be too short for the mortise, I left the reeds straight. The tone, though not so loud as the other rows, is clear and without harshness, and the reeds speak as promptly as the others. Do you know if there are any Munro reeds made of shorter scale than the ordinary ones? and would you kindly say what would be the best kind of reeds to use for an organette?—H. M. I. R.

[55487.]—**Hot-Air and Vapour Baths.**—I should like to ask if an atmospheric gas-burner could be used in the above baths without any ill-effects to the patient.—G. P. H.

[55520.] — **Condensation on Galvanised Roof.**—Kindly refer to advertisement columns.—T. P.

[55571.]—**Turbines.**—Thanks to "Essar" for his attention to above query. On referring to my former letter, I find I have not explained sufficiently. As I have but a small supply of water, I must, to increase my fall and power, excavate tail race to a depth of 30ft. My pond is about 15ft. over level of farmyard, and I shall then have a total fall of 45ft. I purpose setting turbine about 10ft. under level of farmyard floor, and having the remaining fall of 20ft. utilised by means of a draft tube of cast iron, 9in. in diameter, perfectly airtight above, and having its lower extremity sealed by the water of the tail-race to prevent the air from entering and liberating the water. Now here is my difficulty. All the authorities I have consulted agree in saying that a draft tube will work under above-mentioned conditions, provided that the draft tube is *placed perpendicularly*; but none of them will say positively that it will be equally effective when laid on an incline. Now, the water in a draft tube is governed by exactly the same law as the water in the suction-pipe of a common lift pump, and we every day see these last prolonged almost indefinitely, and lifting water from wells at great distances from the pump barrels. I myself can see nothing to prevent the draft-tube acting when set on an incline; but I fear that the air might get in at the glands of turbine and cause the water to leak off at bottom. To obviate this I thought of putting a valve at bottom of draft-tube, and then, should it leak away when standing still, I could by closing valve and opening sluice of turbine, fill all the tube again, as the air would escape to pond, the whole length of pipe being inclined. However, before completing the work, I should wish to know if any of the readers of our valuable journal have seen anything on the same plan at work.—E. F.

[55605.]—**Ritchie's Electro-Motor.**—In reply to "Gatton Park," I have referred to Prof. Thompson's book, and find that he does call Ritchie's magneto-electric generator a "motor"; but if the querist will refer to p. 530, Vol. XVIII., he will find that Mr. Ritchie himself describes it as a machine for producing current for working clocks. "The mere mechanical part of causing the armature to rotate in front of the magnet-poles might be performed by a weight or other motive power, and might be continuous, or started at regular intervals, by a governing clock." The number of the patent is 169, 1864, "Applying Magneto-Electricity for Propelling Clocks." "Four coils are arranged on soft iron polar extensions of a permanent magnet, and a keeper is rotated over them; or a disc wheel carrying small bars of iron is rotated before the poles of a permanent magnet." I presume the apparatus could be used as a motor, but that was not its purpose. I can find no other motor of Ritchie's.—NUN. DOR.

[55606.]—**Ritchie's Electro-Motor**—Consists in an electro-magnet poised on a pivot between the two poles of a permanent horseshoe magnet; the wires which are coiled round the pivoted electro-magnet dip into a circular trough, divided into two halves by a central partition placed in a line with the poles of the permanent magnet. This trough is filled on either side of the partition with mercury, and as each half of the trough is connected with opposite poles of the battery, it acts as a commutator.—S. BOTTONE.

[55689.]—**Marine Piston Speeds.**—I cannot tell your correspondent what piston speed was employed on the *Livadia*; but he may get at what he appears to want to know by remembering that it is very rarely indeed that the number of revolutions is less than 55 per minute, while in small vessels it often reaches even 200. There is no reason why with large engines a speed of 1,000ft. per minute could not be maintained.—ESSAR.

[55690.]—**Electro-brassing.**—Brassing by the galvanoplastic process is not an easy thing for any one without considerable practice; but the querist will find much information in Gore's "Electro-Metallurgy," Longmans. For coating castings of iron he may try the following:—Dissolve 2 parts of sodium bisulphite, 5 of cyanide of potassium, and 10 of carbonate of sodium in 80 parts of distilled water; add 1 part fused chloride of zinc and 1½ part of acetate of copper dissolved in 20 parts of water.—NUN. DOR.

[55692.]—**Sand Blasts.**—I think the sand blast patent has expired by efflux of time; but the querist will find details in back volumes, pp. 314, 437, Vol. XXVII.—NUN. DOR.

[55707.]—**Bessemer Steel Tires.**—This is to be done only by finding the sectional area, and multiplying that by the known weight of the metal in a given area. I think there are rules in Hoare's "Iron and Steel," pocket-book, published by Lockwood and Co., but cannot refer, because, like the Spanish Armada, the book is not in sight.—ESSAR.

[55723.]—**Gramme Dynamo.**—To S. BOTTONE OR "W. H. E."—Send me full details as to size and shape of your field magnets and armature, and what you require the machine for when done, and I will do my best to assist.—S. BOTTONE.

[55725.]—**Liquid for Hydraulic Machinery.**—The usual thing is to add about 20 per cent. of glycerine. I don't know where to find a table giving the freezing points of mixtures of water and glycerine.—E. T.

[55728.]—**Creasote Oil.**—The cheapest would be brick faced with cement; but I think iron would be better.—ANILINE.

[55736.]—**Legal Rights.**—This query can be answered only by referring to the Act incorporating or granting powers to the water company, whichever it may be. Companies of the kind have certain powers which enable them to compel customers to put in proper fittings, but exactly what they are depends on the wording of the respective Acts.—LIMB O' TH' LAW.

[55738.]—**Tinmen's Solder.**—By running the proper mixture at a suitable heat, tin solder comes out bright.—E. T.

[55752.]—**Legal.**—If you can prove that the property is yours, summon the person who refuses to give it up.—LIMB O' TH' LAW.

[55753.]—**Flywheels.**—I have looked up this flywheel, and don't wonder that it passed with "little notice." It consists in arranging some tubes so that mercury would shift its position as the wheel revolved. If "Norfolk" thinks that a flywheel weighing cwts. can do the work of one weighing tons, he must have altogether failed to grasp first principles.—ESSAR.

[55760.]—**Blow-off Pipe.**—I am not aware that boiling water is more resisted by the atmosphere in its outflow than cold water, and can only suggest that the difference mentioned by "Yama" arises from a fall of pressure in the hot cylinder. The formula I gave assumed that the pressure was constant.—WM. JOHN GREY, F.C.S., Gateshead-on-Tyne.

[55785.]—**Locomotives.**—Many thanks for the replies of "Invicta" and E. Gobert, B.Sc. The information has been of great service to me. There is, however, one point I observe in the numerous experiments recorded in "Railway Machinery," no mention is made of the depth of fuel corresponding to the recorded draught. On this account the experiments seem to me to be somewhat defective. I notice in a chapter on the combustion of fuel in a recent edition of Rankine's "Steam Engine," mention made of a method of firing boilers which has been in use in France, and is called the "Système Beaufume." Any information about this will much oblige.—ASTERISK.

[55794.]—**Gas Tanks.**—As a lime-light operator in country theatres, using gas bags, I am considerably interested in this query, and in connection therewith I should like some information respecting a statement in Chadwick's "Lantern Manual." It refers to a gas tank of special construction. The pressure was applied by water from a ball-tap cistern, and conveyed to the inside of the holder by a pipe. The end of this pipe dipped into a vessel of water placed in the upper part of the inside of the holder, and from it was an overflow pipe conveying the water to the bottom of the holder. The author states that the pressure was due to the difference in height between the surface of water in the cistern and that of the vessel within the tank, and that, however much or little gas was in the tank, the pressure was constant. Is that so? Is not the pressure due to the difference between surfaces of water in holder and cistern?—CUIDADOSO.

[55798.]—**Stove.**—Kindly refer to advertisement columns.—T. P.

[55801.]—**Smith's Bellows.**—To "INVICTA."—A circular bellows would be made in a way very similar to that already given by me, with the exception that the wood part would be circular instead of oblong. In practice I cannot say I like the circular form so well as the oblong. As you desire it, I append a rough sketch showing on

FIG. 1.

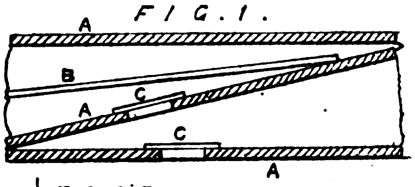

FIG. 3

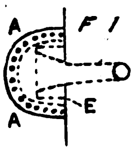

FIG. 2.

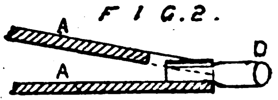

Fig. 1 bellows in section; A A A are the flue boards; B, one of the four stretchers; C and C the air valves; Fig. 2 shows how the blastpipe is secured to the reservoir. It will be seen that the pipe is flattened, so that it has less height. This is then made up with a piece of wood cut to fit it so that it stands up square. The top board A is cut away as shown, to allow this to be done, whilst E, Fig. 3, shows the apron piece. This being well nailed round the edge and over the lap, makes a simple and tight joint. It must be, of course, nailed on when the reservoir is empty, or it would be likely to prevent it fully closing. Weights placed on the upper board, and well secured there, regulate the force of the blast. I trust the sketch, rough as it is, will make all clear to you. If not, I am still at your service if I can help you.—Invicta.

[55802.]—**Silos**—I have never seen a silo without sides of some kind, either walls of brick, stone, or concrete, or else boards. When boards are used, or even when the walls are not smoothly plastered, the air will enter, either through the joints or down by the rough sides of the walls, and cause some of the ensilage to mildew. I have seen a very simple means of applying pressure. In the main it is the same as that described by "Tredagh" in the "E.M." of Feb. 13th; but in lieu of two screw-jacks a cruciform forging is used, having the two opposite ends screwed, the one right-handed, the other left-handed. These screws are furnished with nuts and hooks, to which the chains are attached, and the main bar is then twisted round by means of the cross arms, and the nuts and chains are drawn together; consequently, the ensilage is compressed. I believe the article is patented. Messrs. Carson Bros., 21, Batchelors-walk, Dublin, are the manufacturers.—E. F.

[55815.]—**Boat.**—Fig. 1, p. 373, Vol. XL., is a rough drawing showing the manner in which the boat should be designed. The left side of the figure commences amidships and shows the curve aft, ending at the transom; the right side also begins amidships and shows the curve forward both from gunwale to garboard strake. Should "Nero" require further assistance, write again stating particulars of the boat he intends to build, and whether a rowing boat or small yacht.—James McCash Govan.

[55826.]—**To "Invicta."**—Thanks for your kind answer and offer of circular, to obtain which I have advertised my address.—Jay Jay See.

[55827.]—**Gravity and Dead Escapements.**—The "Country Parson," who asserts as dogmatically and courteously as if he were in that place where he is safe from contradiction, that "Sir E. Beckett is distinctly wrong in stating as he does that clockmakers charge less for making the gravity escapement than the dead-beat," is himself distinctly wrong in both ways. For, first, I have never said so; and, secondly, what I have said is distinctly and simply true—viz., that Mr. Brock has never charged me or anyone that I know of for a four-legged gravity escapement regulator, with pendulums up to 40lb. weight, more than half of what I know used to be, and I suppose still is, the price of the best dead-escapement regulators with only 12lb. pendulums (p. 127 of 7th edition). He is no less wrong in saying that I do not sufficiently recognise the distinction between the suitability of the gravity escapement for turret clocks and regulators. Not that "suitability" is the right word; for the four-legged gravity escapement is equally "suitable" for regulators and for small turret clocks, and the double three-legs for large ones, though the superiority of the gravity escapements is, one may say, infinitely greater for turret clocks. For regulators which have nothing to do but mere going—no striking or electrical work—I do not think there is any material difference between the four-legged gravity, my five-legged single-beat impulse (p. 106), Sir G. Airy's single-beat one (p. 105), and a good jewelled dead escapement, with a fine train.—Edm. Beckett.

[55843.]—**Photo-Micrography.**—To "Invicta" and Mr. Bottone:—I have put into effect your suggestions, and have used the ferrous developer. The yellow stain is gone from my plates, but the film is extremely thin. After intensification in the ordinary way, the contrast between black and white is too marked, and the negative is useless for printing a positive from. Has the light I use anything to do with the failure?—John Carrington.

[55870.]—**Optics with the Lantern.**—I am much obliged to L. Wright and W. Shrubsole for replies to my query. The latter does not quite understand why I cannot get lime near enough to condensers for parallel beam. It is because the curved part of jet strikes against condenser itself when pushed up. I have failed to get a blow-through jet which can be placed close enough. One would think there should be no difficulty in doing so. Are jets never made as in Fig. 1, instead of like mine, Fig. 2? I find I did not make query (2) plain to Mr. Wright. I proceed as follows:—I find where rays cross, after passing through loose lens, by means of smoke, and place my prism at this point. Result—a most feeble spectrum. I then try, by placing prism close to loose lens, to get very fair spectrum. This is what I do not understand; especially as in latter case much light falls outside prism (and is screened off by black card fitting close round prism), and is therefore lost. Can Mr. Wright help me, and also tell me focus of cylindrical lens he uses, and how it is fixed? I suppose it is placed in lantern front, just between condensers and slit. I do not understand answer (3); surely a longer jet would render it less possible to push lime up close to condensers—not easier.—S.

FIG.1.

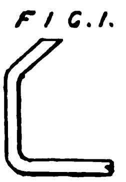

FIG.2.

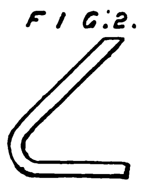
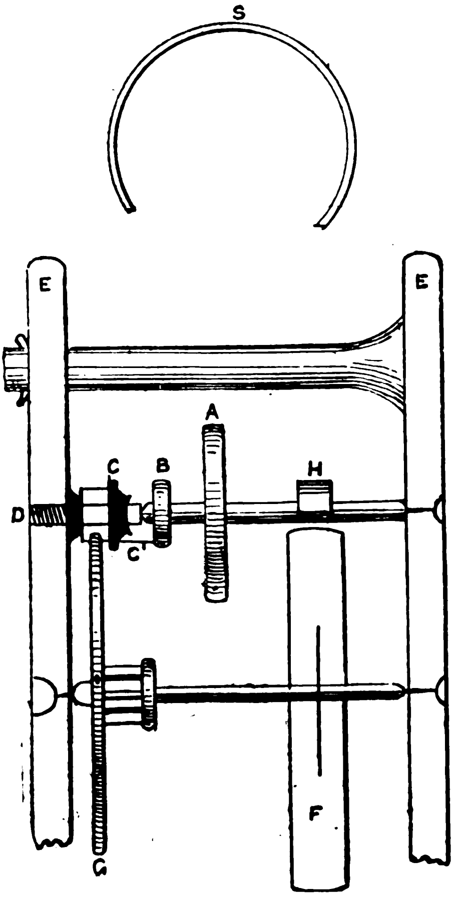


[55876.]—**Improving Light of Coal-Gas.**—At the Health Exhibition last year there was exhibited by the Omega Gas Light Company a lamp in which the illuminating power was increased by the gas passing through a carburetter. The burner used was for a consumption of 2½ft. per hour, giving, with ordinary gas, an illuminant of four candles; but this was increased by the carboleine arrangement to 17 candles, at an expense of less than a farthing for three hours' consecutive burning.—T. K. W.

[55884.]—**Fixing Clock Wheel.**—Either turn the pinion down at one end to fit hole in wheel and rivet, or drive piece of brass on arbor and treat same way. If you do not understand this, write again, and say where you want wheel fixed on pinion or plain arbor.—Noterom.

[55885.]—**Silvering Graduated Dial.**—If the graduations are not engraved you must have them painted after silvering; if engraved, silvering should not alter them.—Noterom.

[55887.]—**Altering Clock.**—The sketch below is taken from Sir E. Beckett's book which, I think, is what "Clockey" wants. A is the 'scape wheel, mounted firm on a staff; B, the mainspring (watch) which drives it; C is a brass plate riveted on to the pinion with a carrier (C') fixed firmly into it for the purpose of clamping the end of mainspring. This pinion is hollow, and runs on a foot (D) screwed into the plate E, the foot is a little longer than necessary; for the purpose of receiving a bushing for the 'scape pivot. F is a fan or fly fixed stiffly on to the second wheel G. This fan has one side longer than the other, so that the short side will pass the boss H mounted on the 'scape arbor; P, the long side, will fall against it. I just send the above, as "Clockey" desires it, though I would not advise him to go to the trouble of altering his turret clock. I think if he looks to his hands and gets them as close as possible to the dial, also sees that the minute hands are well and properly balanced, or if he will go to the trouble of putting a deep moulding all round his dials with the exception of the bottom, as per sketch S, it would improve matters by keeping the wind from playing on the hands.—Annie.



[55926.]—**Indicated Horse-Power of Launch.**—

Area of piston—

$$= \frac{22}{7} \times \frac{64}{4} = 50\ 3 \text{ sq. in.}$$

Travel of piston per min.—

$$= 300 \times \frac{16}{12} = 400\text{ft. per min.}$$

Load on piston—

$$= 100 \times 50{\cdot}3 = 5{,}030\text{lb. per sq. in.}$$

Indicated horse-power—

$$= \frac{5{,}030 \times 400}{33{,}000} = \frac{2.012}{33}$$

$$\therefore \text{I.H.P.} = 60{\cdot}9$$

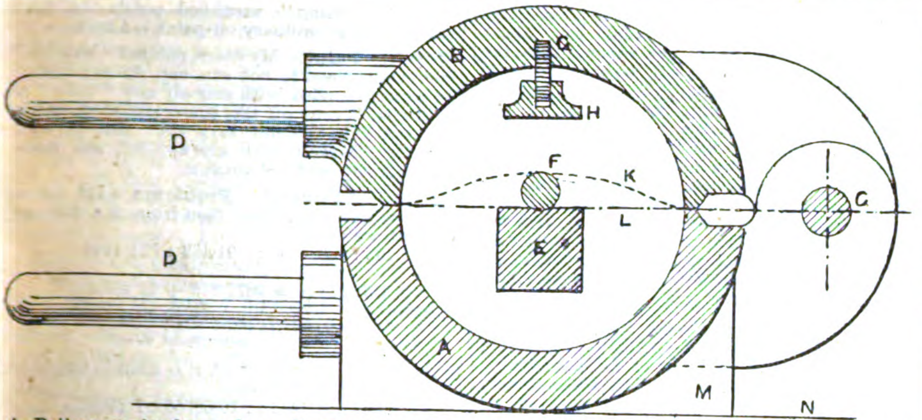
Not having the *Engineer* of Oct., 1879, or "Burgh on the Indicator," I cannot work your sum by their rules; but the above is the ordinary rule given in the textbooks. What do you mean by "300ft. piston speed"? If the No. of revolutions is 150 per min., the piston speed is 400ft. per min.—Weiv Revir.

[55930.]—**Watch Winding.**—In these so-called perpetual-winding watches there is an arrangement which acts somewhat like a pendulum, except that the ball of pendulum rises and falls at a right angle to the bow or pendant, the weight of the ball is nicely counterbalanced by two springs, so that the least motion of the wearer sends the pendulum up and down, and slowly winds up the watch in that way; that is the object of having the bow made in a peculiar shape and rigid, so that the watch will always remain in one position when worn, 12 hours or (24, I believe, now) upwards. As soon as you purchase a watch of this description it has to be wound with a key, then you are supposed to walk three miles per day, and your watch will be wound for the night; if you remain a day in bed your watch will run down. They are no better timekeepers than ordinary watches. If you wish, I will forward a sketch.—Annie.

[55932.]—**Plating Dynamo.**—Thanks for replies. Mr. P. Ward's proposal will not exactly suit. I trust Mr. Bottone will give me further information. The F.M.'s are of a very heavy pattern, and contain a considerable amount of residual magnetism, and upon rotating the armature it gives off 15 ams. and 1·5 volt, and deposits splendid copper and hardly makes any difference to the engine (a 1 h.p. Tangye gas); but when I switch the current through the F.M. coils and arrange the resistance to pass 15 ams., the E.M.F. rises to about 12 volts, and visibly slackens the engine, and, of course, I burn more gas and do not deposit any more copper. 15 ams. is not near enough for my purpose; hence the query. In the mean time will try slower speed; am at present running 1,500 revs. per min. for 13 hours per day.—Volt.

[55935.]—**Electro-Chemical.**—In his reply to this query, Mr. P. Ward mentions a current having "several million volts pressure, with about 0·2 ampères quantity." I would like to be informed how he obtained this current, which, taking "several" to mean only 34, represents over 1,000 h.p.—Wm. John Grey, Gateshead-on-Tyne.

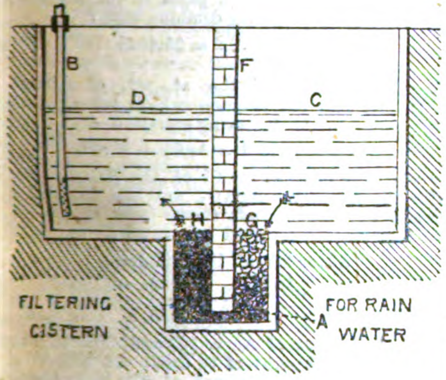
[55905.]—**Cores.**—Cast-iron pipes for gas and water mains have been made in Glasgow for a considerable number of years back with dry sand cores. They are cast on a declivity of 10 to 15 degs. in green-sand moulds with dry sand cores, and made from ¾in. diam. by 4ft. 6in. long, up to 7in. diam. by 9ft. long, and by one founder I know they are made as large as 12in. diam. by 9ft. long. I send you sketch of cross section of corebox, which is drawn about 3in. to 1ft. These core-boxes are of cast iron, in two parts, with hinge joints and handles; each of the two parts is planed on face and the half circles; they are afterwards clamped together and bored truly cylindrical from end to end, the part for socket being, of course, bored to a larger diameter. The cores are made as follows: Place the box on a table, fold back the top part and fill both with sand, lay in the core-box, which has previously been well coated with thick clay-water, into the bottom part on top of it; place round smooth pricker rod for vent hole, adjust screwed chaplet, add socket in top part, scrape sand in top part flush, and in bottom part rounded with a hollow scraper; brush joint clean, pull over top part with a "clash," ram up ends firmly, withdraw pricker, strike top part at several places with wooden mallet, open top part leaving core complete in bottom part; adjust chaplet to thickness of pipe, lift core gently by both ends and lay it over blackwash trough and take a tin can with small hole in bottom and fill it with blackwash and allow it to stream on core all the way along, and the core is ready for the drying stove. The core bars used are of square malleable iron, for a 3in. pipe ⅞in. square, and for a 6in. pipe 1¼in. square, and other sizes in



A. Bottom part of core-box. B. Top part of core-box. C. Hinge joints two or three in length. D. Handles for opening—two top, two bottom. E. Core bar of malleable iron. F. Pricker rod for vent hole. Q Screw nail chaplet, one in middle of length. H. Socket for chaplet. K. Line that sand is scraped to in bottom part. L. Line that sand is scraped to in top part. M. Webs for supporting core-box 3 or 4 off. N. Table about 2ft. 6in. high.

proportion, the bars for 9ft. pipes being about 11ft. long. With ordinary care the core is not appreciably oval, and is certainly the best and cheapest core for this kind of work. I am afraid the Editor will object to my going more fully into detail.—ASTERISK.

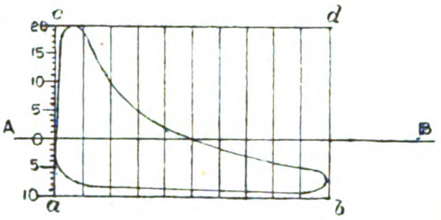
[55938.]—**Rain Tank.**—The most simple plan I know of is that shown in sketch. In this the filtering chamber is dug out below the cistern proper, and a brick wall (F) built from the centre of it to the top of cistern; the bottom of wall being arched to allow the water to pass. The filtering medium is arranged as follows:—The lower part of the chamber is well packed with *coarse* charcoal to the height of A; above this, on the side marked G, is placed fine well-washed gravel, which becomes coarse as it reaches the top of the chamber. The other side (H) is then filled with small charcoal, well rammed down. This completes the filter, which acts on the principle of the "ascension" filters, that being, I believe, about the best system. To return to sketch. The unfiltered water is stored in the side of cistern marked C, and filters through till at the same height in D. In the latter I have shown the position of supply-pipe (B) of pump. Can give further particulars if this description is not clear enough.—CHEMICUS.



[55939.]—**Legal.—Attaching a Patent for Debt.**—"B.Sc., Plymouth," is wrong. The sheriff can seize and sell a patent the same as a bale of cotton. In the case of the sale of a bale of goods the sale is perfected by delivery. In the case of the sale of a patent the sale is perfected by an assignment from the sheriff, to be, of course, registered at the Patent Office.—Z. Y. X.

[555941.]—**Refining Silver.**—"Nitrate" can separate his copper from his silver in the following manner:—Dissolve your silver in nitric acid with a little water; when all is dissolved add common salt till no more white precipitate falls down. The ppt. is chloride of silver, and the remaining liquid will contain nitrate of copper and nitrate of sodium. Then wash ppt. in filter, put into a crucible with some carbonate of soda and melt; the heat must be high enough to melt silver. The metal that results is pure silver. Redissolve this silver in weak pure nitric acid to form nitrate of silver.—J. K. S.

[55943.]—**Indicator Diagram.**—You must first ascertain the strength of the spring of your indicator; then suppose the figure (which is not drawn to scale) to represent your diagram in which A B is the atmospheric line, divide *a b*, the length of the stroke, into a convenient number of parts, say 10. Again, suppose, at cut-off, your spring indicates 20lb., divide the vertical line *a c*, so that the part above A B may contain 20 parts. Now, to get the mean pressure throughout:—At each intersection of a vertical line with the curve above and below the atmospheric line, draw a horizontal line to intersect *a c*. This will give the pressure at each division, giving in all 10 pairs of readings, those above and those below A B; adding these together and dividing by 10, we get the mean pressure.—WEIV REVIR.



[55943.]—**Indicator Diagram.**—I have not time to trouble our editor with a sketch; but the following will be found a most ready and most correct method of finding the I.H.P. Divide length of diagram into ten equal parts by vertical lines. Take a narrow slip of paper, say 7in. length, move it along the diagram, carefully marking off the length thereon of the whole nine vertical ordinates. Now, for instance, suppose they occupy a total length of the slip equal to 6¼in.; then this length must be multiplied by the scale per square inch, as found stamped on the indicator spring; divide the product by 10, and result equals the mean pressure per diagram. Disregard the atmospheric line in this instance.

$$\frac{\text{Area of piston in sq. in.} \times \text{mean pres.} \times \text{ft. per min.}}{33{,}000}$$

gives the I.H.P.—YAMA.

[55947.]—**Pressure of Water in Pipe.**—Though this is addressed to Mr. Davies, I may be permitted to say: A simple rule for the pressure of water in pipes is the following—For every 7ft. of head there is approx. 3lb. per sq. in. pressure; for accuracy add 1 per cent. to the result. 25ft. head gives pressure of 10⁵⁄₇lb. per sq. in., or, at lowest point, there is press. of $10\frac{5}{7} \times 1\frac{43}{56}$ = approx. 19lb. Suppose you have head of 12ft.:—

| | | | | | |
|---|---|---|---|---|---|
| For a | ½in. pipe | press. is | | 1lb. | approx. |
| ,, ,, | 1 in. | ,, | ,, ,, | 4lb. | ,, |
| ,, ,, | 1½in. | ,, | ,, ,, | 9lb. | ,, |
| ,, ,, | 2 in. | ,, | ,, ,, | 16lb. | ,, |
| ,, ,, | 2½in. | ,, | ,, ,, | 25lb. | ,, |
| ,, ,, | 3 in. | ,, | ,, ,, | 36lb. | ,, |
| ,, ,, | 3½in. | ,, | ,, ,, | 49lb. | ,, |
| ,, ,, | 4 in. | ,, | ,, ,, | 64lb. | ,, |

If you require the longitudinal bursting press. per inch of length, multiply the diam. in inches by the press. per sq. in. Knowing the diam. of the pipe, you find its sectional area, which call *s*; knowing the diam. of the pipe, you find its periphery, which call *c*; measure the length of the pipe, which call *e*; call the head of water, *h*. The discharge in cub. ft. per sec. is equal to $Q = S \times 100 \sqrt{\frac{h}{c} \times \frac{s}{c}}$ — $\frac{s}{c}$ is called the hydraulic mean depth. Suppose the pipe flowing full and its diam. 1in., let $h$ = 25ft. and $l$ = 100ft., $s = \frac{11}{14}$ sq. inches, $c = \frac{22}{7}$in., $\therefore \frac{s}{c} = \frac{1}{4}$ and $\frac{h}{c} = \frac{1}{4}$, $\therefore Q = \overline{\frac{11}{14} \times 100 \times} \frac{1}{4} \times \frac{1}{144} = \frac{1}{8}$ cub. ft. per sec. approx. = about 5 gallons per min.—WIEV REVIR.

[55951.]—**Visibility of Stars.**—The cause of the stars not being visible so low down towards the horizon as the sun and moon, is because their light is not capable of penetrating the stratum of air that is resting upon the earth (for this stratum of air having to support the air that is above it, it is more dense, and it has a pressure of 15lb. to the square inch). When the stars have risen 14° above the horizon, they become visible because we are looking through an atmosphere that is not so dense, and the higher they get the plainer we see them, and when we look at them immediately over our head, we are looking through an atmosphere of various pressures; that near us is 15lb., while that higher up gradually decreases to nothing. Therefore if there were no air upon the earth we should see the stars as low down towards the horizon as the sun and moon; but if the air had a pressure of 15lb. to the square inch throughout, we should never see the stars, while the sun and moon would always appear as large as they do when they are rising and setting because a dense atmosphere magnifies their diameter, and it is a fact well known that what will magnify one thing will cause another to become totally invisible. Therefore, as the stars cannot penetrate horizontally the stratum of air that is resting upon our earth, they must be invisible.—STAR-GAZER.

[55958.]—**Electro-Magnet.**—No. 24 B.W.G., s.c. will do very well, and the thickness of wrapping you mention is right. For quick-action magnets, short cores and more wire is better, as there is less residual magnetism; two Bunsens would be ample. Be very careful to have your cores very well annealed.—J. K. S.

[55969.]—**Problem.**—In hydraulic tables we find the following formula for the discharge of water from an orifice with a constant head of water—

$$Q = 8{\cdot}025 \,.\, c \,.\, a \sqrt{h}.$$

Where Q is the number of cubic feet in a second that pass through the orifice, *a* is the area in square feet of the orifice; *h* is the head of water or depth from surface of water to orifice in feet, and *c* is a constant depending on the nature of the orifice. For a circular hole in a flat plate it will be ·618. Our problem being to find in what time a cylinder of certain dimensions will empty itself, the head of water *h* will be constantly varying. Suppose the area of the horizontal section of the cylinder is A, and suppose the depth of water, or *h*, to be divided into thin layers, each $\triangle h$ in depth, $\triangle$ being a small fraction of *h*; then $\triangle h \times A$ will be the contents of each layer. Then as Q is the number of cubic feet that flow in one second, $\frac{\triangle h\, A}{Q}$ is the number of seconds that each layer will require to empty itself, or instead of Q, put its value given above in the formula in terms of *h*, and, for shortness, we will lump up the contents and call them M, so that $\frac{A \triangle h}{M \sqrt{h}}$ is the time that each layer will take to empty itself. By giving various values to *h*, according to its corresponding layer, and adding the results from last expression, we could get an approximation to the time that the whole barrel takes to empty itself; but this can be done exactly by the integral calculus. If we suppose the layers to become infinitesimal, then $\triangle h$ becomes $d\,h$, and the whole time occupied in emptying the barrel will be $\frac{A}{M}\int_0^h \frac{d\,h.}{\sqrt{h}}$ Now the integral of $\frac{d\,h}{\sqrt{h}}$ is $2\sqrt{h}$, t expression therefore becomes $\frac{2A\sqrt{h}}{M}$ If, therefore, we substitute in this the values of A and M, and make $h$ = depth of water when the barrel is full, we shall get the number of seconds it takes to empty itself. A curious fact will be found from the above. If we substitute the value of M in terms of Q obtained from the original formula, or $\frac{Q}{\sqrt{h}}$ in the last expression, it becomes $\frac{2A\,h}{Q}$. Now A *h* represents the contents of the cylinder when full, and as Q represents the number of cubic feet that flow through the orifice with a constant head *h*, then $\frac{A\,h}{Q}$ would represent the time that the barrel full of water would pass through if the height of water were kept up to its original level; but as our result is $\frac{2A\,h}{Q}$ it takes just twice the time for the same quantity of water to flow away when the barrel is allowed to empty itself without being replenished. If the barrel were cone-shaped, apex at the outlet, the time would be represented by $\frac{6\,A h.}{5\,Q}$—M.I.C.E., Bath.

[55969.]—**Problem.**—The contents of the vessel $= \cdot 7854\, h\, d^2$ cub. feet. Assuming the bottom of the vessel to be of inappreciable thickness, $h =$ height from surface of water to c. gr. of opening. Now, the veloc. in feet per sec. $= \sqrt{2\,g\,h} = 8{\cdot}024\sqrt{h}$. Sectional area of hole $= \cdot 7854\ x^2$. Now, call contents of vessel Q, veloc. of issue $v$, sectional area of hole S; we have—

$$Q = \cdot 7854\ .\ h\ .\ d^2 \text{ cub. feet}$$
$$S = \cdot 7854\ x^2 \text{ sq. in.}$$
$$v = 8{\cdot}024\sqrt{h}$$

Let $t$ = No. of seconds in time of discharge
$m$ = a constant less than 1 to be multiplied by result, its value depending on the form of opening. In this case, assume it
$= \cdot 62$

$$\text{Now, } Q = m\ .\ \frac{S}{144}\ .\ v\ .\ t$$
$$\therefore t = \frac{144 \times Q}{m \times v \times S}$$
$$= \frac{144 \times \cdot 7854 \times h \times d^2}{62 \times 8{\cdot}024\, h^{\frac{1}{2}} \times \cdot 7854\, x^2}$$
$$= 29\ h^{\frac{1}{2}} \times \frac{d^2}{x^2}$$
$$\therefore t = 29\ .\ h^{\frac{1}{2}}\ .\ \frac{d^2}{x^2} \text{ seconds—approx.}$$

—WEIV REVIR.

[55969.]—**Problem.**—

Let A = 95 sq. in., area of cylinder.
$a$ = 7·068 sq. in.. area of hole in bottom.
$h$ = 60in., height of cylinder.
$t$ = time of emptying, in seconds.
$g$ = (32·2 × 12) = gravity.

Taking the *vena contracta* at ⅝, the effective area of the hole becomes 4½ sq. in. Then—

$$t = \frac{A}{a} \times \sqrt{\frac{2\,h}{g}} = \frac{95}{4{\cdot}5} \times \sqrt{\frac{2 \times 60}{32{\cdot}2 \times 12}}$$

gives $t$ as 12 seconds. Can "Mechanic" test his cylinder and give us the result?—YAMA.

[55969.]—**Problem.**—When water flows from a circular hole in the bottom of a tank, the velocity of stream is ·594 of the theoretical velocity due to gravity. The discharge from an opening in the bottom of a tank is derived from the ordinary formula, $V^2 = 2\,f\,s$, when the head of water is constant. Thus, $V = a\,C\sqrt{2\,g\,d}$ gives the discharge in cubic feet per sec., when $a$ = the area of opening in feet, and $d$ the depth or head of water, C being the coefficient ·594. Now, the time of discharge of a tank from which supply is cut off is double that when the supply maintains a constant head. Hence, if A = the cross-section of tank, we can find time of discharge through the opening by dividing the volume of the tank by the volume discharged through the opening per sec.; that is to say—

$$t = \frac{2\,A\,d}{a\,C\sqrt{2\,g\,d}}$$

Substituting the dimensions given in the question for corresponding terms in this formula, we derive—

$$t = \frac{d^2 \times 2\,h}{x^2 \times \cdot 594 \times \sqrt{64{\cdot}4 \times h}}$$

—GEO. A. WALTON.

[55969.]—**Flow of Water.**—Let A be area of the vessel, $a$ the effective area of the hole, $h$ the height of the water, A the time for outflow in seconds, and $g$ = as usual, then

$$A = \sqrt{\frac{2\,A^2\,h}{a^2\,g}}\ ,$$

By effective area is meant the area of the hole, allowing for the *vena contracta*. This area may be as high as ·946 of the actual opening, or as low as ·5 thereof. If the hole is a mere opening without any ajutage the coefficient is ·625. It may be mentioned that if the hole is exceedingly small, so that the ajutage is a capillary tube, then Torricelli's theorem no longer holds.—WM. JOHN GREY, F.C.S., Gateshead-on-Tyne.

[55971.]—**Twist Drills.**—The chuck will hold them firmly enough if you screw the jaws up tightly. I suspect you are afraid of breaking something. Try again. Don't waste time in endeavouring to shape the drill.—C. D. R.

[55974.]—**Gasoline for Gas-Engine.**—If you refer to some recent replies, you will, I think, find the best proportions given. The simplest way would be to pass the air and gasoline vapour through orifices of a known size, so that a constant relation of one to the other would result. There is to this plan an objection that any increase from the normal speed on which the calculation was based for the apertures would vary the proportions. A great variation of proportion would bring about its own cure. If too much gas vapour, then the engine would not work at all, neither would it work if the vapour were too dilute. If the cylinder is as strong as the Bischopp, for instance, or, say ½in. metal for a 5in. to 6in. cylinder, you never need fear a burst by the use of a very strong charge. No charge you could fire in such a cylinder would rupture it. On what plan are you proposing to make a gas-engine? I have often, when discussing the question, wondered why for small powers the oscillation cylinder form has not been used. As the advertisement pages will show, the oscillation cylinder is used for steam and water pressure. Then why not for gas?—INVICTA.

[55976.]—**Metallurgy.**—On heating argentic sulphide with free access of air it is converted into metallic silver with evolution of sulphur dioxide. A small quantity of argentic sulphate is also usually formed.—WM. JOHN GREY, F.C.S., Gateshead-on-Tyne.

[55977.]—**Diameter of Driving-wheel of Locomotive.**—The driving-wheel diameter of the Liverpool, built in 1849 by Bury, Curtis, and Kennedy, of Liverpool, for the L. and N.W. Railway, was 8ft. The Great Western had some engines built by Hawthorn in 1838, of which the driving-wheels were 10ft. in diameter, and in these the machinery was put on one carriage and the boiler on another. They proved entire failures; one of them, Ajax, had only 474ft. of heating surface.—B.

[55977.]—**Diameter of Locomotive Driving Wheel.**—The Liverpool had 8ft. driving wheels. They were the trailing pair. The largest size ever used on the G.W.R. was 10ft., an engine called the Hurricane, built by Hawthorn in 1837. The big wheels and machinery were on a separate carriage from the boiler. The machine was an utter failure.—W. B. P.

[55978.]—**Tallow in Loco. Boilers.**—The greatest evil arising from its use is the liability of the furnaces to collapse; hence the general rip-up of the boiler. Tallow does afford a slight resistance to incrustation; but in doing this it also acts upon the iron, reducing its strength by local pitting. Do not use tallow; several evils arise from it, and numerous accidents are recorded and ascribed to its action.—YAMA.

[55988.]—**Cast Net.**—"T. E. L.," write to me, at Pitcairn's Library, King's College-road, N.W., and I will tell you all about it.—J. K. P.

[55988.]—**Cast Net.**—If economy is any consideration I should advise you to write to some firm, such as Hounsell and Co., Bridport, or look up catalogue of Fisheries Exhibition. But if intent on making yourself, use 6lb. thread; this is as strong as 9lb. twine and much lighter. The lighter the net the quicker it sinks. My cast net has a mesh of ¾in. at top and ½in. at bottom, there being several gradations between the two. A minnow net would require to be smaller in the mesh. The size of net must depend on your skill in casting; mine is 12ft. in diameter.—GEO. A. WALTON.

[55990.]—**Lubricators.**—Has "Belgian" never seen such a common thing as the small lubricator? They are small tin cans, generally about 3in. high, and about 2½in. in diameter at the bottom, and tapered up to ⅜in.; a small brass socket with a thread in it is soldered in at the top for the purpose of screwing a spout in—spout about ¾in. long with a bare 1-16in. hole down it to emit the oil. They cost but a few pence.—VALETTA.

[55991.]—**Screw-Cutting.**—There seems to be but one remedy, and that is to get a larger set of wheels. It is possible that the slots in the quadrant could be lengthened. If that would allow the quadrant to rise higher, then that is the course I would advise you on; or, if you could conveniently gear in two intermediate wheels between the mandrel wheel and the stud wheel, that would do. If it is only for one thread that you experience difficulty in gearing the wheels, remedy it as above, if possible; but if it is for several threads, I advise you to get a new set of wheels with a coarser pitch.—VALETTA.

[55993.]—**Screw-Cutting.**—"L. W." must make a square-thread tap on his lathe of the diameter and pitch required, and then the rest will be easily done.—GEO. A. WALTON.

[55993.]—**Screw-Cutting.**—Have you tried to fix your job anywhere on the saddle, and your tool in a chuck, so that the tool revolves instead of the work. If not, try it at once; but if that is impracticable, the only alternative I know of is to cut your thread with a tap.—VALETTA.

[55997.]—**Paint.**—If the shop-front is exposed to much sun, any dark-coloured paint is likely to blister. I should not, therefore, condemn the painter. In sunny positions I have found that paint stands much better when done in late autumn than in spring or summer, as it then has time to harden before the summer sun attacks it. I think also that "flatting" varnished resists the sun's heat better than ordinary oil-paint.—ACIER.

[55997.]—**Paint.**—My doors, painted "invisible" green, are exposed to hot sun and do not blister. The paint is applied with scarcely any "body" in it; in fact, it runs off the brush almost as readily as water. The painter says that this prevents blistering. Several coats are applied, and sandpaper is freely used.—ARCANUM.

[56000.]—**Chemical Problems.**—Let $x$ = atomic weight of chlorine; then from the first experiment we have—

$$108 : 108 + x :: 91{\cdot}462 : 121{\cdot}4993$$

and—

$$13121{\cdot}9244 = 9877{\cdot}896 + 91{\cdot}462x$$

whence—

$$x = \frac{3244{\cdot}0284}{91{\cdot}462} = 35{\cdot}46.$$

In the second experiment let $x$ = atomic weight of potassium; then we have—

$$108 : x + 35{\cdot}5 :: 10{\cdot}50055 : 7{\cdot}25682$$

and—

$$783{\cdot}73656 = 10{\cdot}50055\, x + 372{\cdot}769525$$

whence—

$$x = \frac{410{\cdot}967035}{10{\cdot}50055} = 39{\cdot}13.$$

—WM. JOHN GREY, F.C.S., Gateshead-on-Tyne.

[56000.]—**Chemical Problems.**—1. It must be taken for granted that the at. w. of silver is known to be 108. The formula, AgCl denotes that 108 parts by weight of silver are combined with $x$ parts by weight of chlorine.

Weight of AgCl 121·4993gms.
" Ag 91·4620 "
" Cl 30·0373 "

The question now is: If 91·4620 parts by weight of Ag combine with 30·0373 parts of Cl, how many parts will 108 parts of Ag combine with?

$$\frac{30{\cdot}0373 \times 108}{91{\cdot}4620} = 35{\cdot}4645$$

Therefore, 35·4645 is the at. wt. of chlorine. 2. In this case the reaction which takes place is represented by the following equation—

$$AgNO_3 + KCl = AgCl + KNO_3$$

by which we see that the Cl of the KCl combines with the Ag of the $AgNO_3$, and the fact that a surplus of silver is left shows that all the Cl has been displaced. Find how much Ag was used.

Silver taken 10·51995gms.
" left.. ·01945 "
10·50055

Taking the at. wt. of Ag = 108 and Cl = 35·4645, find the actual weight of Cl used. If 108gms. of Ag combine with 35·4645gms. of Cl, 10·50055gms. of Ag will combine with

$$\frac{35{\cdot}4645 \times 10{\cdot}50055}{108} = 3{\cdot}44811\text{gms. Cl.}$$

Again, Weight of KCl used 7·25682
" Cl " 3·44811
" K " 3·80871

If 3·44811gms. Cl combine with 3·80871gms. of K, 35·4645gms. of Cl will combine with

$$\frac{3{\cdot}80871 \times 35{\cdot}4645}{3{\cdot}44811} = 39{\cdot}1733$$

Therefore, 39·1733 is the at. wt. of potassium.—SALVO JURE.

[56002.]—**Planing Machine.**—You will find on p. 553 of the number in which your query occurs that I gave 25s. as the cost of planing the bed, and on p. 512 the cost of the bed, costing 36s., and its weight 3cwt. The standards are also given on p, 467 as weighing 125lb. each, and as costing 10s. or 12s. per cwt. The table also is given on p. 468 as weighing 180lb. The weight and probable cost of all the larger castings will also be given in due course. In assuming certain rates of cost, a margin must necessarily be allowed, owing to the difference in prices in different districts. Scarcely two firms charge alike, and the dearer are often the cheapest in the end. The best castings are wanted for a light machine, and I should not expect to get these under 10s. or 12s., while some of the smaller stuff will cost 14s. or 16s. One penny per superficial inch is a common charge for planing; but by making a contract bargain for the whole of the work, you might get it done at a considerable reduction.—J. H.

[56003.]—**Chimney Stacks.**—I have seen a great number of chimneys serving as uptakes for the exhaust steam, and having no visible cracks. In others not having the exhaust steam, my attention has been directed to serious cracks and flaws. I look for the substantial opinion of "ours" in regard to this question.—YAMA.

[56004.]—**To "Invicta."**—I think you hardly realise the simplicity of the question. I will, however, briefly explain it, and you will, I think, see the whole principle at a glance. Supposing you move the piston in your 12in. cylinder down for 6in., the air (supposing there was neither clearance nor passage way) would be compressed to 15lb.; supposing the piston is further lowered so that the air is compressed into a space of 4in., you would then have raised the pressure to 45, because you have compressed the air into a third of its normal volume; therefore, you may follow the rule I now give, which is as follows: Air compressed into half its bulk is equal to 15lb., to $\frac{1}{3}$rd three times or 45lb., to $\frac{1}{4}$th four times or 60lb., to $\frac{1}{6}$th six times or 90lb., and if to $\frac{1}{12}$th, or a compression of twelve times the pressure, would equal 180lb. Is this what you want to know?—Invicta.

[56005.]—**Oil-gas Generator.**—To "Invicta" or "R. A."—I have not the back numbers by me, but I feel pretty sure I have seen this discussed before; I would suggest, however, a single-acting cylinder, with a compressing pump, driven by a crank or other device. In my humble opinion, the Clerk engine is superior to the Tangye, owing to the fact that the compression and explosion are not in the same cylinder with the piston only between; not only so, but if this was not an advantage, surely the new Crossley twin engine would have a gland, and thus obviate the screw cylinder. I should certainly use the Fletcher's generator, and with a vertical engine see no reason why the plan should not succeed. I will try and obtain some further information on the subject and let you know.—Invicta.

[56006.]—**To Mr. Bottone and Others.**—I do not know King, Mendham's pattern No. 3, so I cannot advise exactly. I should say approximately 7lb. No. 16 on the fields, and ½lb. No. 20 on the armature. Three quart bichromates would work it: six ditto would do better still.—S. Bottone.

[56007.]—**Dynamo.**—To Mr. Bottone.—Your calculations are quite correct. If I might suggest, however, I would advise for such a large machine that the ring be kept a little lighter, and the space between the cogs a little shallower, say 1in. instead of 1½in. This allows the wire and the core to come nearer the pole pieces of the F.M.—S. Bottone.

[56014.]—**Internal Gear Wheels.**—Give me proper data, and I will strike out your teeth correctly for you. "Pitch of wheel 5in., pinion about 4in." is impossible. Please state pitch and number of teeth in wheel and pinion respectively, or pitch and diameter, which you like.—J. H.

[56016.] — **Chemical Pipelights.** — I have seen potassium sold in the streets for this purpose. A small piece is screwed up in a strip of paper, and when this is moistened with water the paper takes fire. I have also seen phosphide of calcium used. This is kept in tinfoil. A small piece when wetted with water decomposes and produces a flame, the reaction being shown by the equation—

$$Ca_2P_2 + 2H_2O = 2CaO + 2PH_2.$$

—Geo. A. Walton.

[56016.]—**Chemical Pipelights.**—I guess this must have been done with a little piece of sodium or potassium at the end of the paper, which would ignite on being dipped into water, and so light the paper. They would have to be made shortly before use, however, and the paper would have to be arranged so as not to get wet before the metal was alight.—R. A. R. Bennett.

[56017.]—**Ferrier and Soulier's Plates.**—To S. Bottone.—These are simply albumenised plates. Make an iodised albumen by whisking the whites of two or three new-laid eggs with a mixture of 15 grains potassium iodide and 5 grains of potassium bromide to each egg. Allow the froth to subside in a dry place free from dust. Pour off the clear solution. Coat plates, as with collodion; set on levelled slab to dry. When dry, expose to a heat of about 120° Fahr. to coagulate the albumen. Go into a dark room; sensitise in a bath of nitrate of silver solution 60 grs. to the ounce. Can be used wet or dry. If the latter, must be washed in several changes of water before drying. Expose 50 times as long as collodion. Develop with gallic or pyrogallic acid, well restrained with acetic acid. —S. Bottone.

[56020.]—**Leather Hams.**—The leather is sewn on the outside. You cannot bleach the leather. You may whiten it as much as you like by using a little of "Probert's breeches paste," which can be had of a saddler; or you may dissolve a little soap, and scrape some pipeclay in it till it is of creamy thickness; apply it with a bit of flannel or old toothbrush.—Verax.

[56021.]—**Home-Made Tents.**—I have had some experience with these, and would advise no application to be used to render the cloth waterproof. Use the material known as Government Duck, sew with seaming twine, the seams being double. (If you do not know how to do this write again.) The top angle of tent should not be greater than 60°, and then it will be quite water-tight. Make ground-sheet of same material; saturate it with water, spread on a table or board, and rub in linseed oil and boiled oil, equal parts, with a nail-brush. Use as little oil as possible, but enough to cover every part. Hang up to dry in open air for three or four days, and repeat process three or four times. Wet the sheet before oiling each time. After this give one coat each side with boiled oil without water. Do not mix soap or beeswax with oil, as is often recommended. Although it accelerates the process it does not produce so good a result.—Geo. A. Walton.

[56022.]—**Engines.**—Your query is incomplete. You must give us the diameter and length of stroke of the several pistons. If they are all equal, nothing is gained by altering the valves to ¾ cut-off. —Yama.

[56023.]—**Pattern-Making.**—There is a set of articles just commenced (Feb. 20) on the making of a set of patterns for a 3¼in. cylinder engine, which I should think would contain just what you require. There are also drawings of core-boxes on p. 449 in the number for July 20, 1883.—J. H.

[56025.]—**Trueing Grindstone.**—I really think it is too bad of your correspondent to make this request. The apparatus he mentions is a patented machine and the private property of a firm of manufacturers; yet, in spite of this, Mr. Williams requests some other correspondent to give him details of its construction, with the object presumably of making one for himself, and thereby infringing on the patent rights of the proprietors. If your correspondent did not know of its being a patent, it, of course, alters the case; but I think Ransome's catalogue calls it "Trier's patent." Or, perhaps he is not aware that he would still be infringing the patent if he only made one for his own use; but this does not alter the case, as no one but the proprietor of the patent or his authorised manufacturer has the right to make one for any purpose whatever. I have noticed similar tendencies on the part of others of your correspondents, and think they ought to be reprobated. I may say that we have the machine in use at our works, and find it a very useful one; but we should as soon have thought of making one for our own use as we should of any one making any of our patent machines for theirs. The machine may be bought for a small sum from any tool dealer, it being well known in the market. —Marcus.

[56026.]—**Engine.**—To "Invicta."—I will endeavour to get the necessary information for you in a few days. It is not my property—simply was asked to experiment with it, and get it as perfect as possible for the firm who are about to put it in the market. It is practically entirely of cast iron, and the experimental engine certainly runs most satisfactorily. One of these motors is now driving the electric light at a private house with the utmost satisfaction to the owners. It seems to me just the thing for amateurs.—Invicta.

[56027.]—**Lubricant for Small Machinery.** —Why does not "Microcycle" state what the machinery is, and then one could advise him what lubricant to use with advantage? If for clock or watch proceed as follows:—Cool olive oil till the stearine settles; decant the oleine and place in it some pieces of old lead. The lead oxide removes the free oleic acid and leaves nearly pure oleine. Rangoon oil, to be had of gunsmiths, is good for some small machines. Castor oil is also used for small machines where the motion is light and slow. —Geo. A. Walton.

[56027.]—**Lubricant for Small Machinery.** —I have used Stauffer's lubricant for some time in conjunction with his lubricators, and found it answer well.—Volt.

[56030.]—**Lead Burning.**—"Beginner" had better send some stamps to the publisher, and he will forward the back numbers containing most concise directions. To answer the question fully would take up too much room, and would only be a repetition of same.—Volt.

## UNANSWERED QUERIES.

*The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered are repeated four weeks afterwards. We trust our readers will look over the list and send what information they can for the benefit of their fellow contributors.*

## QUERIES.

[56031.]—**Reservoirs.**—What thickness of boiler-plate would be required in reservoirs, 6ft. in diameter, and 12ft. long, to withstand an outside pressure of from 10lb. to 14lb. per square inch, constant?—J. G., Bristol.

[56032.]—**Enamelling Steam-Gauge Dials.**—Could any reader kindly give me any information how to enamel steam-gauge dials, and what to use, and the kind of ink or paint to mark the figures with?—P. W.

[56033.]—**Shocking Coil.**—I have made a shocking coil with electro-magnet (contact breaker) with two layers of No. 18 c.c., and 16 layers of No. 36 silk covered. It gives too strong a shock. Kindly inform me how to remedy the same, so as to enable it to increase gradually. It is insulated with thin paraffined paper, and I use one pint cell, Bunsen, to excite it with. How can I regulate it—if possible, kindly state how?—S. D.

[56034.]—**Boiler for Engine**—I have a cylinder, 1in. bore, by 2in. stroke, and wish to make a boiler for it What size and thickness must it be, made of sheet iron, to stand about 50lb. pressure, and to supply plenty of steam? Should also be glad of any hints as to bending plates and flanges; boiler of ordinary vertical type;—how many tubes will it require? I thought about 18in. by 9in., with crown of boiler flanged inwards, so as to form smoke-box.—Yrrep.

[56035.]—**Books on Veterinary Medicine.**—Can anyone give me information as to the most recent and best works on equine medicine and pathology?—A. H. S.

[56036.]—**Steam Boiler.**—A boiler 20ft. long, 6ft. diameter, two tubes 2ft. 3in., firegrate in proportion What quantity of water should it evaporate at atmospheric pressure, that is to say, discharging into the open air without any pressure?—J. G., Bristol.

[56037.]—**Induction Coil.**—Would some electrical reader kindly explain the folllowing?—I have made an induction coil on a wooden bobbin, 8in. long, by 1in. core, diameter of ends, 4in. I have used two layers No. 16 c.c. for primary, and 3lb. No. 26 c.c. for secondary. The core is of thin iron wire. I do not know the gauge, but it is that used for fastening on the corks in lemonade bottles. On connecting to two Bunsen cells; carbons, 5in. by 1in. by ⅜in.; outer cells, 5in. by 4in. diameter, I get but comparatively faint shocks. I should like this explained, also how to make and connect condenser?—W. G. Glasgow.

[56038.]—**Restringing Grand Piano.**—Will any of your musical readers be kind enough to instruct me how to put strings on a Broadwood piano grand? There are no holes in the pegs. Every time I have tried, the wire unlaps off peg.—Old Musician.

[56039.]—**Explanation Wanted.**—On working the calculations out of governor, 44079, published July 15th, 1881, page 457, on line sixth under diagram, 8·6in. + 2in. = 10·6in., but I fail to see how it equals 0·9in. Also an explanation of the remaining part of the working, viz.:—

$$\frac{r^2}{\cdot 9} v^2 = 75, v = 8\cdot 7$$

—A Constant Reader.

[56040.]—**Knocking in Gas-Engine.**—Can any reader of the "E.M." tell me the cause of a half h.p. Otto gas-engine making a knocking noise in the crank every time there is an explosion? I might say it is a new engine—not had three months' wear?—kindly oblige.—One in a fix.

[56041.]—**Gun-Metal.**—Would feel obliged if any of your numerous correspondents would give me the percentages of the different metals necessary to produce gun-metal, that will resist the effect of a 3 per cent. solution of sulphuric acid?—D. Clifton.

[56042.]—**Voltmeter.**—To Mr. Paul Ward.—Some time ago you kindly gave me directions for above. I asked you to give a sketch of same, but I did not get any answer to my query. I suppose it missed you. Can you oblige now?—Volt.

[56043.]—**Engraving with Acid.**—I wish to engrave some figures and lines on bright steel with acid, and shall be obliged if some correspondent who has had experience in such work will kindly answer the following questions:—1. What kind of coating should be applied, and how should it be applied? 2. What kind of style is best for writing? 3. Should the article, when prepared, be plunged in the acid, or will it suffice to lay the acid on the parts to be acted upon? 4. What acids, or dilutions of acids, answer best?—Acier.

[56044.]—**Baths.**—Would some experienced plumber inform me what is the greatest practical horizontal distance that baths could be supplied with hot water from boiler attached to a large cooking range? Kindly state greatest horizontal distance, the baths being on first and second floors, one over another.—Stop-Cock.

[56045.]—**Lantern Lamps.**—Does a four-wick refulgent lamp, such as is advertised in this paper, give an appreciable increase of light over a three-wick one, when using 4in. condensers, and a slide of 2¼in. diameter? I believe there was a query touching four-wick lamps in these columns some time ago; but I have searched many back numbers to no purpose.—Exhibitor.

[56046.]—**Turning Spindle.**—After having turned a spindle as far up as I can get, still leaving a little to come off the end where the driver was on, I have changed centres. How is it that the spindle does not run true now?—Apprentice.

[56047.]—**G. B. Paper Enlargements.**—While thanking those who so kindly answered my former query, may I ask them to help me in this? What I want especially to know is:—1. Can really good enlargements be done with a ¼-plate apparatus, such as Lancaster's Le Merveilleux, by using a paraffin lamp? 2. Should the lamps be placed as close to the negative as possible? 3. Should the hole be cut out the same size as opening of shutter of dark slide? 4. Should the stop be removed from the lens while focussing? I perceive that a very small part of the picture in the centre was bright, and the rest shady.

5. How long should the developing be continued, supposing the image appears in about 20sec.? I make my developer from saturated solution of new oxa. potash, and pro. sul. iron. My picture when finished was far from being clear and white. Will over-exposure cause the paper to go black? I should also much like to know what harm is done to a negative if kept in the developer too long.—J. W.

[56048.]—**Burning Bricks on Wet Ground.**—I have just built three Newcastle kilns on filled-in meadow land, but I have a difficulty; I find that steam is constantly being drawn up whilst the bricks are burning, and on opening I always find about one third in the centre, crushed or steamed to dust. Is it possible for water to be drawn up from the meadow to do this mischief, and would, say 6in. of concrete in the bottom or floor, stop the water from spoiling the bricks, and if so, would any other effect be produced?—BRICKMAKER.

[56049.]—**Ventilation of Laundry.**—Can anyone of your readers give me any reliable information respecting the ventilation of the drying rooms of a laundry. I am in the greatest difficulty with one at present? Should the provisions be made at top or bottom, sides or centre, of the room, to carry off the foul and damp air?—LAUNDRY MAN.

[56050.]—**Platinotype Paper.**—In a number of the ENGLISH MECHANIC, Mr. W. J. Lancaster gives some brief particulars of platinotype printing; would he or some other reader kindly state proportions of chemicals for sensitising paper, and whether such must be previously salted, the same as for silver prints? Also whether the cost of process is less or more than silver prints?—C. W. S.

[56051.]—**Gramme Dynamo Machine.**—I have castings all framed up, for a 600-light machine. Will some electrician kindly inform me the size of wire for the ring, and also for the field-magnets? I want to have it shunt wound for incandescent lamps, also to charge accumulators; what might be the E.M.F. and ampères?—NEW SUBSCRIBER.

[56052.]—**Kerosene Lantern.**—Supposing a lantern in which kerosene is burned, should be thrown down—would there be any danger of the oil taking fire, and if so, what should be done to put it out? It would be useful to know the best method of putting out any of this class of oils, should they take fire, or set fire to other things; water is not suitable, I believe.—BRICKWALL.

[56053.]—**Singing Noises in the Head.**—In No. 1008, page 448 (reply 55842) Mr. T. R. Allinson, L.R.C.P., gives an extract of lecture from a gentleman on this subject, in which he says:—"lost noise in head, from which mother suffered many years, and I four or five." From the remarks with this from T. R. Allinson, it would appear he had given some advice to the gentleman. Would Mr. Allinson kindly repeat that advice to one who has not merely suffered four or five years, but 35 years, from this distressing complaint, as he says he has "got much and valuable information on the diet cure."—ARVONIA.

[56054.]—**Hardening Lock Springs.**—Could any reader tell me the way to harden lock springs?—and oblige.—ANXIOUS.

[56055.]—**Diazo Salicylic Acid Sulphate.**—Can any reader of this journal kindly inform me where I can obtain diazo salicylic acid sulphate? I have tried various places in London, and have been supplied at various times with salicylic acid—salicylous acid—salicylic acid dialised for it, but fail to get diazo salicylic acid sulphate, which I want. Is it a complicated process to make it?—C. W. S.

[56056.]—**Photographic Lenses.**—Would Mr. W. J. Lancaster, or some other reader, kindly say what would be the result of shifting the lenses of a 45deg. rapid symmetrical or 90deg. wide angle rectilinear, nearer to, or farther from the diaphragms, and also, in theory, what would be the result of thickening the glasses, keeping the outsides to the same radius? What is the radius required in a glass for a 45deg., and also a 90deg. single lens?—C. W. S.

[56057.]—**Ornamental Bricks, &c.**—Will any kind reader of "Ours" tell me how the cornice bricks, square panels, &c., so much used now, are made? I have made some with wood patterns and screw press; but patterns are so expensive to have made. Is there any special machinery for them, or are they made from plaster casts? How can I tell terracotta from clay; is there any particular difference—if so, what is it?—BRICKMAKER.

[56058.]—**Tires.**—Will any of your readers kindly inform me, through your columns, the average mileage that a 2½ Bessemer steel tire will run before becoming worn out?—NOGOW.

[56059.]—**Geneva Watch.**—I have a watch which, when kept still goes all right and keeps good time, but if carried in the pocket it frequently stops when taken out to be looked at. This is especially the case when nearly run down. It seems as if the impulse from the escape wheel is hardly enough to carry the wheel to the end of its beat, and let another tooth pass. Does this indicate too weak a mainspring—or what? The watch is thoroughly clean.—LL. B. A.

[56060.]—**Nickel.**—Suppose you have power and suitable lathes running at about 2,000 per minute, how would you surface or prepare and polish, when nickel plated, the following class of goods? Iron castings, say stove fronts, and wrought iron and steel, brass, soft metal such as pewter, &c. Kindly state best kind of glazers, wheels, bobs, &c., and polishing material to use?—F.

[56061.]—**Specific Gravity.**—In the determination of a vapour density by Gay Lussac's method, the following data were obtained: Weight of substance, 0·1163grm.; observed volume of vapour, 50·77 cubic c.m.; temperature of bath, 215 deg. C.; height of barometer, 755·5mm.; difference of height of mercury inside and outside of tube, 80·0mm.; height of spermacete or oil. Column reduced to millimètres of mercury, 16·9mm.; Required the specific gravity of the vapour, the density of hydrogen being taken as unity; also the weight of one litre at 0deg. C., and 760mm. bar. pressure?—Z.

[56062.]—**Chemical.**—Required the percentage composition, observed and calculated, vapour density, and formula of a body which gave the following analytical results: (a) 0·4245grm. yielded 0·5670grm. of carbonic acid and 0·3025grm. of water. (b) 0·1810 yielded 0·3855grm. of silver chloride and 0·0165grm. of metallic silver. (c) Determination of vapour density according to Gay-Lussac's method: Weight of substance employed, 0·0808grm.; temperature of the air, 8deg. C.; height of barometer, 789mm.; temperature of vapour, 50 deg. C.; volume 46·2 cubic centimètres. Difference of level, 140·5mm.; coefficient expansion of mercury, 0·0001815; coefficient of cubical expansion of glass, 0·0000262.—Z.

[56063.]—**Brazing Bicycle Forks.**—Will one of your readers kindly inform me how to braze together the forks of a bicycle?—AMATEUR.

[56064.]—**Troublesome Battery.**—1. Would some reader of the "E. M." give me some information that may lead me to discover what is the matter with my battery? Any suggestion would be gladly received. It is a six-cell Leclanché doing principally bell work, and its fault is the zinc poles get covered with some white matter and fibres growing from it, which, in time gets so thick the bells will not ring at all; then I scrape all the white matter off and return the poles at once again into the cells, and the battery is as strong as ever, but in a week they are as bad ever. I have tried amalgamation. Also, is it of any use recharging new porous pots with the carbon plate, and charge from the old pots of a Leclanché battery?—J. PARSONS.

[56065.]—**Tricycle Spokes.**—I recently bought a Cheylesmore, secondhand, in very fine condition except that the nickel-plating has peeled off the spokes and hubs in many places, and these parts are consideraby rusted. What is best to do with it? I have thought of painting the spokes and hubs with some suitable paint or enamel. Is there not a Harrington's enamel, and is it suitable? What colour is it, and how applied? Any advice will be gratefully received. I am far away in the north of Scotland, so must do the job myself.—C. W. B.

[56066.]—**Gas Purifier.**—Can any reader of "ours" suggest a plan by which gas can be purified and its illuminating powers increased, at the same consumption, or at less, if possible, than at present? Something after the principle of the Albo Carbon burner, in shape of a cylinder or box, to be fixed on service pipe just above meter.—J. B. C.

[56067.]—**Embossing on Brass.**—Will some reader inform me upon what substance embossing in brass is done, and also what thickness of sheet brass is most used? I have tried pitch, but it seems too brittle.—C. W. BACH.

[56068.]—**Adjusting Telescope in Dumpy Level.**—Would any experienced surveyor or mathematical instrument maker explain how telescope is adjusted for collimation in a dumpy level, and can it be done after bubble tube has been adjusted?—D. S.

[56069.]—**Photo. Amateur.**—Will some authority on this matter inform me what sizes the diaphragms require to be for a Ross's portrait lens, working at 7in. focus, so that each size smaller will require double the exposure of the previous one? I have a table (in Burton's book), but do not understand the decimals. Also whether four are sufficient?—P. A.

[56070.]—**G. E. Engines.**—Will "B." kindly give the numbers, date, and makers of the tanks he describes in letter 23872, and state whether the leading and trailing wheels have radial axle boxes or not? It seems probable they have.—W. B. P.

[56071.]—**L. and N. W. Engines.**—Wanted boiler and firebox dimensions and heating surface, also distribution of weight, of Ramsbottom's 6ft. coupled engines? W. B. P.

[56072.]—**Road Locomotive.**—Would it be practicable to run the ordinary road locomotive engine on rails, provided the wheels were properly grooved in the centre or flanged to fit on the rails, the width between the wheels being the same as the rail gauge? The thought is suggested by the proposed Suakim and Berber railroad. It would save expense, delay, and trouble if the wheels of portable engines were made very concave to run on soft soil and with a groove to enable them to run on rails where the soil might be too soft to carry the weight without them. The wheels of the rolling stock must be made to match.—LLOVER.

[56073.]—**Clock Query.**—To "FIZ FIG," or "WATCHMAKER'S APPRENTICE."—Having an old clock case I made a new movement, to go a month, to fit it, with dead beat escapement and 7lb. pendulum ball, but find it wants a tremendous weight to drive it, for pattern I had a German in the house which went remarkably well with a 10lb. weight. Every depth is correct and everything free. Would it go with less weight if I put a recoil escapement, and would you give me the rule to find weight (not in Algebra), as the only plan I know is to hang on extra weight till it goes? If any of "ours" could help me they will greatly oblige a—YOUNG AMATEUR.

[56074.]—**Photography.**—Gelatino bromide paper can be prepared in such a way as to colour rapidly on exposure to light, thus forming an indicator of the photo-intensity of the light on any particular day. Please give the best method.—VOLVOX.

[56075.]—**Hot-Air Engine.**—I have a strong horizontal slide-valve steam-engine, but no boiler. I want to make a hot-air engine of it: will you please say if air pump should be double acting? I am going to make pump piston with two rings on, same as engine piston—will that be right? What bore and stroke should air pump be?—engine cylinder is 4in. bore 8in. stroke. What size and strength of metal should air receiver be to bear the proper pressure and be safe? It will be cast iron, and be kept hot in a small furnace built of firebricks. A simple sketch of air pump and air receiver will oblige—MECHANIC.

[56076.]—**Rope Pulleys.**—Would any of the readers inform me if it is possible to get a motion with rope pulleys at right angles to each other, and how to place them?—GRANITE CITY.

[56077.]—**Specific Heat.**—From what height must a block of ice at 0deg. C. fall that the heat generated by its collision with the earth shall be just competent to melt it? From what height must it fall that the heat generated may be sufficient to convert it into steam?—Z.

[56078.]—**Green's Economiser.**—Can any reader tell me how to put a new pipe and bottom into a Green's Economiser?—ONE IN A FIX.

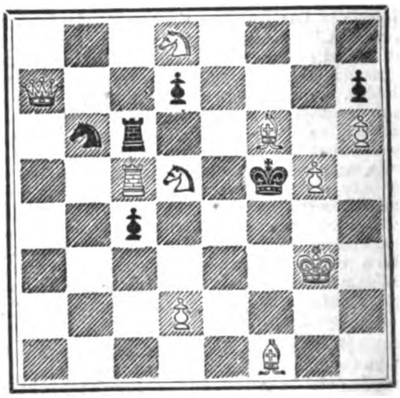
## CHESS.

ALL Communications for this department must be addressed to J. PIERCE, Llandwrog, Carnarvon.

### PROBLEM DCCCCXXIX.—By DR. GOLD.

(From his collection).

*Black.*



*White.* [10+6

White to play and mate in two moves.

SOLUTION TO 927.

| *White.* | *Black.* |
|---|---|
| 1. B-Q 8 | 1. P-KKt 4 (best) |
| 2. Q-KKt 4 | 2. Kt takes Q |
| 3. R-KR 8 mate | |

With a view to obtaining, if possible, a sufficient number of problems for the tourney, we propose extending the time of entry to March 31. If more are not sent in, it will have to be abandoned. The solution tourney will therefore begin with first number after that date.

### NOTICES TO CORRESPONDENTS.

CORRECT solutions to 927 by E. Rosling, J. Hughes, Raymond, C. Meiklejohn, E. S., E. Stanley Follwell (very poor), Rev. W. Anderson (old Romney), J. E. Piper; to 926 by S. L. Chivers.

R. HOLSTER.—We have pleasure in entering your name. No payment is necessary. Get Cook's Synopsis of the Openings, and take every opportunity of playing with better players than yourself.

C. MEIKLEJOHN.—The solution was duly received and was correct. We are sorry for omission in not acknowledging receipt. The competition is for solving problems. There is also a Problem Tourney.

J. Hughes.—What you point out is to be regretted, but it is beyond our control.

TOURNEY Problems received from Respice Finem, and Tessie.

CHESS STRUCK.—Sealed envelope, but no problems.

ENGLISH MECHANIC Chess Tourney game between Mr. W. Nash (White), and Mr. G. H. Mainwaring (Black).

1. P-K 4, P-K 4 / 2. P-KB 4, P takes P / 3. B-B 4. Q-R 5 (ch) / 4. K-B sq. P-KKt 4 / 5. Kt-QB 3, B-Kt 2 / 6. P-Q 4, Kt-K 2 / 7. Kt-B 3, Q-R 4 / 8. P-K R 4, P-K R 3 / 9. K-Kt sq, P-Kt 5 10. Kt-K sq, P-Q B 4 / 11. Kt-Kt 5, B takes P (ch) / 12. Kt takes B, P takes Kt / 13. Q takes P, P-B 3 (a) / 14. B takes P, Q Kt-B 3 / 15 Q-Q 6 (b), Kt-Kt 3 (c) / 16. Kt-Q 3, R-B sq (d) / 17. R-Q sq, P-Kt 6 / 18 Kt-Q B 5, Kt (B 3)-K 4 / 19. B takes Kt, Q takes R (e) / 20. Kt takes Kt P, Q takes Kt P (f) / 21. Q takes Kt P, Q takes Kt / 22. Q takes Kt (ch), K-Q sq / 23. Q takes B P, Q-Kt 3 (ch) / 24. K-R 2, R-K sq / 25. Q-B 4, B-Kt 2 / 26. R-Q 6, Q-B 4 / 27 B-Q 5, R-Q Kt sq / 28. R-Q sq, K-B sq / 29. R-Q 4, B-R 3 (g) / 30. Q takes P, R-Kt 3 / 31. R takes R, P takes R (h) / 32. R-Q R 4, R-B sq / 33. Q-Q 4, Q K 2 / 34. P-K Kt 3, B-Kt 2 / 35. B takes B (ch), K-Q sq / 36. Q takes Kt P (ch), K-K sq / 37. B-Q 5, Resigns.

NOTES BY MR. NASH.

(a) I do not think this was the best move. I prefer R-Kt sq.

(b) This move gives White a decided advantage.

(c) P-Kt 3, threatening to exchange Queens and giving the Black Bishop an opening, would, I think, have been better.

(d) This seems necessary now to protect the Bishop's pawn.

(e) 19. Kt takes R would have given him a better chance of a draw. There would then have followed 20. Kt-K 6, P takes Kt / 21. B takes P, Q takes R (ch) (best) / 22. Q takes Q, B takes B / and although I could have won two more pawns, I should have had some trouble to win the game.

(f) As good perhaps as anything, for if 20. . . Q takes KP / 21. Q takes QP (ch), B takes Q / 22. Kt-Q 6 (ch), &c.

(g) If 29. . . . B takes B / then 30. P takes B.

(h) If 31. . . . Q takes R 32, Q takes Q, P takes Q / 33. P Kt 4.

A CHINESE torpedo boat has been recently launched at Ningpo. Its speed is said to be 19 knots per hour.

# ANSWERS TO CORRESPONDENTS.

*⁂ All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, 332, *Strand, W.C.*

## HINTS TO CORRESPONDENTS.

**1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.**

**⁂ Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.**

## BACK NUMBERS.

WE receive so many queries asking for directions how to make many instruments and appliances which have been fully described in back volumes that we have compiled a list, which we shall insert in this column at intervals, of those most frequently sent, and as the numbers are still in stock, new subscribers should consult the list before sending their questions.

Batteries: Nos. 715, 718, 734, 741.
Bellows camera: No. 897.
Bookbinding: Nos. 613, 770.
Coils, induction: Nos. 832, 885
Coils, medical: Nos. 844, 898.
Copying processes: Nos. 750, 753, 761, 762.
Electric machines: Nos. 628, 759, 840.
Electro-magnets: Nos. 756, 772, 783, 864, 872.
Electro-plating: No. 833.
Lacquers: Nos. 622, 866.
Magneto-electric machine: Nos. 783, 826.
Pattern Making: Nos, 938, 941, 943, 945, 948, 950, 952, 954, 955, 956, 958, 959, 962, 963, 965, 969, 973, 974, 978, 981, 986, 989, 993, 995, 998, 1,000, 1,001, 1,0(3 1,004, 1,008, 1,009, 1.010.
Silver-plating: Nos. 830, 868, 870, 874.
Telephones: Nos. 695, 747, 828, 853, 865.
Varnishes: 478, 619, 675, 691, 723, 775.

## A NEW VOLUME.

THIS number is the first of Vol. XLI. Readers willing to oblige us by recommending "Ours" to new subscribers should do so now, when a new volume is commencing. The index to Vol. XL. will be published *on March 20*, and cases and bound volumes will *be on sale* shortly after. Readers desirous of making up their sets for binding the past volume are recommended to do so at once, as the back numbers soon run out of print.

**The following are the initials, &c., of letters to hand up to Wednesday evening, March 4, and unacknowledged elsewhere:—**

COL. SIR FRANCIS FESTING.—E. P. Alexander.—C. Tayler.—A. F. Stevenson.—T. Taylor.—Rev. J. Lamont.—F. H. Holmes.—Rev. J. B. Annesley.—W. F. Fisher.—G. D. Neill.—H. King.—Sir Rowland Stephenson.—C. S. Stock.—Resultant Force.—G. Jackson.—T. Plunkett.—J. C. Baker.—Pump.—Dens.—Four of Us.—G. H. B.—Calix.—G. Rowlands.—Amateur.—Sulphur.—C. W.—H. J. S.—Belgian.—F. M. C.—Annie.—Athos.—W. H. Elphick.—Ham.—A Fellow of the Royal Astronomical Society.—Thompson.—E. M. Nelson.—Baffled.—Arvonia.—Englethwaite.

AN OLD SUBSCRIBER. (You should consult a medical man; but you will find treatment for diabetes in Vol. XXXV. pp. 310, 478, 529; Vol. XXXII. pp. 17, 71, 117; and especially as concerns diet in Vol. XXXI. pp. 504, 528, 552, 599. A diet of absolutely nothing but skim milk has been found very useful, but in so serious a malady skilled advice should be sought.)—GREY HAIR. (Take litharge 1 part, starch 2, fresh-slaked lime 2, all in fine powder, and thoroughly dry; mix, and keep in a stoppered bottle. If the hair was black, mix this powder with water; if brown, with milk. Rub it into a thin paste, and smear it on the hair, which must be previously well cleansed with soap and water and dried. Work the paste well round the roots and on every part of the hair, and cover it with several thicknesses of paper thoroughly damped or an oilskin cap. In about three or four hours the powder may be rubbed off.)—C. H. (The solar day is longer than the sidereal because the sun appears to move about 1° per day from W. to E.; a solar day is the interval that elapses between two transits of a given meridian by the sun; a sidereal day is the time of one complete revolution of the firmament or the time between two transits of a fixed star. Mean time is that indicated by a carefully-regulated clock; a sundial gives apparent time. As to the "universal day," see recent back numbers. That is not likely to be adopted, but the mere mention has led to much confusion of thought, as you have discovered in the blunders of the *Times* correspondent.)—PORTABLE. (Use some of the anti-incrustators which you will find advertised.)—BLACKSMITH. (Dr. Percy's "Metallurgy of Iron and Steel," John Murray, is a standard work; but you will find an account of Bessemer steel-making in many works and cyclopædias.)—INDIARUBBER. (We believe it is cut up and masticated in the machine and subjected to the action of steam, when much of the sulphur and other materials separate; but you cannot get "pure" rubber from it.)—SHUNT. (The title of "professor" is legitimately held only when applied to someone who occupies a "chair" at some university or other recognised institute for teaching; but there is nothing to prevent a man dubbing himself "professor"—of hair-cutting, of legerdemain, or anything else. 2. We do not recognise it by name. 3. Because with the shunt machine there is no likelihood of the accumulators overpowering and reversing the dynamo. The name is sufficient, but to save trouble put Charing-cross.)—C. S. V. BROWN. (For simple accumulators see p. 28, No. 1,016. Pocket batteries are generally used.)—UNCLE SAM. (Chisels and graving tools; bed either block of beech or slab of lead. 2. Galvanising implies the use of zinc. Frequently described. Pickle in acid liquor; rinse well, dry quickly, and immerse in a bath of zinc covered with layer of sal-ammoniac.)—J. BANCROFT. (We cannot republish old matter while the back numbers containing it can still be purchased. We should have to treble the size of our paper to answer fully all the questions that reach us every week, especially requests for recipes that are given in many text-books.)—W. J. G. (Short sight can be remedied by the use of spectacles when the subject is young. Open-air occupations are naturally conducive to a cure.)—C. C. (See No. 896, p. 253, and various replies in back volumes.)—E. F. (See previous answer.)—ACID. (Look through recent back numbers, or the forthcoming index. Recipes for lacquers have been frequently given, but as a rule it is much cheaper to buy them.)—X. (The one mistake has been explained, and we cannot afford space for your personal exculpation. If you will refer to p. 277, Vol. XXXIX., you will see that you have made a mistake; you misunderstand the legal meaning of the words "use" and "experiment." You may make a patented invention for the purpose of "experiment," but you must not "use" it in the ordinary sense of that term.)—E. R. T. (There is no work of the kind: that is why we devote so much space to questions in connection with the subject.)—NIKO. (We believe it is supplied only to yearly subscribers; but apply to Messrs. Trübner, Ludgate-hill, E.C.)—RUB. (We answered you before. You cannot make them without apparatus and the prepared materials, and you can obtain full instructions with them. The method has been described in back volumes.)—QUERIST. (See back numbers, or communicate with the secretary of the Cyclists' Touring Club.)—C. H. (Query inadmissible. See the advertisement columns and the index of Vol. XXXIX., under head Gas Engines.)—VENTO. (Did you boil the tar and pitch until all the moisture was out? If not, try again. Full directions in back numbers—No. 995, p. 155, for instance.)—ORDERIC VITAL. (Thanks. The paper is in preparation, as we intend to give at least the substance of it.)—C. J. E. (Yes, it will do. Permission must be obtained of the Commissioners of Works for taking photographs in the royal parks, but no order is necessary in the case of public buildings. As far as the latter are concerned, for reasons which can be readily understood, it would be as well to have satisfactory credentials in your pocket—might save a little inconvenience.)—W. T. (The Sanitary Institute, 74A, Margaret-street, W. Particulars can be had of the Secretary.)—TROUBLED ONE. (You want the white face only temporarily, we suppose. Any druggist will supply you with suitable preparations; or if you can get hold of a "dresser" at one of the theatres he would explain how to make up for any part.)—S. T. G. (Look up your back numbers, and don't talk about working a "dynimo" by a heavy weight with a 20ft. drop.)—GRAMEN. (The best way is by means of the clamps, specially designed for such purposes. 2. Could be done, but what would be the object? 3. If you mean telephones, see back numbers. 4. An inch and a half or two inches. 5. Full directions for making phonograph in Vol. XXVII. p. 157.)—W. PAGE. (Yes, quite possible. See the indices for multiplex or quadruplex telegraphy, the latter fully described and illustrated by a diagram in No. 542.)—INQUIRER. (Any bookseller will supply you with French newspapers and books.)—J. K. S. (It does not make any difference where the subscription is paid. 1. It means so much per ton. 2. One foot of inch square bar iron weighs 3·3lb. 3. The price of a cwt. lump would depend on where it was bought. 4. Ten per cent. more will do. 5. It is absurd to ask "what sized steel rope would be strong enough to support one cwt." A piece of piano wire will do that. 6. Pitman's.)—BEGINNER. (In some of the drawing books, or in such papers as the *Engineer*, which occasionally publishes working drawings. 2. We do not know whether any one publishes them; but join one of the Science and Art classes.)—J. HALES. (Perhaps the articles were not thoroughly clean; but as you do not say what solutions and battery power were employed, we can only refer you to back numbers. Coat the articles of lead with copper by immersing in strong solution of sulphate of copper and touching with an iron rod; then plate on the copper.)—CONFECTIONER. (The only way is to put in silvered glass. You cannot readily silver the glass already in the frames, though an expert might possibly succeed if you could induce him to undertake such a job. It would, however, cost more than replacing with silvered glass.)—GAMMADION. (No. 20 cotton-covered would do. 2. We know of no book of the kind. Read back numbers. 3. There is nothing to prevent you propelling a tricycle by electricity. It is the speed that is limited.)—E. L. (Why must it be coated? Silk is the best thing; but we think the ordinary leads as manufactured for tropical countries would do.)—ETRISCION. (See Hints No. 4, and consult the advertisements. The Daniell battery will be best for such work, and the magnets may have cores of 3-16in. iron 1½in. long, wound with No. 26.)—A. B. C. (The size varies with the pitch of reed. A good channel frame for a set of 8ft. reeds runs from 4⅜in. to ⅜in. for lengths by 1¼in. to 0in. for depths. The width depends on the keys.)—AMATEUR. (You must have a light in the roof and one in the side. See the indices; but the wisest plan is to take a lesson from existing studios.)—ONE WHO IS TRYING TO IMPROVE IN THE WORK. (The apparatus for making rubber stamps can be obtained from advertisers.)—SUFFERER. (If you would study the laws of health, take plenty of exercise in the open air, and not fancy you are ill; you would probably soon get better.)—SPINNER. (No room for spinning wheel; but you will find one in back volumes. 2. There is nothing very special in such a trap. Copy the familiar mouse or rat trap on a larger scale. 3. Use Indian ink and paint it on; but most people find it cheaper to buy such paper.)—TINMAN. (If the burner is properly constructed, and the flame regulated, there is neither smoke nor smell. Your arrangement would, of course give more heating surface, but in itself would not remedy the smoke nuisance.)—BOSCO. (Directions for making all kinds of batteries have been given over and over again. For such a purpose a Daniell would be best.)—AMATEUR. (Steel reeds are best, but there is no quick way of filing them. It is because a great deal of labour has to be expended on them that they cost so much. They are not voiced in the proper sense of the term. Look through the indices for reference to the subject. We do not understand what is meant by the scale used in tuning.)—L. DENIS. (We shall be glad of the proffered description of the dry-plate camera for outside work.)

**Dr. Carter Moffat's Ammoniaphone** (Harness' Patent). This excellent invention for strengthening and improving the voice, and for curing ASTHMA, BRONCHITIS, and all pulmonary affections, of which a full description, illustrated by a sectional view of the instrument, appeared in the ENGLISH MECHANIC for Dec. 26th, has been secured by the Medical Battery Co., 205, Regent-street, London, W. Its efficacy is vouched for by the highest medical, scientific, and social authorities, and Dr. Carter Moffat attends daily at 205, Regent-street, London, W., to demonstrate its extraordinary utility. Residents at a distance should write for "The History of the Ammoniaphone," sent post free to any address. Dr. Carter Moffat's Ammoniaphone will be sent post free to any address on receipt of P.O.O. or cheque value 21s., and payable to C. B. HARNESS. The Medical Battery Co., 205, Regent-street, London, W.—[ADVT.]

**Every Workman connected with the Building** Trades requiring a Situation should advertise in "THE BUILDING NEWS," published every FRIDAY, price Fourpence, at 332, Strand, London, W.C.
"THE BUILDING NEWS" is the Principal Journal representing Architects and Builders, and has the largest circulation of any Professional Journal in the kingdom.
Every Workman should insist on seeing "THE BUILDING NEWS" every week at his Club or Coffee House. He will find more "Lists of Tenders" for new work in it every week than in any similar paper, and can thus judge where work is likely to be had. He is also specially invited to make use of "Intercommunication" if he wants to know anything about his trade; to write to the Editor if he has any suggestions to make, and to advertise in the paper when he wants work.
The charge for Advertisements for Situations is On Shilling for Twenty-four Words, and Sixpence for every Eight Words after

## TERMS OF SUBSCRIPTION.

### PAYABLE IN ADVANCE.

**6s. 6d. for Six Months and 11s. for Twelve Months, Post-free to any part of the United Kingdom. For the United States, 13s., or 3 dols. 25c. gold; to France or Belgium, 13s., or 16f. 50c.; to India (via Brindisi), 15s. 2d.; to New Zealand, the Cape, the West Indies, Canada, Nova Scotia, Natal, or any of the Australian Colonies, 13s.**

**The remittance should be made by Post-office order. Back numbers cannot be sent out of the United Kingdom by the ordinary newspaper post, but must be remitted for at the rate of 4d. each to cover extra postage.**

**Messrs. JAMES W. QUEEN and Co., of 924, Chestnut-street, Philadelphia, are authorised to receive subscriptions for the United States for the ENGLISH MECHANIC, at the rate of 3 dols. 25c. gold, or Thirteen Shillings per annum, post-free. The copies will be forwarded direct by mail from the publishing office in London. All subscriptions will commence with the number first issued after the receipt of the subscription. If back numbers are required to complete volumes, they must be paid for at the rate of 4d. each copy, to cover extra postage.**

**Vols. IV., VII., XXVI., XXVIII., XXX., XXXII., XXXIII. XXXIV., XXXV., XXXVI., XXXVII., XXXVIII., XXXIX. bound in cloth, 7s. each. Post free, 7s. 9d.**

Vol. XL. ready shortly.

**All the other bound volumes are out of print. Subscribers would do well to order volumes as soon as possible after the conclusion of each half-yearly volume in February and August, as only a limited number are bound up, and these soon run out of print. Most of our back numbers can be had singly, price 2d. each, through any bookseller or newsagent, or 2½d. each, post-free from the office (except index numbers, which are 3d. each, or post-free 3½d.)**

**Indexes for Vols. I., VI., VII., VIII., and IX., 2d. each. Post free 2½d. each. Indexes to Vol. XI. and to subsequent vols., 3d. each, or post free, 3½d. Cases for binding, 1s. 6d. each.**

## CHARGES FOR ADVERTISING.

| | s. | d. |
|---|---|---|
| Thirty Words .. .. .. .. .. .. .. | 2 | 6 |
| Every additional eight words.. .. .. .. .. | 0 | 6 |

**Front Page Advertisements Five Shillings for the first 40 words, afterwards 6d. per line. Paragraph Advertisements One Shilling per line. No front page or paragraph advertisement inserted for less than Five Shillings. Reduced terms for series of more than 6 insertions may be ascertained on application to the Publisher.**

**ADVERTISEMENTS in EXCHANGE COLUMN—for**

| | s. | d. |
|---|---|---|
| Twenty-four words .. .. .. .. .. .. | 0 | 3 |
| For every succeeding Eight words .. .. .. | 0 | 3 |

**ADVERTISEMENTS in the SIXPENNY SALE COLUMN.**

| | s. | d. |
|---|---|---|
| Sixteen words .. .. .. .. .. .. .. | 0 | 6 |
| For every succeeding Eight Words .. .. .. | 0 | 6 |

**⁂ It must be borne in mind that no Displayed advertisements can appear in the "Sixpenny Sale Column." All advertisements must be prepaid; no reduction is made on repeated insertions; and in cases where the amount sent exceeds One Shilling, the publisher would be grateful if a P.O.O. could be sent, and not stamps. Stamps, however (preferably halfpenny stamps), may be sent where it is inconvenient to obtain P.O.O's.**

**The address is included as part of the advertisement, and charged for.**

**Advertisements must reach the office by 1 p.m. on Wednesday to insure insertion in the following Friday's number.**

## NOTICE TO SUBSCRIBERS.

**Subscribers receiving their copies direct from the office are requested to observe that the last number of the term for which their subscription is paid will be forwarded to them in a PINK Wrapper, as an intimation that a fresh remittance is necessary, if it is desired to continue the Subscription.**

**Epps's Cocoa.**—Grateful and Comforting:—"By a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by a careful application of the fine properties of well-selected Cocoa, Mr. Epps has provided our breakfast tables with a delicately flavoured beverage which may save us many heavy doctors' bills. It is by the judicious use of such articles of diet that a constitution may be gradually built up until strong enough to resist every tendency to disease. Hundreds of subtle maladies are floating around us ready to attack wherever there is a weak point. We may escape many a fatal shaft by keeping ourselves well fortified with pure blood and a properly nourished frame."—*Civil Service Gazette*.—Made simply with boiling water or milk. Sold only in packets, labelled—"JAMES EPPS and CO., Homœopathic Chemists London."—Also makers of Epps's Chocolate Essence

**Holloway's Pills.**—These Pills cleanse the vital fluid from all contaminations, and by that means strengthen and invigorate the whole system, healthily stimulate the sluggish organs, repress over-excited action, and establish order of circulation and secretion throughout every part of the body. The balsamic nature of Holloway's Pills exercises marvellous power in giving tone o debilitated and nervous constitutions.

☞ A CHANCE OF A LIFETIME!

Together with 193,747 useful and valuable articles, worth from One to Two Shillings each, making a total of 200,000 valuable and useful articles to be given to our Subscribers on MAY 15th, 1885, so that each and every one who subscribes before that date will receive THE HOUSEHOLD JOURNAL six months and a beautiful Present besides. The Prizes will be awarded MAY 15th, 1885, full particulars of which will be given hereafter, and published in the Journal. Subscribers can have Presents forwarded to any part of the United Kingdom. Printed lists of the awards will be forwarded to all Subscribers, and also published in the JOURNAL immediately after the award.

THE HOUSEHOLD JOURNAL Is one of the most BEAUTIFUL and POPULAR MAGAZINES OF THE DAY. It contains Twenty Large Pages, and has an elegantly engraved, illustrated, and tinted Cover. It is replete with beautiful illustrations and choice literature. No expense is spared to make this publication one of the finest in the world.

REMEMBER, WE MAKE NO CHARGE for these presents. The Two Shillings is the regular subscription price for six months to the JOURNAL, and some one is sure to get a Grand Prize of £1,000. OUR PROFIT will come from our advertising patronage, which will be very large, at remunerative rates. We want 200,000 new subscribers before May 15th, and as we are now receiving daily as many as 3,000, we are sure to get the required number. There will be no postponement. Persons wishing to subscribe for a year will receive two receipts for Four Shillings or 52 stamps, entitling them to a year's subscription and two presents.

REMEMBER, we send the JOURNAL direct to your address, post paid, and enclose a numbered receipt for each six months' subscription in the first number you receive.

A FREE SUBSCRIPTION TO YOU.—If you will get five friends to join you, and send us Ten Shillings all at one time, we will send six subscriptions for six months and six numbered receipts, good for six presents. Send Twenty Shillings at one time, with the names of ten friends or acquaintances, and we will send twelve subscriptions and twelve numbered receipts, and so on, thus giving you an extra receipt and subscription for every five subscribers you send in, and each subscriber gets a numbered receipt, and will get one of the presents mentioned above. The JOURNAL is sent, post paid, direct to each subscriber's address you send us.

SEND MONEY by Registered Letter or P.O. Stamps should not be sent when P.O. can be obtained. SPECIMEN COPY, 4d.

Address—THE HOUSEHOLD JOURNAL, H. C. Edwards, Manager, 31, Bouverie St.,
FLEET STREET, LONDON, E.C.

CUT THIS OUT AND SHOW IT TO YOUR FRIENDS, NEIGHBOURS, AND ACQUAINTANCES, AND PERSUADE THEM TO JOIN YOU, AND THUS GET YOUR OWN SUBSCRIPTION AND RECEIPT FREE. AGENTS WANTED

## OUR EXCHANGE COLUMN.

*The charge for Exchange Notices is 3d. for the first 24 words and 3d. for every succeeding 8 words.*

"**Blackie's Comprehensive Atlas and Geography**," almost new, perfect, in 10 parts, cost 60s. Want small lathe or cash offers.—F. Drake, Pavilion-place, Exeter.

Wanted, "**Spon's Dictionary of Engineering**," mechanical movements. Exchange.—A. C. Bell, Metallurgist, Main-road, Bexley Heath.

**Pedometer**, in silver cases, and perfect condition. Exchange up to 25s. Cash 15s.—M. E. B., 152, Grove-street, Liverpool.

Wanted, back-geared **Headstock**, or lathe parts, in exchange for double gun, books, and other articles.—R. Walker, junior, Balance-street, Uttoxeter.

Wanted, "**Rankin's Machinery and Millwork**," or others. Exchange.—P. H., 108, Brunswick-road, Sheffield.

**Engine and Boiler** wanted, ¼ to ½ H.-P., in exchange for electrical or photographic apparatus, or would hire.—E. H. Davies, Ebnal Lodge, Oswestry.

Wanted, "**The Electrician**," or "Electrical Review," in exchange for "Iron," "Colliery Guardian," or Mining Journal."—E. H. Davies, Ebnal Lodge, Oswestry.

Nos. 1 to 10 "**Knight's Mechanical Dictionary**," for Nos. of "E. M." containing Bottone's articles on Dynamo, or small magneto machine.—C. Provis, Emsworth.

Wanted, second-hand **Pump**, complete with eccentric, for 2 h.-p. boiler. Exchange.—Hy. Cox, junior, Wells, Somt.

I will give **Astronomical Books** in exchange for a good muzzle-loading gun of good make.—Apply, Sydney Pocklington, 9, Pelham-street, Newark.

I will exchange the "**Fishing Gazette**" for the English Mechanic weekly.—G. C. Davies, Orwell House, Town Close, Norwich.

**Folding Tailboard**, with side wing and winch screw, for ½-plate camera; plate box for ½ and ¼-plates, stereo camera, magnesium lamp, retouching desk, takes any size or shape up to ½-plate; cutting board, for cutting glass plates photo sizes. What offers?—W. R. Simpson, Lowestoft.

Lever **Watch**, silver face, gold figures and flowers. Wanted, Ross's Rapid Symmetrical for ½-plate.—W. R. Simpson, Lowestoft.

Musical Mechanical **Monkey Playing Harp**, plays two tunes, cost 5 guineas. What offers? Makes splendid attraction for shop window. Photo 4 stamps.—W. R. Simpson, Lowestoft.

Wood body **Enlarging Lantern**, 4½in. condenser, bellows front, no front lens, 2-wick paraffin lamp. What offers?—W. R. Simpson, Lowestoft.

Concert **Flute**, 8 keys, holes bushed, value £2; Piccolo 6s. Wanted, carpenter's tools, bicycle, or anything useful.—J. B. Lock, Martock.

Owing to death of late owner, I will Exchange old **Violoncello and Bow**, played in church 60 years ago, for a 52in. Bicycle, suit learner, or offers.—Alfred Gilders, Brightlingsea, Essex.

Weir's 55s. **Sewing Machine** and Albo-Carbon Gas Burners, for microscopical books and apparatus, or English Encyclopædia.—K., 30, High-street, Maldon.

"**English Mechanic**," 460 to 828, six missing; 962 to 1,033, unbound, slightly soiled. Offers, bicycle, or exchange.—111, Fort-street, South Shields.

Pair achromatic **Binoculars**, theatre, field, and marine powers, cost 4 guineas November last. Bill shown. 52in. bicycle wanted.—111, Fort-street, South Shields.

**Glazier's Diamond**, good.—Day, 56, Driffield-road, Old Ford, London.

**Speculum**, silver-on-glass, 9 diameter, focus 6ft. 2½in. good definition.—Day, 56, Driffield-road, Old Ford, London.

Bradbury and Co.'s Belgravia **Sewing Machine**, in good working. What offers?—M. Cockerell, Haslingden, near Manchester.

Small portable **Stove** for anything useful. Sir E. Beckett's latest "Clocks, Watches, and Bells" wanted, in good condition.—Lowest price to W. J., 78, Viaduct-street, E.

Exceedingly valuable **Specifications**, 6 vols., lately the property of an eminent C.E., including specification of Royal Exchange, 1842; London Docks, and over 100 on Locks, Bridges, Docks, &c., &c., all of works (chiefly public) actually carried out. Architectural Books in exchange to value of £4.—Full particulars from J., 759, Old Kent-road, S.E.

Volumes "**English Mechanic**," "Design and Work," "Carpenter and Builder," "Journal Horticulture," air gun, photo apparatus. Exchange anything mechanic, scientific, or useful.—Carey, Foynes, Limerick.

About 50 **Magic Lantern Slides**, photo. views, some Scotch. Will exchange for others.—Address, Finlay, 135, Renfrew-street, Glasgow.

Vertical half horse-power **Engine**, quite new, disc, crank shaft, brass bearings. Exchange for camera.—Jackson, Engineer, Bloxham.

**Castings and Forgings** complete of Engine and four sets of Fans. Exchange for magic lantern or camera.—Jackson, Engineer, Bloxham.

For exchange, a 54in. **Bicycle**, ball bearings to both wheels, steel frame, in good condition. Wanted a 50in. similar to the above, must be in good condition.—Address, Wm. Whiteley, 2, Rhodes-terrace, Bolton, Bradford, Yorks.

**Orguinette**, cost 55s., and 120 feet music. Exchange for watch, telescope, or anything useful.—F. Clarke, Cofton Cottages, Lodge-road, Birmingham.

Splendid ivory-handled **Knife**, best quality, contains three blades. Will exchange for novels or other books to value of 2s.—Gilbert, Oxford-road, Sheffield.

Wanted, **Lathe Wheel**, 24in. dia., 4 speeds, grooved 1¼in. bore. Exchange Heavy Flywheel, 30in. dia., 1¼ bore.—C. L. Gurden, Highcross, Leicester.

**Cornet**, by Distin, London, in good playing condition, two tones and Card Holder. Exchange Violin, Clarionet, or offers.—Teague, Roundwell-street, South Petherton, Ilminster.

Wanted, 48in. or 50in. **Bicycle**. Exchange 7½in. centre Lathe Head, 24in. bellows and frame. Lot cost £4 10s. Other exchange.—W. Smith, Bilston-road, Wolverhampton.

"**English Mechanic**," 38lb. weight, fair condition, Exchange for good Violin to suit a boy, or Violoncello.—F. G. F., 16, Carlton-street, Cheltenham.

A good back-steering **Tricycle**, ball bearings to all wheels. Exchange; new 18 months ago.—29, Mill-lane, Warrington.

"**English Mechanic**," Vols. XXX., XXXI., XXXII., XXXIII., complete, except two numbers. XXXIV., XXXV., XXXVI. incomplete. "Design and Work," Vols. IV., V., VI., VII., complete. VIII., IX., X., 8 numbers lost. Smyth's "Sidereal Chromatics." Exchange Coloured View Lantern Slides.—Z., 7, Myrtle-street, Hoxton, N.

Wanted, 52in. to 56in. **Bicycle**, in exchange for a Watch; capital timist; value £3 10s.—Payne, care of Mr. Marriott, Bridge-street, Peterborough.

Complete set of Dorrington's ½ H.-P. **Vertical Engine Castings**, cylinder bored and turned, and one cover turned. Exchange for anything useful.—F. Noakes, 11, Avon-street, Leicester.

54in. "Rapid" **Bicycle**, balls to both wheels, nickel-plated, adjustable step, brake, &c. Exchange for Amateur's Portable Lathe, Tools, &c.—J. H. B., 17, Eardley-road, Streatham.

"**English Mechanic**." Exchange Vol. XXXVII. and odd numbers Vols. XXII. to XXXIX. Wanted Vols. I. to VI., or odd numbers Vols. VII. to XV., XXXVI., or offers.—Walker, 55, Renfrew-street, Glasgow.

Orguinette **Music**, all the latest tunes. Price 1½d. per foot. Organina music. Orguinette, 30s. Lists free.—J. E. Wood, 1 City-road, Finsbury-square, London.

**Violins**, selected Bavarian and French, 9s. 6d. and 15s. Half usual prices. Carriage paid on approval.—Payton and Co., Importers, 127, Essex-road, London, N.

**Trouser Lengths**, 5s. each. Cheap Cloth for Ladies' Dresses, Mantles, Boys' Suits.—Hewitt, 27, Winfield Mount, Leeds. Patterns free.

**Electric Depot**, 10, Deansgate, Manchester.—Electric Breast Pins, 25s. Electric Bells, 4s. Induction Coils, 8s.—Millar, Proprietor.

Special **Amateur's List** of Castings and Finished Parts of our Motors and Dynamos, 1 stamp.—Cuttriss and Co., Leeds.

**Sheet-Iron Punchings** for laminated armatures.—Cuttriss and Co., Leeds.

**Lathes! Lathes!** Cheapest and best. List two stamps. Nothing equal at price.—Robinson, Somerset road, Sheffield.

**Notice to Woodworkers.**—At the Floral Hall, Covent Garden, the Architects' and Builders' Exhibition, March 3rd to 7th, our new patent hand and treadle circular saw, drilling, dovetailing, grooving, fret-cutting. Every woodworker should see this.—Britannia Co., Colchester.

New **Fret Saw**, with 20in. fixed arm, vertical and very rapid stroke, square wood table extends all the way, adapted for cabinetmakers and advanced fret cutters.—Britannia Co.

**Lathe Heads**, nearly new, with hardened steel mandrels and collars, 4in., 50s.; 5in., 70s. Backgeared Heads, 4in., 80s.; 5in., 98s.—Britannia Co.

**Lathe Beds Castings**, rough or planed, also all other parts. Send six stamps for catalogue.—Britannia Co.

**Foreign Correspondents** sending remittance may rely upon good value. Surplus cash returned.—Britannia Co.

**English Goods** of every description purchased and packed for export.—Britannia Co.

**Letter Copying Presses**, several nearly new, 14s. Foolscap, 38s.—Britannia Co.

**Mushrooms.** How cultivated in France. Illustrated pamphlet, translated by permission, 7½d.—J. Best, Clarence-place, Belfast.

**Electric Bell**, battery, push, and 20 yards wire, carriage free, 9s. 6d.—Franklin.

**Invalid Set Bell**, battery, pear push, stained and polished, pine case, carriage paid, 10s. 6d.—Franklin.

Wholesale **Bell and Battery** Maker, Indicators, Induction Coils. Carbons. Terminals, Wires, &c.—Franklin. Volta Works, 41, Sherman-road, Reading.

**Dynamo Wire**, 10 to 18, 1s. 6d.; 20, 22, 24, 26, at 1s. 9d., 2s., 2s. 3d. 2s 6d. lb.—Darvill, 8, Brent View-road, The Hyde, London, N.W.

**Electric Bells** at trade price; Metallic base, Platinum contacts, silk wire, post free 3s. 6d.—Harris and Co.

The **Phœnix Bell Set**, Bell, Battery, Push, and 12 yards double wire, post free 8s.—Harris and Co.

Set of **Castings** for Motor (Chaster's), 6s.—HARRIS and Co., 172, Railway-approach, Shepherd's-bush, London, W.

**Edward W. Drury**, Hull, manufacturer of all kinds of glass bottles, wire, and Chemicals.

**Electrical Machine**, 38in. plate. Height, over 6ft. Very cheap. Photo sent.—Moody Bell, Cheltenham.

**Catapults**, 7d., 1s., 1s. 2d.; elastic 2d., 3d. foot; square 1d. to 4d. yard.—Moody Bell, Cheltenham.

For sale, a fine model **Locomotive**, 3ft. 6in. long by 13in. wide, stands 1ft. 6in. high to top of boiler; all motions from footplate; it is a powerful and beautifully made engine. Price £5. Photo.—Geo. F. North, 2, Marlborough-place, Brighton.

A first-class pair Launch **Engines**, quite new, cylinders 6in. diameter, stroke 8in., steel crank, &c., stand 3ft. 6in. high by about 2ft. 1in. square, on bed plate. Price £60; cost nearly double.—Geo. F. North, 2, Marlborough-place, Brighton.

**Mica**, otherwise Talc.—RICHARD BAKER & CO., 9, Mincing-lane, London.

Write for Hindle's **List** of Electrical Apparatus, free; all parts for amateur construction.—Irwell Vale, Helmshore.

Easy **Music** for String Bands, 8d.; Band Parts, 6d —Musical Director, 39, Chapel-street, Whitehaven.

**Lathes**, several new and second-hand, from 2½in. to 8in. centres, for sale, cheap, to clear.—W. S. Brown, Halesworth.

**Lathe Parts**.—Wheels, Cranks, Standards, Beds, Headstocks.—Apply, stating wants, to W. S. Brown, Halesworth.

**Slide-Rests**, new and second-hand, from 2½in. to 8in. at greatly reduced prices to clear.—W. S. Brown, Halesworth.

**Hand Shaping Machine**, about 5in. stroke, price £4 only.—W. S. Brown, Halesworth.

**Parallel Vices** for Shapers or Planers, several very cheap.—W. S. Brown, Halesworth.

**Engines**, Boilers, &c., two or three for sale.—State requirements to W. S. Brown, Lathe Works, Halesworth.

**Dynamo** and other insulated Wires at wholesale prices. Reduced list free.—Maw, 8, Clayland-road, London, S.W.

**Gas Engines**.—1-man, £16; 1½-man, £20 cash, delivered, equal new, six months' guarantee.—Barker, Scholefield-street, Birmingham.

**Sewing Machines**, Thomas, new, cost £10 10s; offered £2 10s. Howe Leather Machines, cost £9, offered £2 5s. Singer's Medium, cost £7 10s., offered £2 10s. Exchanged if not approved.—Clayton, Magdalen street, Colchester.

**Lathe** for sale, new, six-inch centre, traversing mandrel, 5 feet bed, 6 steel screw guides, compound slide rest, hand rest and tees, by the late James Munro.—On view at J. Lewis, 2, New Oxford-street. Price £35.

**Messrs. Oppermann Bros.** beg to announce that they have the following goods for sale, prior to stocktaking, at greatly reduced prices:—One 5-light Experimental Dynamo, £7; two 12 do. do., £20 each; one 25 do. do., £30; one 34 do. do., £35; one 50 do. do., £40; one 100 do. alternating do., £70; one 300 do. alternating do., £150; one 6 arc dynamo, £60. Several arc machines of from one to four-arc lights; also some 5, 6, 7, and 8 inch double endless belt, at less than cost; and sixteen Cabath accumulators at 35s. each.—172, St. John-street, Clerkenwell, E.C.

**Lathes**, Planing Machines, Lathe Shaping Machines, Drilling Machines, Milling Machines, and various other tools.—W. R. Smelt.

**New List** of above in separate parts, rough or finished; also for machine work on lathe parts, is in preparation. Notice given when ready.—W. R. Smelt.

**Patterns of Combination Machine** in progress, comprising lathe, shaper, milling machine, slotting and drilling.—W. R. Smelt.

**Lathes and Separate Parts**, rough and finished, or with machine work done, forgings, &c. See revised list.—W. R. Smelt.

**Turning, Boring, Screw-cutting**, Planing, Forgings, Patternmaking, to order. Models for inventors and patentees.—W. R. Smelt.

Send 1 stamp for **Revised Lathe List**.—W. R. Smelt, Engineer, 7, Goldsmith's-row, Gough-square, E.C.

Separate **Pedal Organs**, for harmoniums and American organs, from £3.—G. Fryer, 17, Richardson-street, Swansea.

**C. Pilkington**, 32, Sackville-street, Piccadilly, W., Magic Lantern Artist and Photographic Colourist.

Magic Lantern **Photograph Colouring**, finely and artistically done, 12s. per dozen. Special terms to the trade on application.—C. Pilkington, 37, Sackville-street, W.

**Castings**.—Half horse-power, Vertical, Horizontal, or Launch Engine Castings, ports in cylinders. Complete sets Castings and Forgings, 12s. 6d. One horse power, 25s.—Tomlin, Highfield terrace, Barnsley.

**Castings**.—Bench Drilling Machine Castings, 3s. 6d. set. ;small Brass Engine Castings, 2s. 6d. set.—Tomlin, Highfield-terrace, Barnsley.

**Castings**.—Half horse-power, 9s. 6d. set, ports in cylinders, horizontal, launch, or vertical. Send for price list, designs and particulars of perfected castings, free.—I. Tomlin, Engineer, Highfield-terrace, Barnsley, Yorkshire.

**French Polishing**, Staining, Varnishing, and Painting. 122 receipts or trade secrets, with full instructions and details, free 1s. (Genuine.)—I. Tomlin, 23, Highfield-terrace, Barnsley, Yorkshire.

**Microscopes and Apparatus**.—R. G. Mason (from J. Swift), manufacturing Optician to the trade; Binocular Microscopes, Stand, and Stage Condensers, Spot Lenses, Polariscopes, and other apparatus. Repairs and alterations. All kinds of mounting materials.—24, Park-road, Clapham, London, S.W.

"**See-saw**" **Waltz**, 4s.; reduced price, 1s. 6d. post free.—William Lea, 50 and 52, Church-street, Liverpool.

"**Hypatia**" **Waltz**, 4s.; reduced price, 1s. 6d. post free.—William Lea, 50 and 52, Church-street, Liverpool.

20s. worth of best **Songs and Pieces**, post free, 1s. 2d.—William Lea, Church-street, Liverpool.

**Pattern Making**, every description. Estimates free.—J. Bostock, General Pattern Maker, Park-street, Derby.

"Home" **Washer and Mangle** combined, never used, cost £6 6s., sent free £4 4s.—Bostock, Park-street, Derby.

**Chemicals and Apparatus** at lowest prices. Stamp for reply.—Greenwood, Chemist, Lozells, Birmingham.

Loughboro' Dry Plate Company's **Instantaneous** or Rapid Emulsion, 8s. 6d. pint; ¼-plates 18s. gross, with instructions. Carriage paid. Splendid quality.—302, Coldharbour-lane, S.W.

**Lathe**, back-geared slide and surfacing, 14½in. centre, by 2ft. bed, £21.—79, Dudley-road, West Bromwich.

Combined **Engines and Boilers**, 2, 2½, and 3-horse, low prices.—79, Dudley-road, West Bromwich.

Bateman's 2½in. **Astronomical** (achromatic), nearly new, four eyepieces, garden stand, cost 95s., price 35s.—Below.

**Engine and Boiler**, cylinder 2in. bore, 3½ stroke, good condition. Photo, 2 stamps. 32s.—Below.

**Microscope**, four powers, capital instrument, 28s.; cost 63s. Stamp reply.—Robson, 73, Rosoman-street, Clerkenwell, London.

**Parts of Tricycle**, rubber-tired wheels, roller bearings, &c.—Wallace, 33, College-street, Liverpool-road, N.

**Brass Name Plate**, 9 by 4½, engraved plain or fancy, 4s. 6d., carriage free.—E. F. Broadbent, Grenfell-avenue, Maidenhead.

**Name Plates** for bags, 1in. by 3in.; name, 1s.; name and town, 1s. 6d.—E. F. Broadbent, Grenfell avenue, Maidenhead.

**Zephyr Tricycle**, by Richardson, Ellison, and Co., Coventry, ball bearings, never been used; cost £21, price £12.—Apply H. P., East Howle, Ferryhill.

**The Kinetic Engineering Company**, 36 and 37, Brooke-street, Holborn, London. Circulars and list post free.

**Dynamo Wire**, 1s. 2d. per lb. Line Wire, 29s. 6d per mile. Pushes 4s. per dozen.—Kinetic Company.

**Leclanche Cells**, best. No. 1, 16s.; No. 2, 19s.; No. 3, 22s. 6d. per dozen.—Kinetic Company.

**Electric Bells**.—Best quality, workmanship, appearance, and value in market, 40s. per dozen.—Kinetic Engineering Company.

**Maiche Patent Battery**.—Best yet produced. Circulars and Scientific Reports post free.—Kinetic Engineering Company.

**Electrical Supplies** of all kinds.—KINETIC ENGINEERING COMPANY, 36 and 37, Brooke-street, Holborn, London, E.C.

**The Comprehensive Astronomical Map**, containing the stars visible in Britain, with indicator. Paper, 1s. Cloth, with cases, 2s.—Archibald and Peck, Hanover-street, Edinburgh.

**Microscope** for sale, largest size binocular, Ross pattern; Microscope by Swift, in perfect order; Mechanical Stage; also sub-stage, with Swift's £4 achromatic condenser, with diaphragm apertures, spot discs, and polariscope; pair of A eyepieces, also E eyepiece, stage forceps; Wallaston Camera Lucida, large bull's eye condenser, on stand, double nose-piece, ⅛in. objective; all in good mahogany case; price £16.—Dr. Collins, East Grinstead, Sussex.

**Electric Motor**, in perfect condition, having only been used two or three times; will drive easily large sewing machine, fret saw, or small lathe, 15s. English Mechanic, 2 vols., complete, 1883 and 1884, 4s. each.—W. Pennell, Gowt's-bridge, Lincoln.

**Dynamo Machine**.—For sale, a Bottone Dynamo Machine, in perfect working order, large strong driving wheel, highly finished, nickel-plated parts, quite new, price £3 10s Shop price, £7 7s.—Address, Lowe, 11, Wills-street, Lozells, Birmingham.

Splendid **Foot Lathe**, 5½in. centre, 4ft. gap bed, sliding, surfacing, screw-cutting, six speeds, and roller bearings. Quite new, and has never been used. Such a substantial and well-finished tool is rarely to be met with at the price, viz., £30. —Phillips, Chambers, and Co., 62, Holborn Viaduct, London, E.C.

**Brass Door Plate**, 9 by 4, engraved in any style, 4s. 6d.—Deacon and Son, General Engravers, Ramsgate.

**Anemometers**, all metal, good, free for 48 stamps. —A. C. Bell, Metallurgist, Main-road, Bexley Heath.

"**English Mechanic**," Vols. III. to XXXIX., cloth lettered, 40 Nos, 1—14; "Academy," Vols. I. to XXV., cloth lettered, Vol. XXVI. in Nos.; "Athenæum," 31 half-yearly vols., cloth lettered, Jan. 1869 to June, 1884, and July—Dec., 1884, in Nos. All clean. Offers.—L., 30, North Villas, Camden-square, N.W.

"**English Mechanic**," first 32 volumes, complete, 32s.—W. Schofield, 32, King-street, Droylsden, Manchester.

**Lathe**, 3½in. centre, 3ft. planed bed, turned flywheel, rest, face-plate, die and other chucks, carrier's tool board, &c., £4.—Robinson, 22, Osborne-road, Finsbury Park.

New 4in. screw-cutting **Bench Lathe**, first-class tool, 10 guineas.—A. Halls, Howard-street, Yarmouth.

**Gold Fish**, 1s. pair. Tench, 6d. pair. Aquatic Plants. Snails, 8d. doz.—Samuel Newton, Short-hill, Nottingham.

**Battery**, bichromate, highest electrical efficiency, Contains 10 per cent. more chromic acid than potash bichromate, Lee's new double Bichrome. Soluble in own weight water. 7d. lb., 7lb. parcels. 6½d. lb. in 56lb. lots.—R. A. Lee.

**Dynamo**, 10-light, continuous working, patent disc, armature. Low speed. Requires ½ h.-p. to drive. £15.—R. A. Lee.

**Dynamo**, 20-light, as above, requires 1 H.-P., £28. Ditto, 30 lights, 1½ h.-p., £39.—R. A. Lee.

**Motor**, Lee-Chaster Patent, half h.-p., splendidly finished, for driving gentlemen's lathes. Requires small battery power. £16.—R. A. Lee.

Lee's Patent Primary **Battery** for above, or lighting 6 incandescent lamps. £3 10s.—R. A. Lee, 76, High Holborn, London, W.C.

Chaster's **Electro-Motor Castings**, 3s. 6d. set. As described in "E. M.," 1026, 1027, and 1029.—R. A. Lee.

Chaster's Patent **Electro-plating Apparatus**, Nickel, Cobalt, Silver, price 63s. Send stamp for particulars.—R. A. Lee, 76, High Holborn, London.

12in. Surveyor's **Level**, nearly new, fitted with Hoffman's Patent Tripod Head, in perfect adjustment; cost £16, price £10.—D., 3, Bampfylde-street, Exeter.

Valuable Hearder's **Intensity Coil**, 3in. spark, cost £10, price £4, or offers.—Ernest Clover, Springfield, Sudbury, Suffolk.

**Gas Engines**, 1, 2, and 4-man. Simple and strong. Numerous references.—Ellis Butterworth, Rochdale.

**Microscopic Objects**.—A quantity of good mounts to be sold cheap.—White, 17, York-street, Nottingham.

**Stammering**.—The "Suophone," a mechanical appliance singularly serviceable in overcoming this distressing habit, with instructions for use, 13 pence.—Mr. Rysott, Cliff-road, Southampton.

Barrel **Piano**, polished mahogany, eight tunes, suit gentleman's nursery, 35s. First 17 2s. numbers "Cassell's History of England," illustrated, 8s.—Gunstone, South Petherton, Ilminster.

**Force Pumps** for testing or feeding model boilers 5s.—J. Leech, South View, Hayfield, Stockport.

The "**English Mechanic**," from 1879 up to the present date, uncut, unbound, with indices, take 30s.—Wm. Masters, Heypond, Weedon.

**Snider Rifle**, perfect condition, Government sighted, &c., price 30s. Bargain.—J. J. T., Alexandra Rooms, Cambridge.

Model **Engine Castings**.—Horizontal, Locomotive, Vertical, Beam, and Marine. List, stamp.—Wood, Dalley-street, Broughton, Manchester.

Rare bargains.—**Stereoscope Camera**, with dark slides, changing box, and Ross lens, £4. Cabinet Rolling Press, 12s. 6d.—P. Feathers, Dock street, Dundee.

"**Chambers's Encyclopædia**," 10 vols. for sale, nearly new, cost five guineas.—E. O., 7, Newland-road, Worthing.

**Microscope Objectives**.—A 3in., 1in., ⅛th, ⅛th, 1-12th water immersion, good English lenses, to be sold cheap.—E. S., 105, Myddleton road, Hornsey.

Two sculpture Solograph **Lantern Slides**, as samples free, 1s. 9d.—Solograph Co., Church-green, Guisboro.

Forward **Negatives** and have your Lantern Transparencies made for 9d. by Solograph Co., Church-green, Guisboro

Solgraph **Lantern Transparency** and three Solgraph dry plates, free 1s. 3d.—Solograph Co., Church-green, Guisboro.

**Marqueterie Friezes** and Panels, high class.—Seen at Mr. Lees, 3, Camden Cottages, Camden-road, London.

"**Bedford Catalogue**," "Smyth's Celestial Cycle," complete, good condition.—A., 3, Camden Cottages, Camden-road, N.W., London.

**Circular Saw**, superior treadle, second-hand.—Apply to Allen Lee, 3, Camden Cottages, Camden road, London.

Two **Dynamos**, 5 and 10-light, new. Particulars stamp.—Warne, 55, Great Suttor street, E.C.

**Lathe**, Selig, Sonnenthal's, 10 guinea, 5in., 4ft. bed, little used, perfect, £8 10s.—Letter to H., 9, Holborn Viaduct.

Extra Refined **Benzoline**, 10d. Royal Daylight, 7d. Crystal Oil, 6½d. per gallon.

**Stylographic Pens**, 2s. each, postage 2d.; usual price 5s.—H. Jones and Co., Viaduct street, London, E.

**Gas Engines**, simple, cheap, and reliable, ½ M.-P. to 1 H.-P.—W. and J. H. Hill, York.

**Photographs**, Scottish scenery, 7 by 4, extraordinary value, 4d. each.—Address, Photo, 182, Trongate, Glasgow.

Clear **Gelatines** for tracing magic lantern slides, 4½d per doz. films.—Photo, 182, Trongate, Glasgow.

Fine-toned **Violin**, labelled "Jacobus Stainer in Absom prope Oenipontum, 17—" with bow and instruction book, 30s. Bargain.—Beaumont, Wonersh, Common, Guildford.

Bench **Lathe**, 2½ centre, on wooden stand, complete, 25s.—Address as above.

**Sewing Machines**, Laundry Appliances, &c. Any maker's stock for disposal. Offers for lot or one.—99, Marne-street, Queen's Park, W.

**Important Notice**.—Try one of my Hollow-Ground razors, warranted. Will be exchanged if not approved of. Post free 1s. 4d.—Address as below.

**Notice to Hairdressers and Others**.—Where to get your scissors and razors carefully ground by London and Sheffield workmen. Scissors ground, 3d. per pair; razors, 2d.; ground and set, 4d. Can be sent by parcel post. Two prizes awarded for the manufacture and excellence of workmanship. Established 1804.—W. S. Mundy, Cutler, Greenwich, S.E.

For sale, Horizontal **Engine**, stands on hot well, two cylinders, 1½ by 3in. stroke, reversing gear and pump. £4.—Jas. Cunningham, 26, Mary street, Southwick, Sunderland.

**Roughened Glass**, a large quantity cut up to 24in. by 8in. by 3-16in. thick, been used. What offers? Cash required. Joe Blain, Carlisle.

**Water Motors**, for sewing machines, organettes, window advertisements, 32s., 42s. List one stamp.—Wheeler.

**Fan Castings**.—Improved Registered Designs; sets 8in., 3s.; 6in., 4s.; 8in., 5s. Drawings, 4d.—Wheeler, Engineer.

**Water Motors**.—Complete one horse-power, £9. Half, £6. Quarter, £4. Eighth, £3.—Thomas Wheeler. Preston.

**Motor Castings**, materials for Electric Bells, Batteries, Galvanometers, Intensity Coils, Microphones.—King, Mendham, and Co., Bristol.

**Insulated Wire Table**, showing size, weight, resistance per foot, feet per ohm, &c., price 3d.—King, Mendham, and Co., Bristol.

**Standard Ohm**, in box, copper poles, guaranteed correct to ten thousandth of ohm, 21s.—King, Mendham, and Co., Bristol.

**Wimshurst Influence Machine**.—Sole Manufacturers of Improved Pattern. Numerous testimonials as to thorough efficiency.—King, Mendham, and Co., Bristol.

**Galvanometer Cards**, improved for tangent and ordinary combined, 2½in., 8d.; 4in., 10d.; 6in., 1s.; post free —As Above.

Write for **King, Mendham, and Co.'s** large new and reduced Price List, post free 4 stamps.

**Drilling Machine**, 25s., fast and slow speeds, cheap and very good.—F. Parker, Farndon-road, Oxford.

**Books**.—"Mechanic's Workshop Companion," 5s. 6d.; "Engineer's Machinist's Practical Assistant," 2s. 9d., per post.—E. F. Baldwin, Robinswood-hill, Gloucester.

Steel **Name Stamps**, 3d. per letter. Figures (set), 2s. 4d. Letters, 6s. 4d., per post.—E. F. Baldwin, Robinswood-hill, Gloucester.

**Name Burn Brands**, 5d. per letter. Indiarubber Name Stamps, 1s. 8d. per post.—E. F. Baldwin, Robinswood-hill, Gloucester.

Improved half-horse **Water Motors**, suitable for driving amateurs' lathes; very strong; £4 10s.—Muncaster.

Complete set of **Castings** for above, including all bolts, shaft, &c., 37s. 6d. Litho and particulars, 6d.—F. Muncaster, 34, East View, Preston.

**Dynamo Castings** (Mr Bottone's), 6s. set, comprising field magnets, armature, standard, brass armature plates, brushes, trunnions, and brass bearings.—E. and T. Wiselit, 29, Loyd-street, Leeds, Yorkshire.

**Bicycle**, 52in., latest improvements, perfect condition, price £8.—For particulars apply to J. S. Bonnard, 18, Holgate-road, York,

**Cyanotype Paper**, 4d. per sheet. Specimen free.—Humphries, 5, Esher Villas, Shadwell-road, Holloway, London, N.

1½-horse Vertical **Engine and Boiler**, complete, good as new, cheap.—Vincent, Cheylesmore, Coventry.

New **Horizontal Engine**, 2½in. cylinder, 5in. stroke, turned fly wheel, £3 10s.

Pair of **Marine Engines**, about 1¼in. cylinders, 1⅝in. stroke, cost £4 short time since ; price 35s.—W. Potter, 2, New-street, Preston.

Horizontal Steam **Boiler**, ⅜in. plate, 4ft. by 1ft. 9in., safety valve, water gauge, and pipes, £4.—Somerset House, Walton-street, Stapleton-road, Bristol.

**Induction Coil**, 1in. spark, splendid make, nearly new, with condenser, complete, £2 10s —As above.

**Chemical Retorts**, Bulbs, Test Tubes, &c. One-third list prices.—As above.

Bunsen **Battery**, four pint cells, in wood case, good as new, 10s.—E. Thornton, Barrow-in-Furness.

For sale, the last four years' "**Proceedings of the** Institution of Mechanical Engineers."—Address, 62, Dryden-street, Nottingham.

"**English Mechanic**," any back number 3d. each Vols. 3s. 9d. Postage extra.—Sladen, 33, Cank-street, Leicester.

Fine old concert **Violin**, labelled "Antonius Stradiurius, Cremona faciebat, anno 1680," marvellous rich tone, fine condition, with silver mounted bow, take 8s. 6d., carriage paid. Excellent machine head guitar, 9s. 6d.—Carr, Bicycle Agent, Brightlingsea.

Canadian Gold Geneva **Watch**, a real beauty, equal new, price 10s. 6d. Bargain.—Thomas Carr, Brightlingsea, Essex.

**Electric Bell**, 3s. 6d. Leclanche Battery, 2s. Bichromate, 3s. Ruhmkorff Coil, 6s. Other apparatus cheap.—Buntine, Didsbury.

**Formulas Worked Out** for winding Dynamos and motors from 10 c.-p. to 500 c.-p., 14 stamps. Drawings and Diagrams from 5s.—H. Jones.

**Dynamos**, patent improvements, No. 2,122. 70 c.-p. machines, £5. 32 volts, 7 ampères.—H. Jones.

**Dynamos**, best small machines in the trade, and cheapest double-covered Wires to 20 gauge, 1s. 8d. lb.—H. Jones.

**Motor Castings** (model 5-light dynamo), laminated armature, 20 per cent. better than solid. 3s. a set.—H. Jones.

**Dynamos** for Home Lighting.—5 lights, or arc of 500 c.-p. Price £6 10s., approval. Warranted.

**Dynamo Castings**, with laminated armatures, 8 c.-p., 5s. ; 16, 5s. 6d. ; 20, 6s. 6d. ; 30, 7s. each.—H. Jones.

**Dynamo**, laminated armatures, no heating, ventilating ; 70 c.-p., 16s. a set ; finished, £5. Warranted.—H. Jones.

**Dynamo Machines Repaired.** 100 c.-p., 9s. Motors, with wire, 6s. 6d.—H. Jones, 48, High-street, Lambeth, S.E.

**Incandescent Carbon Lamps**, low resistance, 3s. each ; Fairy Lamps, 3s. 6d. ; Platinum Lamps, 1s. 3d., post free.—Todd, 14, Wentworth-road, Manor Park, Essex.

**Incandescent Lamp Holders**, new pattern, best in the trade, 12s. dozen ; sample, post free, 1s. 3d.—Todd, as above.

**Launch Boilers**, 6in., 4½in., and 3in. bore, vertical and horizontal boilers, propellers, &c.—S. Smith, 11, West-street, Soho, W.C.

Model **Steam Engines** made or repaired. Separate parts fitted up, boilers made to order.—Lucas and Davies, 21, Charles-street, Hatton-garden, London.

Good **Tricycle** for sale, back steerer, ball bearings, new 18 months ago. £5 10s.—29, Mill-lane, Warrington.

Hardy British **Ferns**, including Aspleniums, Lastreas, Polypodiums, Bladder Ferns, Athyriums, Scolopendriums, Blechnums. 14 free, 1s. 3d. 20 large Rockery Roots, 2s. Fifty, 4s. 6d. 100, 8s. Botanically named, carriage paid.—John Burns, Fellside, Kendal.

**Gordon.**—Solid Bronze Bust of this Great Hero, five inches high. Post, 18 stamps.—Neil, 22, St. David's-street, London, S.E.

**Gordon!** Gordon!! Gordon!! Solid Bronze Best per post, 18 stamps, free.—Neil, 22, St. David's-street, S.E.

**Type** for sale, cheap, several jobbing founts, presses, chases, &c. Specimens, 1 stamp.—Clark, Watchmaker, Spennymoor.

Half-plate **Portrait Lens**, good as new, complete with diaphragms, 30s.—W. J. Brown, 36, Tything, Worcester.

**Pipe Organ**, 4 stops, 212 pipes, wood and metal, one octave pedals.—J. Balmer, 10, Hanmer-street, Darlington.

**Cheap Printing.**—Bill Heads, 6s. 1,000 ; Memos. 5s. 6d. Business Cards, 6s. 6d., carriage paid.—Brooks and Co., Rotherham.

Amateurs and the trade supplied with **Dynamo** Castings and every description of wire for electrical purposes at lowest possible rate. Dynamo Castings machined and fitted ready for winding. Dynamo machines repaired.—Ashby.

Gramme **Dynamo Machines**, sound and well made, suitable for lighting shops, &c. Expressly made for long running; long bearings, massive fields ; 120 candle power, £6 10s.—A. Ashby, 184, King's-road, Chelsea.

**Engineer's Taps.**—¼in., 1s. 1d. ; 5-16in., 1s. 2d. ; 3-8in., 1s. 3d. ; 7-16in., 1s. 4d. ; ½in., 1s. 6d. ; 5-8in., 2s. 0d. ; ¾in., 2s. 6d. ; 7-8in., 3s. ; 1in., 3s. 6d.—Jermy and Son, North-street, Stafford.

Circular **Stocks and Dies**, for cutting a full thread at once running down. Lists, 1 stamp.—Jermy.

**Stocks and Dies**, warranted quality, Whitworth and ordinary angular patterns. — Jermy and Son, North-street, Stafford.

**Patent** (valuable Electric). Great Novelty.—Sale Department, International Inventors' Co-operative Patent Agency, Outer Temple, London.

**Ventriloquism.**—How to acquire this wonderful art. Success certain. Never fails. 7 stamps.—See below.

Fac-simile **Copying Press**, Instructions to make, cost few pence, prints hundreds of one copy, 7 stamps.—Below.

**Recipe** for Self-shining Waterproof Blacking, 7 stamps, genuine and inexpensive.—See below.

**Rubber Stamps.**—Make your own ; costless ; full instructions, 7d. All four 1s.—G. Marquis, Allhallow-gate, Ripon.

**Watch Repairs.**—New Cylinder, pivoted, 2s. 6d. Pivot, 1s Stamp for list.—J. King, Watchmaker, Briggate, Leeds.

**Drawings, Tracings**, &c., for Inventors, cheap and good. — Drawing Department, Co-Operative Patent Agency, Outer Temple, London.

**Gas Engine** for sale, quite new, in very good order. Never been used. Cylinder 10in. by 3½in. What offers ?—Purvis, Brompton Barracks, Chatham.

Pair second-hand **Telegraph Instruments** (pedals), in good working order, complete, with two Leclanche Batteries, £3.—J. B., 13, Station-street, Sittingbourne.

12in. **Sextant**, by Troughton and Simms, for astronomical and other purposes ; cost £25. Price £10 10s.—S., 20, Montpellier-road, N.W.

Dollond **Telescope**, 4in., quantity apparatus, in case, cost £75 ; price £25.—S., 20, Montpellier-road, N.W.

Canoe **Gas Engine**, generates its own gas while working. Complete Castings, 50s. Working Drawing, 5s. Litho, 4 stamps.—A. Dorrington, West Gorton, Manchester.

The Amateur's **Gas Engine**. Simple and compact. Castings, 42s. Drawing, 5s. Litho, 3 stamps.—A. Dorrington, West Gorton, Manchester.

Double-cylinder **Gas Engine**, impulse twice every revolution. Castings, 90s. Litho, 3 stamps.—A. Dorrington, West Gorton, Manchester.

Half horse-power Horizontal **Engine Castings**, ports in cylinder, 12s. 6d. Drawing, 18 stamps. Litho, 2 stamps.—A. Dorrington. West Gorton, Manchester.

The Amateur's **Drilling Machine**. Castings, 3s. 9d. Forgings, 3s. Drawing, 8 stamps.—A. Dorrington, West Gorton, Manchester.

No. 2 **Drilling Machine**, self-acting feed motion. Castings, 7s. 6d. Forgings, 5s. Drawing, 18 stamps.—A. Dorrington, West Gorton, Manchester.

Launch **Engine Castings**, 2in. cylinder, 12s. 6d. ; 3in., 26s. ; 4in., 50s. ; 5in., 70s. Litho, 3 stamps.—A. Dorrington, West Gorton, Manchester.

4½in. **Fan Castings**, 3s. 6d. per set. Drawing, 4 stamps.—A. Dorrington, West Gorton, Manchester.

3 or 4 jaw **Chuck Castings**, 3s. Forgings, 1s. 2d. Drawing, 6 stamps.—A. Dorrington, West Gorton, Manchester.

3in. back-geared **Lathe**, 2ft. 6in. bed. Castings, 14s. 6d. Drawing, 18 stamps.—A. Dorrington, West Gorton, Manchester.

Model Horizontal **Engine Castings.** 1⅛in. by 2in. cylinder, 6s. Drawing, 12 stamps.—A. Dorrington, West Gorton, Manchester.

**A. A. D.** guarantees his Castings as soft, sound, and strong, and his prices as low as possible consistent with good material. Enclose stamp for list.—A. A. Dorrington, West Gorton Foundry, Manchester.

**Universal Trade and Amateur Supply.**—Lecture requisites ; light, heat, air, water, geology, engineering, chemistry, photography, &c. Wholesale and export.—Caplatzi.

Frictional and **Induction Machines**, Plates, Cylinders, Stands, Conductors, Glass, Vulcanite. Hundreds of Lecture Accessories ; their Parts.

**Coils.**—Experimental, Resistance, Medical, Dynamo, Bell, Telegraph, Galvanometer, and other purposes. Vacuum Tubes.

**Batteries.**—Thousands Lighting, Experimenting, Medical, Depositing. The Universal Four-cell Case, 18s. Convenient, durable, and economical.

**Dynamos**, Arc and Glow Lamps, Electric Lanterns, Castings. 10 kinds of Motors, Leads, Armatures, Dynamometers.

**Wires.**—Cheapest Stores. New and second-hand. Great reduction in price. Paraffin, Vulcanite, Reels, Brasswork, Cores, various.

**Astronomy.**—"Society's Monthlies," number good Stands, Tubing, Clock Racks, Circles, O.G.'s, Eyepieces, Finders, Prisms ; other parts.

**Transit**, 2½in., by Cary, with circles ; good 2, 2½, 3 Telescopes. Several Reflectors ; great variety of Terrestrials.

**Microscopes.**—Fine 3-power, Mechanical Stage, Polarising Ross, £9. Many others, £4, £5, £6. Unrivalled cheapness.

**Surveyor's Levels**, Perambulators, Prismatic Compasses, Sextants, Drawing Instruments, &c.

**Lenses**, Prisms, Specula, Object-Glasses, Eyepieces, Finders, Cells, Tubing, Racks, Hooks, Joints, Optical Glass, Tools, in quantities.

**Machinery.**—Several good Lathes, Litho, Printing, Stamping Presses, Flatting Mills, Wheel-cutting Engines, Swiss Mandrels, Wire-Covering Machines.

**Model Engines** to 2 H.-P. Great number of 1, 2, 3in. stroke ones ; good boilers, cylinders, gauges, wheels, cocks, pumps, boats.

**Boilers.**—Copper, Iron, Boat, Locom., Bath, Kitchen Range, Distilling, Vapour Bath, Testing Pumps, Gauges, Fittings.

**Lathes.**—Overhead, Ornamental, 20 ; Brassfinisher's, 7 ; Amateur's 3in., 5 ; Combination, with Fret and Circular Saw, £4.

**Wheels.**—Fly, Lathe, Saw, Engine, Dynamo, Gearing Pulley, Clock Movements ; Large Springs, Bearing, Shafting, Standards, various.

**Screws and Bolts** for Machinists, Model Makers, 160 sizes. Sample 50, 1s. Screw Plates, Taps, Chasers, Stocks.

**Magic Lanterns**, Slides, Microscopes, Kaleidoscopes, Oil and Lime Burners, Retorts, Bags, Bottles, Condensers, Lamp Reflectors, Lantern Bodies.

**Lenses**, Oil and Lime Lights, Gas-making and Storing Apparatus, for hundred lanterns. Small, large, and Photo-enlarging Lanterns.

**Slides.**—Superior painted, comic and effects, Scientific, immense selection. Skilled exhibitors for town and the provinces very moderate.

**Prisms**, Nicols, right angle, Spectroscope, Camera, Lucida, Obscura, Bisulphide, Achromatising, Cylindrical Lenses. Polarising Plates, various.

**Presents.**—50 Microscopes, 100 Accessories, Objects, Cabinets, Powers, Condensers, Stands, Books, exceptionally low prices—2s.-£10.

**Chemistry.**—Fittings-up of complete Laboratories, Copper Troughs. Gasholders, Stills, Baths, Porcelain. Many Balances, Platinum, 2-thirds price.

**Purchases** and Valuations. Fair trade value. Cash by return, or best selling market indicated. Particulars first.

**Hire.**—Occasional Lecturers and Bazaars will receive good terms, many facilities, with Apparatus of all kinds.—Caplatzi.

**Catalogue, 2d. Caplatzi**, Science Depot, Hire and Exchange, Chenies-street, Tottenham-court-road, near British Museum.

**Instruction in Glass-blowing.** Vacuum pumps, high vacua tubes to order.—H. Newbold, 25, Calthorpe-street, W.C.

**Oxygen Gas**, compressed in cylinders, handiest and safest for limelight. — Clarkson, Compressed Gas Chemist, Bartlett's-buildings, E.C.

**Oxygen Gas**, compressed into iron bottles, liquid nitrous oxide and carbonic acid.—Clarkson, Compressed Gas Chemist.

**Oxygen Gas**, compressed into iron bottles ; prices on application.—Clarkson, 28, Bartlett's-buildings, Holborn, E.C.

**Brassfinishing**, Lacquering, Bronzing. Old Work re-lacquered or bronzed equal to new.—A. E. Knight, 12, Albert-street, Paddington-green, and 25, Harcourt-street, Marylebone-road, W.

**Hydraulic Press** (second-hand) wanted, with platen about 8in. dia., either circular or square, ram about 3in. or 4in. dia., rise about 6in. or less between platen and head.—Address (letters only) H. B., 2, Birdcage-walk, Stamford-hill, N.

**Fretwork Patterns.**—Book containing over eighty good full size patterns. Testimonials on application. 1s. 2d.—S. Brockway, Marlborough.

## Wanted.

Agents Wanted.—Morgan's celebrated Improved Scale-Preventing Compound. Nothing better or cheaper.—W. H. Morgan, Engineer, Gloucester.

Old Microscopes, by Adams, Amici, Baker, Dollond B. Martin, Pritchard (Goring's "Engiscope"). Varley, and other old makers.—J. Mayall, Junior, 224, Regent-street, London, W.

Wanted, T-rest for 4½ Lathe ; also hand Drilling Machine, drill up to ½in., with drills.—C., 6, Oakfield-place, Clifton, Bristol.

Wanted, piece of well-seasoned Straight-grained Greenheart, 7ft. long by 3in. by 1⅜in.—Price to J. S., Holly Bank, Budleigh Salterton.

Wanted, small Observatory for 5½ft. telescope ; must be cheap and easily removable. State lowest price.—T. H. G., Mackay's Library, 185, Albany-street, Regent's Park.

Platinum Wanted, 18s. to 20s. per ounce given. Old crucibles, foil, spongy platinum, &c.—Berkley, Auchenhove, Lumphanan, Aberdeenshire.

Wanted, second-hand 7in. screw-cutting Lathe, also 1 h.-p. Engine and Boiler.—Jenkins, 30, Langdon-place, Swansea.

Wanted, "Model" Printing Press. Guaranteed in perfect order.—287, Crystal Palace road, London, S.E.

Wanted, Electric Bell with Fittings, under 4in., Dome, Battery, and Switch, cheap.—D. J., 56, New Kent-road, London, S.E.

Wanted, Vols. XXXVII. and XXXVIII. English Mechanic, unbound. State price.—Jos. Kilburn, North Bondgate, Bishop Auckland.

"United States" Business Directory (recent). State price to Furnival, Bucknall New-road, Hanley.

Wanted, Inventors to send particulars of Inventions for sale.—Inventors' Co-operative Patent Agency Outer Temple.

Deer Horns Wanted.—M. Day, Hook and Handle Manufacturer, 56, Driffield road, Old Ford, London.

## Addresses.

To "Invicta."—For "Jay Jay See," address J. J. Cain, 33, Albert-street, Millom, Cumberland.

"Condensation on Galvanised Roof" (55520) and "Stove" (55798) should write—T. Pallister, 79, George-road, Newcastle-on-Tyne

Wanted, address of Split Pin Manufacturers.—W. Morley, 65, Walmer road, Plumstead. Kent.

Would "Backwoodsman," who replied to query 5482, kindly forward his address to 86, Southampton-street, Reading ?

Hæmorrhoids.—Will "Jeroom" kindly send Ointment (enclosing his address) to B. J., The Rowans, Rowley Park Stafford ?

## Situations.

Medical Electricity, Magnetism.—Assistant required, with practical knowledge, Christian Home, progressive salary.—Devon Electropathic Association, Plymouth.

**18c. HEAVY ROYAL GOLD SOLID WATCH CHAINS, LADIES' or GENTLEMEN'S.**

In order to secure new customers for goods of our own manufacture, we will forward, post paid to any address in the United Kingdom, one of our Heavy 18c. Royal Gold Solid Watch Chains, at a merely nominal price, on condition that you show same to your acquaintances and distribute the Catalogues we send with it. You can in this way assist us in selling other Jewellery of STANDARD QUALITY, GUARANTEED TO GIVE SATISFACTION, and upon which we look to make our profit. A small sum of money and a little labour will thus enable you to obtain a Valuable Article of Jewellery.

We can only send out a limited number of Watch Chains at the price named below, and to protect ourselves from Jewellers and others ordering in quantities, not more than one Chain can be posted to any one person ; but after you order and others are required, we will sell you any number of 18c. SOLID GOLD WATCH CHAINS, by weight, at the rate of 84s. per ounce, and which you will have no difficulty in disposing of at a good profit.

No. 1. Lady's Solid Watch Chains (nearly 1½ yards long), 2s. or 26 Stamps.
" 2. Gent's Solid Single Albert, 1s. 3d. or 16 Stamps.
" 3. Gent's Solid Double Albert, 2s. or 26 Stamps.
" 4. Lady's Solid Necklet, with ring and drops complete, 2s. or 26 Stamps.

Warranted Newest and most Fashionable Patterns.

You will find nothing more appropriate to give, if you wish to make a Wedding, Birthday, or other present, than our truly beautiful goods. Our Company is old established and reliable, and only good articles are sold.

H. Newcombe, of 27, Northumberland-place, Teignmouth, writes: "Much pleasure in acknowledging chain, with which I am agreeably surprised and pleased."

Please remit where possible, by P.O.O., payable to M. Green. All orders by post sent off at once. Kindly name this paper in your letter or order.

**THE CROWN JEWELLERY COMPY.,**
12, CATHERINE ST., STRAND, LONDON, W.C.

---

**HARMONIUM and AMERICAN ORGAN** FITTINGS of every description. Esteves, best quality, 12s. 6d. per set Turban and Co.'s celebrated Reeds, 10s. Voicing, 2s. set extra. Pans, Bellows, Keys, &c. Complete List, Stamp.—W. HANDS and CO., Organ Builders, Bedford.

---

**£20 TOBACCONISTS COMMENCING.**—"A Pamphlet" (80 Pages), HOW TO COMMENCE BUSINESS RESPECTABLY from £20 to £500, 3 stamps.—H. MYERS and CO., Cigar and Tobacco Merchants, 109, Euston-road, London. Wholesale and Export Only. Telephone No. 7541.

## COMPLEXITY IN MACHINERY.

IT is often asserted that a piece of machinery or apparatus is "too complicated," and therefore not to be trusted; but if the judge who thus glibly condemns is subjected to a little cross-examination, it is soon discovered that his idea of complexity will not bear a critical examination. It is a demonstrable fact that with the progress of invention, and for that matter, of civilisation itself, machines have tended to become more complicated, but this very complication is a proof of their greater efficiency; for, otherwise, the law of the survival of the fittest would have relegated them to the scrap-heap. When, then, we hear a piece of apparatus condemned because it is apparently complicated, we must first determine what is meant by the term; and, secondly, whether the parts of the machine are really so entangled together as to lead to frequent derangements. A locomotive may be taken as an instance of so-called "complicated" apparatus; but it is matter of common knowledge that it is an efficient machine, and no one now ventures to speak of it as "too complicated." The subject was brought prominently forward at a meeting of the Society of Arts last week, when Mr. Hiram Maxim described his wonderfully complex automatic gun, and Prof. H. S. Hele-Shaw read a paper on the evolution of machines. With an increase in the number of parts in any given apparatus there is necessarily an increase in the number of points at which failure may possibly occur; but the doctrine of evolution applied to machines shows that increased complexity is simply a synonym for increased certainty of action. Prof. Hele-Shaw has compiled a table showing the number of parts belonging to the propelling machinery of a first-class Atlantic steamer, and very formidable the figures look in that shape, when we find that the engine has 6,000 separate pieces, and count up all the bolts, nuts, pins, rivets, &c., used in the engine and boiler; but no mechanic considers the term "complicated" applicable. If Watt had been commissioned to achieve a similar result, he would have found it necessary, in his day, to multiply the number of engines, merely to obtain the requisite power, and his machinery would have been correctly designated as complicated. Denys Papin, so long ago as 1690, suggested the use of the cylinder and piston, but afterwards employed, or endeavoured to employ, the design of Savery, because of the difficulty in "making these large cylinders," of which he had had experience. The complicated machinery of our engine shops has removed Papin's difficulty, and, as we know, the evolution of machines is still progressing. Humphrey Potter complicated the steam-engine when, to save himself personal trouble, he fixed his strings so that the engine should work the valves automatically, and those who took up Potter's idea made the machine still more complex by their improvements. Watt left us the steam-engine in a far more complicated state than he found it; but, except in a few details, no improvement which has resulted in simplification has been made; for the removal of the condenser, necessary as it is in some cases, reduces the efficiency of the machine as a heat engine. The few details in which simplification has replaced complexity are found in those portions which were of much trouble to Watt, for the reason that he could not find materials or skill to make what he required; but in these instances the complexity is removed to the workshop, in which the steam-engine was the forerunner of improved tools. A steam-engine of the reciprocating type is, however, a complex machine in the sense that a backward and forward motion is first produced in order to attain a rotative one; but it is certain that the engine which will give the rotary motion at once will be more complicated than the well-known type. This point gave rise to an interesting discussion, for Prof. Hele-Shaw had stated in his paper that machines had not only been unsuccessful because proper materials had not been forthcoming, but also because attempts at improvement had been made upon wrong principles. A striking example of that, he said, is furnished by the immense number of unsuccessful rotary engines, which are the outcome of false views of the value of simplicity in a machine. It is proceeding in a wrong direction not only on machinal grounds, but also because it is opposed, on certain general principles, to the best method of employing steam as a working agent; it is, as Reuleaux puts it, "One example of that tendency to aim rather at what we might call the *bravado* in machine construction than at the attainment of practically useful results." Rotary engines have, however, proved successful in a measure, under suitable conditions, and the chairman, Sir F. Bramwell, expressed the opinion that those who had attempted to solve the problem deserved thanks, which brought from Prof. Hele-Shaw the explanation that he was not referring to the efforts to make rotary engines, but to the way in which those efforts had been made through ignorance of the principles applicable. He believes the Tower spherical engine, a marvellous piece of mechanism, is really a success; but it is so because the inventor had struck out a new line. The motor, though externally simple, is really made up of elaborate arrangements, and requires thirty-two figures to completely explain its action and various parts: hence it might be looked upon as a very complicated machine, whereas its complexity is necessary to its efficiency, and renders it perhaps the best of the rotary type. What is true of the steam-engine is true of other machines: evolution leads to complexity, and complexity to greater efficiency. Compare the Martini-Henry with the old Matchlock, and the Gatling with the Maxim gun. The latter carries the cartridge to its place, locks it in, fires it, withdraws the case, and ejects it—all by the force of the recoil; it will, in fact, when once started, go on firing until some portion breaks down, or the supply of cartridges is stopped. But Mr. Maxim properly objects to the term "complicated" being applied to his gun; it might have been made to load and fire itself, without so much of what is called complication; but the arrangements were introduced in order to allow of the magazine being placed under instead of over the gun. This question of complexity is well exemplified in the case of the lathe. To what a complicated machine has the pole-lathe developed, not only in itself, but in its accessories also! What has been evolved from the simple corn-mill of the time of Mithridates (circa 80 B.C.) we see in the "high-grinding" mills, which are almost absolutely necessary to deal with the hard wheats of Hungary and some parts of the United States. Clocks and watches, too, become more complicated as they attain a higher degree of efficiency, and the clumsy printing press of Franklin's time has become the complicated machine which can now be seen in many newspaper offices. With an increased number of parts, there is necessarily an increased liability to derangement; but that is out of all proportion to the increased efficiency of the apparatus, for modern presses now print millions of copies to the hundreds of their older prototypes. We see at one end a roll of paper, at the other we find the printed copies of a newspaper tumbled into a basket, folded ready for the wrapper on which the address is written; but no one who comprehends the machine calls it "complicated." To quote Herbert Spencer's phraseology, "Evolution is a change from an indefinite, incoherent homogeneity, to a definite, coherent heterogeneity, through continuous differentiations and integrations." That phrase will, no doubt, be clearly comprehended by those whose objection to the most efficient railway brake is expressed in the simple, self-satisfying opinion that it is "too complicated." They do not ask whether it is efficient, whether it does the work it is intended to do; but looking only to the number of its parts, they conceive the idea that it is too complicated, and cannot be successfully utilised in practice. A student of Reuleaux's "Kinematics of Machinery"—that is one who comprehends the analysis of machines as a chemist understands the composition of the various substances which come beneath his ken,—would never speak of a machine as being "too complicated," when the very complexity is necessary to attain the efficiency aimed at by the designer, for he would see, as Herbert Spencer sees in connection with progress generally, that "throughout that rearrangement of parts which constitutes evolution, we must nowhere expect to see the change from one position to another effected by one continuous movement in one direction. We shall everywhere find a periodicity of action and reaction, backward and forward motion, of which progress is a differential result." The analysis of machines is the science which really underlies invention: it teaches the simplification of parts and their combination into a complex whole—the "definite coherent heterogeneity" of Herbert Spencer.

## ENGINE-MAKING AT HOME.—III.

### The Cylinder.

EVERYONE who has the slightest acquaintance with the mysteries of engineering design is aware of the fact that very much which passes current for theoretical design is really empiricism—that is, the result of rules deduced roughly from actual practice; and further, that proportions are sometimes given to pieces of mechanism utterly in excess of those demanded by the resisting strength of materials, proportions decided in point of fact by considerations of convenience rather than of actual strength. Water pipes and steam cylinders are cases in point. If we calculate the actual thickness of metal necessary to resist a pressure of 50lb. of steam in a cylinder of 3¼in. bore, we shall find that theoretically a thickness of ·03in. will give us, not only sufficient for strength, but allow us a factor of safety of 10 besides. We know, of course, that it would be impossible to make castings of that thickness for any practical use, so we take an empirical rule suited for moderately sized cylinders:

$$T = \cdot 06\ D + \cdot 2$$

Where T = thickess, D = bore; and we find that this gives us:

$$\cdot 06 \times 3\cdot 25 + \cdot 2 = \cdot 395\text{in.}$$

or a trifle over ⅜in.

Well, we know that this thickness is rather out of proportion to so small a bore;—that if the cylinder were one or two inches bigger, ⅜in. would still be thick enough. But if we lessen the metal very much we run the risk of an unsound or brittle casting, or a casting too hard to bore. So we take the fraction of an inch next below our calculated thickness, that is 5/16in., and feel sure that we have ample thickness in our cylinder, allowing a ⅛in. for reboring at some future time, if necessary.

The area of the steam-ports requires a little attention, and should maintain some definite relation to the piston speed. Steam does not travel, and is not capable of travelling, at an indefinite or infinite rate of speed, as some may imagine; neither is it capable of forcing its way

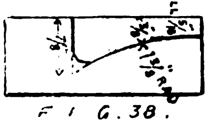

FIG. 38.

through a narrow passage without loss of pressure by friction, any more than water is capable of travelling through narrow pipes without its pressure being reduced thereby. Hence steam ports should be large enough—that is, should bear such a due relation to the piston area, and to its velocity, that the full force of the steam shall be exerted. Thus a common rule is to make the area of the port equal to ·057 area of the piston in a high-pressure engine, presumably of moderate speed, such ratios varying with the speeds in different engines. Taking, therefore, the port area as ·055 of the piston area, with a piston velocity of 300ft. per minute, then—

$$·055 \times 8·2 = ·4510 \text{ area of port.}$$

Let us make the length of the ports equal to half the cylinder diam. = 1⅝in. (quite arbitrary). Then: $\frac{1·625}{·4510} = ·36$ width of port, say ⅜in. The exhaust will be double this, or 1⅝in. by ¾in. Length of stroke is an arbitrary dimension sometimes taken at twice the bore, often less. I have made it a little less than twice—viz., 6¼in. The flange thickness may be $\frac{4}{3}$ of the cylinder thickness:

$$·3125 \times \tfrac{4}{3} = ·4166, \text{ or say } \tfrac{3}{8}\text{in.}$$

Having settled these more important dimensions, let us go to work, draw out our cylinder to full size, and make it.

"Lagging up" is the usual method adopted in making cylinders of moderate dimensions, but in this instance we turn from solid stuff. We shall joint, of course, for the convenience of the moulder, and the joint will run in the direction shown in Fig. 18. To include the "head metal" and prints we shall require two blocks, roughly, 14½in. by 4½in. by 2¼in., and these we shall dowel together with two dowels, fitting tightly into the joint of one half, loosely into the joint of the other. Supposing we have no centre plates, the cylinder being small, we can screw together in the manner shown in Fig. 21, using 2½in. screws, and letting their heads down through a centre-bit hole, so that we can turn the 3in. prints without running foul of them. Rough down, using a turning gouge, and (saving those who are adepts at turning, and prefer the side chisel) scrape the body to a finish with a firmer chisel, to 3⅞in. diam.—the belt standing ⅛in. above this. Fig. 22 gives all the finished dimensions of the *pattern*. 8¼in. over the faces of the flange recesses allows for turning, and 3in. diameter of prints allows ¼in for boring. The 1⅜in. grooves allow for the facings of the flanges and the hollows at their backs. The prints at the ends of this pattern are made as shown—parallel.

Prepare two flanges, which need not be dowelled together in this case; the body being already dowelled—saw out four half-circles 5¾in. diam. by 1⅜in. thick (rough dimensions). Plane one face and the joint edge of each true, and screw upon a true wood face chuck (Fig. 23) first bringing the edge of one half flange against a line drawn across the centre of the plate, and screwing it fast with two wood screws put in from the back, afterwards bringing the edge of the other half-flange to that of the first, and screwing it in like fashion. Bore and turn to dimensions (Fig. 24). The flanges should just be thrust tight by the hand into their grooves, and need not be screwed or bradded.

For the cylinder foot prepare two pieces, $7\frac{7}{8}$in. by $2\frac{1}{4}$in. by 1in. thick, all finished dimensions. Guage two corresponding edges to $\frac{3}{4}$in., and placing them together, mark a portion of a $3\frac{7}{8}$in. circle on the ends, cutting these gauge lines. Work through this curve with a paring gouge or round plane, and cut out portions besides to fit over the belt of the cylinder, and over its flanges, the ends of the curves being also rounded a little to fit the hollows of the flanges (Fig. 25). At this stage take the cylinder body apart, and laying the half containing the dowel *holes* on a true board, check one half of the foot, with a set square (Fig. 26), and if not at right angles, or if, as is most probable, it does not bed properly, chalk the cylinder and ease the foot where required. When fitted, screw in place, put the other half of the cylinder in position and get its half-foot also to correspond with the first. Then unscrew, rebate, and hollow the back (Fig. 18, *a*, *a*), and replace finally. The joggle on the face (Fig. 18, *b*) will not appear till the casting is planed, when the feet, being planed back on each side, will leave it standing above.

Small brackets (Fig. 18, 19, *c*, *c*) will be fitted between feet and flange, $\frac{5}{16}$in. thick—$\frac{3}{16}$in. because they shall stand back $\frac{1}{16}$in. from the faces of the flanges when the latter are turned. Fit in with gouge and chisel, glue and brad. In glueing portions of patterns together, be sparing of glue, for if you get it in superfluous amount working out of the joints in the sand. the mould will become torn and damaged thereby. A very small quantity of glue, moreover, will suffice to make a strong joint if the latter is close fitting.

We come now to the provision for steam ways. The first piece we shall require will be a block $7\frac{1}{4}$in. by $2\frac{1}{4}$in. by $1\frac{1}{8}$in. (finished dimensions) to form the metal round the passages (Figs. 18 and 19, *d*, *d*, *d*). Strike the curve of the cylinder on each end of this, and work until it fits round the body between the flanges, taking care not to reduce the thickness below the $1\frac{1}{8}$in. on the edges. Prepare a piece for the steam-chest face $6\frac{1}{8}$in. by $4\frac{1}{4}$in. by $1\frac{1}{8}$in. (finished), to include the hollow on the back, and dowel it centrally upon the passage block on the opposite face to that just curved, being particularly careful to keep the edges of each parallel up and down (Fig. 27). At this stage it will be well to fasten the passage block in position to be sure that our height is correct, and that it is both parallel with the joint and central with the cylinder body. To do this, lay the joint of the cylinder on a true board, and placing the saddle piece with its flange on the back, try with set squares held against the flanges (Fig. 28), until we get equal dimensions from the latter to the passage body, viz.: $1\frac{9}{16}$in. Then lay a straight-edge across the face of the flange, and whichever way it is turned up or down, or across, we should measure alike, $3\frac{3}{8}$in., from face of flange to joint of pattern. If we find that it is out of parallel, a shaving or two must be taken off the *joint* of the passage block where necessary. When all is correct, set the block by running a couple of screws through it into the body.

Beyond the ends of the flange (Fig. 19, 27) the passage block follows the curve of the passage core with a radius struck from the centre of the cylinder—viz., $2\frac{3}{8}$in. Work this with a chisel, and let it merge into the flange with $\frac{1}{4}$in. hollow. Then the flange edges standing out beyond the block at the sides, have to be gauged to $\frac{1}{2}$in. thick, and these also will merge into the block with $\frac{1}{4}$in. hollows.

Lastly, upon the flange add the valve facing, $4\frac{1}{8}$in. by $2\frac{1}{2}$in. by $\frac{1}{8}$in., and upon this again brad three prints for the passages (Fig. 19). The middle print will measure $1\frac{5}{8}$in by $\frac{13}{16}$, the two passage prints $1\frac{3}{8}$in. by $\frac{9}{16}$in., and all alike will be, say, $\frac{3}{8}$in thick. The exhaust print will be fastened on exactly in the middle of the facing, and the two port prints $\frac{3}{8}$in. away on each side. These dimensions, of course, are measured on those faces of the prints which go against the flange, and their ends and sides both taper away from those dimensions—say, $\frac{1}{32}$in. Note that the ports are slightly rounded in the corners. This is to prevent the face of the valve from being cut and grooved. The corners of the prints will therefore be rounded similarly. The exhaust branch is turned to dimensions (Fig. 29), and its flange is turned without a joint, and slips over the print just easily (Fig. 30). Then the branch is cut to fit against the steam-chest flange (Fig. 31), until its centre measures $2\frac{3}{8}$in. from the centre of the cylinder (Fig. 18), and a couple of small hollows are glued in to fill up the angular space (Fig. 32). We do not screw this branch permanently in place, for then the moulder would have to lift away the sand above it with a "drawback," which is neither necessary nor desirable in this instance. So we make a sliding dovetail in hard wood, screw it on the end of the branch, and let it slide in a corresponding groove cut in the side of the passage block (Fig. 33.) This cannot shift during the ramming up, and when the cylinder body is lifted out, the branch is afterwards withdrawn into the space left by the body, leaving the flange behind. A piece of flat loam cake, which the moulder has taken the precaution to lay against the face of the branch flange, is now removed, and into its space the flange is drawn, the cake being replaced after the mould is finished. The above is one of the few instances where a sliding dovetail is preferable to "wires" in loose pieces.

Prepare two blocks to Fig. 34 for pump facings, and fasten them upon cylinder in positions shown in Fig. 20.

The passage core box need not be built up as in the case of a large cylinder, but can be made from two blocks of solid wood dowelled together and worked according to dimensions in Fig. 35. The curve section *a* is worked to a $1\frac{13}{16}$in. radius with concave templet A (Fig. 36); that marked *b* is worked to a $2\frac{5}{16}$in. radius, with convex templet B. The thin strips $1\frac{3}{8}$ by $\frac{1}{8}$ by $\frac{1}{32}$ give the chipping allowance on the edges of the ports. The curved portion, C, fits the cylinder core, and the portion, D, without the dotted line, drops into the print. The exhaust core box will be made to the dimensions of Fig. 37, which represents one half laid open in the joint (Figs. 38, 39, 40), showing the sections across the centre line, and at the two ends.

Too much pains cannot be taken with these core boxes, since a small amount of error where we have but $\frac{5}{16}$in. of metal may readily reduce that metal below its proper thickness, and then the probabilities are that we shall get the casting spongy in those places, and that the air holes will make an opening from one passage into another. Such casualties do sometimes occur even in larger cylinders than ours. Therefore, use templets, and be sure that lengths of passages and curves of same are correct. Hollows need not be put in the boxes to match the rounding of the prints—the moulder seeing the prints rounded will rub the cores to match. No provision is wanted for the central core.

I have said nothing about taper. In so small a pattern we can ignore that. Yet even in this a pattern-maker would put taper by mere force of habit, taking just one extra shaving off the lower portions of the work, or bearing harder there when glass-papering. At any rate, the difference, though imperceptible with the rule, can be detected by calipers, and is sufficient to allow ease of delivery from the sand.

## TELEGRAPHING TO AND FROM TRAINS IN MOTION.

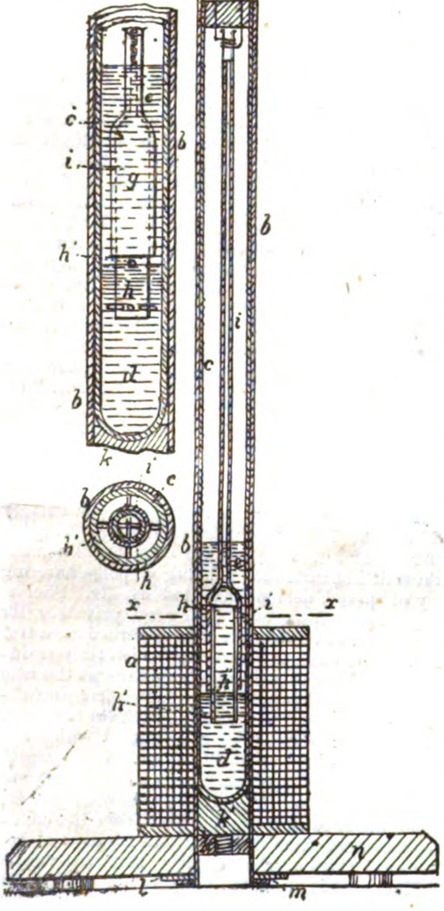
WHAT promises to become an historical event in railway signalling was witnessed last month on the New York, New Haven, and Hartford Railroad, when the system of communicating between moving trains and the stations along their route, invented by Mr. Lucius J. Phelps, was successfully experimented with. It will be remembered that several inventors have already turned their attention to this subject, and there are not a few more or less feasible schemes which, judging by appearances, will be heard of no more now that Mr. Phelps has discovered a means of utilising an induced current instead of having an "electric rail" to convey the current. His conductor consists of a No. 12 American gauge insulated wire, which is placed in a 3-8in. groove made in string-pieces 2in. square in section, and covered up with a lid 3-8in. thick. The string-pieces are mounted on blocks nailed to the sleepers, midway between the metals, so as to bring the wooden trough containing the conductor to the same level as the rails. At crossings, the wire is inclosed in stout rubber tube and carried under the crossing rails, —the rubber tube entering the wooden box or trough at both ends for a short distance to guard against damp and injury. At level crossings, where ordinary wheeled vehicles pass over the metals, the conductor is carried in strong wrought iron tubing, which is securely fastened to the sleepers. In order that the experiments might thoroughly test the merits of the invention, a portion of line was chosen on which there are two drawbridges for crossing rivers, 26 switch or other rail crossings, and 47 places where the public highway has to be provided for. The circuit with station instruments is completed in the usual way by means of ordinary telegraph wires. In cases where the induction current is used, it is advisable to have the wires parallel for as long a distance as possible, and comparatively close to one another. For that reason the new telegraph car carries a 2in. iron pipe suspended 7in. above the level of the rails. In this pipe is a rubber tube $1\frac{1}{4}$in. in diameter, containing 90 convolutions of No. 14 (A.G.) copper wire, single-braided and paraffined, so connected as to form a continuous circuit about a mile and a half long, and presenting about three-quarters of a mile of wire parallel to the primary line wire between the rials. The return portion of the coil is taken back through a rubber pipe which runs up to the roof of the car, with the object of removing it as far as possible from the lower branch. The terminals of the car, or secondary, circuit are taken to a key for transmitting, thence through the back contact to a delicate polarised relay devised by Mr. Phelps, which acts as the receiving instrument through an ordinary sounder placed on a sounding-box above the glass shade covering the relay. The car is fitted with a battery of five cells, one of which is used to work the local sounder, the other four to transmit messages. The current passes from the front contact of the Morse key through the coil, and through a "buzzer" or rapid current breaker, which causes a humming noise resembling that of the bee. This "buzzing" is, of course, broken up into Morse characters by the key, and they are received at the station in a telephone. Messages are sent from the station to the train by a battery of about 12 cells, capable of giving a current of about $1\frac{1}{2}$ ampère over the line, the transmitting instrument being a pole-changing key of special design invented by Mr. Phelps. Experiments have been going on privately for some time, but on what was regarded as a test trial before experts, words were distinctly transmitted while the train was travelling at the rate of 25 miles an hour, a heavy snowstorm prevailing all the time. Messages have, however, been clearly and unerringly transmitted while the train was travelling at 40 miles. It is worth noting that on one occasion, when, owing to some repairs to a trestle bridge, the line wire was for some distance actually four feet from the coil, a message sent from that spot was received at the terminal station, the signals being perfectly distinct. It is much too early to assert that the system will be available under all conditions; but it has been proved and tested: the remainder can be left to the developments of the future.

## MILLER'S NEW ELECTRIC METER.

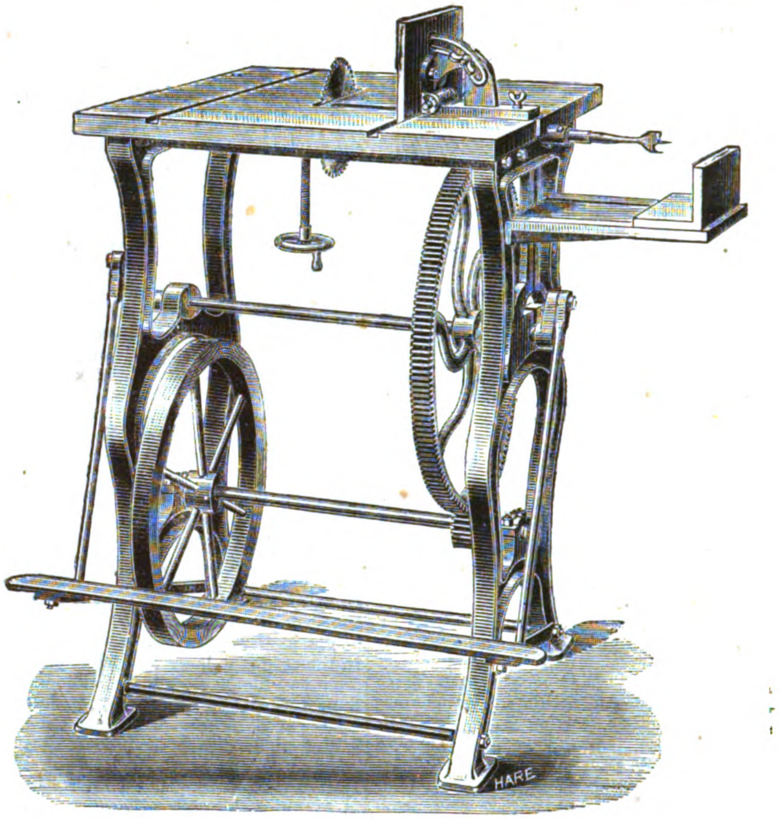
SOME improvements in electric meters have been recently patented by Mr. L. B. Miller, of Bolan-street, Battersea, S.W., which are applicable for instruments intended to measure ampères, volts, or volt-ampères. At the lower end of a vertical brass tube a coil or coils of insulated wire is wound, having the ends connected to suitable terminal screws fixed in a circular wooden base. Inside the brass tube (which has its sides cut away for the greater part of its length) there is a closely-fitting glass tube closed at its lower end by fusion. At the bottom of the glass tube, where it is within the wire solenoid, there is a small quantity of mercury, and over this some alcohol coloured red. Floating in the mercury and alcohol is the plunger of the instrument, the construction of which is as follows:—A small piece of sheet charcoal iron, thin and extremely soft, is bent into a tube. This forms the core of the solenoid. A piece of glass tube similar to a thermometer tube, but not so thick, is fused to the top of a short length of glass tube of such an internal diameter that the iron core will just fit into it and project a short distance underneath. Into the bottom of the iron core are fixed four small guides to keep the plunger central. The core and the glass surrounding form "the plunger," and the prolongation of the glass upwards the "indicating tube." The level at which it will float is found, and there a small hole is made through the iron or through both iron and glass. In order to increase the buoyancy of the plunger the patentee sometimes surrounds the iron core below the glass with a small ring of ebonite. The top of the outer glass tube is closed, either by fusion or with an indiarubber stopper, having previously formed a small guide of twisted wire to keep the top of the indicating tube at the centre of the outer glass tube. The spirit cannot, therefore, evaporate, and the instrument may be easily transported, and even inverted, without being damaged or disarranged.

The action is as follows:—When the current passes round the solenoid the iron core of the plunger is attracted towards the centre of the solenoid. Directly it commences to move downwards the small hole or valve at the junction line between the spirit and the mercury is covered up by the latter, and the spirit inside the plunger, having no exit, is forced up the bore of the indicating tube for a distance depending on the power of the current to drag down the iron and glass against the buoyancy of the mercury and spirit, a small movement of the plunger necessarily causing a large rise of the spirit in the fine tube. The patentee has found by experiment that if the core is about two-thirds of its length within the solenoid, and moves only through a small distance, the rise of the spirit as shown on a conveniently placed scale is proportional to the current strength when the glass and core are quite cylindrical and the iron very soft and thin. If these conditions are not fulfilled the readings will not be proportional, but must each be marked separately on the instrument. If, however, some other non-magnetic material, such as ebonite, is used instead of the glass, it may be turned till its shape is made such that the distance it will be pulled down is strictly proportional to the current strength. Therefore, by constructing a core in the manner described, that floats in mercury or, preferably, in mercury and a lighter fluid that will act as a lubricant, a vertical movement that is strictly proportional to current strength may always be obtained, and this movement may be utilised in various forms of electrical measuring instruments.

FIG. 2. FIG. 1.



When the instrument is required to measure ampères, the solenoid is covered with a few turns of thick wire placed in the main circuit; when volts are to be measured, thin wire offering a high resistance is used, and placed as a shunt to the main circuit; and when volt-ampères are to be measured, the solenoid is either wound with both main and shunt wires, or the selenoid with the main wire and the core with the shunt wire, protecting the latter from the mercury by guttapercha, and making suitable flexible connections. Fig. 1 is a central vertical section of part of the instrument, and Fig. 2 shows details drawn to an enlarged scale, the lower portion being section on line *x*—*x*, Fig. 1. Referring to the drawings, *a* is the solenoid, *b* the protecting brass tube, *c* the outer glass tube, *d* the mercury, *e* the alcohol, *h* the iron core, $h^1$ the iron guides in the core *h*× the small hole in the core at the junction line between the mercury and the spirit, *i* the glass portion of the plunger, *j* the indicating tube, *k* a screw for regulating the position of the iron core, $k^1$ a piece of ebonite interposed between the screw *k* and the bottom of the tube, *l* a washer interposed between the nut *m* and the base of the instrument *n*.



## BRITANNIA COMPANY'S FOOT-POWER CIRCULAR SAW.

AT the Architectural and Building Trades Exhibition, recently held under the auspices of the Society of Architects at the Floral Hall, Covent-garden, the Britannia Company exhibited their newly-patented circular saw, which is shown in the annexed illustration. This machine is, in reality, a combination tool especially adapted for pattern makers, cabinet makers, joiners, picture frame makers, and all workers in wood. The gear gives a speed on the saw spindle of 1,500 revolutions per minute with ordinary treading, and the machine runs so easily that the saw will actually cut 3ft. 8in. of 1in. mahogany after the foot is removed from the treadle, and with a saw of the requisite size, hard wood up to 4in. thick can be cut. Grooving is done by the use of a thick saw set on the skew with washers, and fret-cutting can be done by removing a portion of the table, and attaching a cam to the spindle in place of the circular saw, the fret-saw being suspended from an arm overhead. Curves can be cut in pine or mahogany 4in. thick. Dowelling and drilling can be accomplished by the appliances shown on the right-hand side, the machine being powerful enough to bore up to 2in. in diameter. With suitable saws common picture-frame mouldings can be mitred up without any planing, and by the aid of the adjustable guide all sorts of saw-cuts can be made. The machine will be on view at the Building Trades Exhibition, and will be publicly tested; but meantime, having examined it, we can say that it is an economical and very useful tool.

## HARDENED AND TEMPERED GLASS.

IN Vol XXII. page 599, we gave an account of the experiments made by Mr. F. Siemens, of Dresden, in the hardening and tempering of glass, a subject which, just at the time had attracted much attention in consequence of the introduction of the De la Bastie toughened glass. A short experience with the latter sufficed to show that by dipping the hot glass in a bath of oil a state of tension was set up amongst the molecules, and the so-called "toughening" was frequently found to be only a deceptive hardening. Since that time Mr. Siemens has been steadily pursuing his investigations, and has now achieved so much success that he recently read a paper before the Applied Chemistry Section of the Society of Arts, from which we make the following extracts:—

Having satisfied himself by a series of experiments of the true cause of the spontaneous fracture of glass, Mr. Siemens invented processes of manufacture by means of which glass may be thoroughly toughened, or, as he prefers to call it, hardened. The principle upon which the processes depend consists in cooling the glass, not in proportion to its surface, but to its volume or capacity for heat. The method employed will be readily understood by considering a sheet of uniform thickness, which, after having been heated uniformly to a sufficient degree, must be cooled on the surfaces of its two parallel sides only, leaving the edges uncooled. This is done by placing the heated sheet of glass between two cold slabs of suitable material, prepared in a peculiar manner. Uniform cooling of the whole sheet is thus secured, no matter what its shape, because the edges are not subject to the cooling influence caused by the surfaces between which the glass is placed. The plan adopted for various articles varies with their shapes; but it is on the principle of uniform heating and cooling that the author's processes of manufacturing hard glass are based.

Of these, the two principal are known as press-hardening and casting; but, besides these, there is a third, theoretically less perfect than the others, viz., semi-hardening or hard-tempering; this, though less important, may be advantageously employed where presses would be unsuitable, and casting impossible or difficult, as in the case of bottles, lamp chimneys, &c.

Press-hardened glass has now been made, with constantly-increasing success, for six years. The articles are mainly of plate and sheet glass, either flat or bent into a variety of shapes. Besides plain work, decorated sheets, such as signboards with enamelled inscriptions, figures, and other ornaments, form an important part of the goods produced; the process, as already stated, is, therefore, one of manufacture (the goods receiving through it their definite shape and decoration), and not simply one of hardening or toughening. The glass is so hard that the diamond will not touch it, and it cannot, therefore, be cut or bent after manufacture; it may however be polished, etched, and slightly ground; its strength is at least eight times that of ordinary glass.

The process of manufacture is as follows:—The glass is first cut in the ordinary way to the requisite shape and dimensions, and is then exposed to the radiant heat of a peculiarly-constructed furnace until quite soft; as soon as it has attained the necessary temperature, it is placed between cold metal plates, to be cooled down with a rapidity which varies with the thickness of the glass, but is in any case very great. The heating and cooling of sheet glass of ordinary thickness last altogether a minute and a half, a minute being the length of the heating, and half a minute that of the cooling operation. It is a remarkable circumstance that glass may be thus heated and cooled in so short a space of time without either cracking or breaking; this is altogether due in the case of the operation of heating to the uniform temperature of the furnace, and to the heat being produced entirely by radiation; should these conditions not be fulfilled, the glass would break to a certainty. As regards the success of the cooling operation, this depends upon the uniform temperature of the glass before it is cooled, and upon that of the metal plates between which it is placed whilst being cooled. This uniformity of temperature, and the total absence of draught, which would cause irregular cooling, are the conditions under which the whole operation can be carried on with assured success.

The surface of the metal plates, or moulds used for the presses, may be so prepared as to produce more or less cooling effect on the glass as required. If the glass is to be hardened to a very high degree, the metallic surfaces must be of very high heat-conducting power, such as copper, and must be left quite bare; the glass must also be raised to a very high temperature, as it would otherwise crack during cooling. If it is proposed to harden the glass to a lower degree, surfaces of iron are used, this metal not being so good a conductor of heat as copper, whilst the temperature of the glass is also kept lower. By covering the surfaces of the iron presses with wire gauze, their cooling effect may be reduced to any required extent, so that a certain amount of hardening may be produced without rendering it necessary to heat the glass to such a temperature as to make it difficult to handle, or to cause it to stick to the furnace bed. If a still lower degree of hardening is proposed, the faces of the presses may be covered with asbestos paper, or even clay slabs may be employed.

Semi-hardened glass is made in the same large radiation furnaces as press-hardened, by means of the hard-tempering process, of which the following is a description:—Finished articles, which are of a shape to which presses cannot be easily applied, such as bottles, are heated up to a temperature short of softening; each one is then placed in a casing of sheet iron, which is so arranged that the heated article shall not touch the inner sides of the casing. In order to effect this, the casing is provided with internal projecting ribs, which retain the glass article in position, touching it only at very few points. The casing with the heated article of glass within it is allowed to cool in the open air. Whenever it is a difficult matter to handle the heated glass, instead of placing it hot into the casing, the casing with the glass inside it is inserted in the heating furnace for the requisite time, and then allowed to cool as before described.

The third and last process to be described, which Mr. Siemens considers the most valuable of the three, is a peculiar mode of casting hard glass. This has not yet been introduced on a manufacturing scale, but the experimental castings produced have turned out to be quite satisfactory in every way. They consist of floor plates, grindstones, pulleys, tramway sleepers, and various ornamental work.

Hard cast glass is manufactured in the following manner. Glass, melted in a tank furnace, is tapped into moulds, as with iron castings. The process thus far resembles that carried on in an iron foundry, but differs from it, inasmuch as a special material is used in place of sand, and that the mould and the glass inside it are heated and cooled together. The material or mixture to be used in place of sand must be selected so as to have, as nearly as possible, the same conductivity and capacity for heat as glass; in such a case, the glass and mould forming, as it were, one homogeneous body, the glass will cool without cracking, even if the cooling process is comparatively quick, which is quite necessary if hard glass is to be produced. Glass cast in this way may have almost any variety of form and inequality of thickness. In the last respect this process differs entirely from those previously described, in which only glass of uniform thickness can be dealt with. If care be taken that the surface of the glass does not approach the outer casing of the mould, it does not much matter how the cooling is effected. The great point is that the mould and glass should be brought to a uniformly high temperature, which should be rather above that at which press-hardened glass is made. When fully heated, the mould is taken from the furnace and allowed to cool in the open air, which generally acts quickly enough to produce a good hardening effect upon the glass within. When cold, the mould is opened, and the glass removed.

It will be readily understood, from the descriptions given, that the three processes differ so materially from one another, that hardly any resemblance remains to show that they are merely different ways of treating differently-shaped articles, in carrying out the principle of keeping the whole body of the glass at a uniform temperature during the operations of heating and cooling.

The De la Bastie process, as well as the ordinary tempering processes employed, fail in not being founded on the principle set forth; glass toughened by the De la Bastie process being cooled in a fluid bath, and ordinary glass in kilns, the cooling action is most active on the portions offering the largest surfaces to the cooling influence, and hence in the one case there is a strong tension or strain in the molecules, which causes them to break up spontaneously; and in the other case, to counteract that tendency, it is necessary that the glass should be cooled very slowly.

In the discussion which followed the reading of the paper Mr. E. A. Cowper said thanks were due to Mr. Siemens for bringing forward this new manufacture in a practical form. Several of the drinking bottles he had seen for some years past, and they were very much liked because they were clean; tea could be put in them one day and beer another. The question of cutting with a diamond was a very curious one. You could scratch the surface of some of these sheets, but you could not cut it; it would not split through as common glass did. Probably that was due to common glass being in a state of tension, which, when relieved by a scratch, caused the glass to fly right through; so that even plate-glass ¼in. thick would succumb to the slightest scratch of a diamond $\frac{1}{100}$in. deep. With this glass you could not do that. The castings would be an important new manufacture. The tempering was not so thoroughly carried out in this case as in the hardening of glass in other forms, but it was sufficiently hard to serve as sleepers for tramways and railway chairs for electric railways. He thought also architects would welcome this as a means of obtaining articles of various tints, whereas they at present had to search for different stones. By this process they could obtain them, to any extent, in various tints, and in any form, by casting.

Mr. Ludwig Mond said: As a chemist, he might remark that, when the question of glass turned up, it was found to be now practically the same substance chemically that it was at the time of the Phœnicians. He certainly thought it would repay the chemist to attack the question from the chemical point of view, and see what could be done, not by mechanical processes—by heating and cooling—but by attempting to produce new chemical compounds which should possess the qualities desired.

Mr. Siemens remarked that the glass tuning-fork, which was found to be very resonant, could not be produced at all in ordinary glass in a mould, as it would be sure to crack. It could only be produced by pouring it into a mould formed of a material having the same heat-conducting power.

In answer to some remarks, Mr. Siemens said his process and that of De la Bastie could scarcely be compared, because the latter was merely a toughtening process, whilst his was one of manufacture, by means of which he shaped and hardened the glass in a single operation, either by means of presses, or casting into moulds, and in a new manner. The De la Bastie process was only an additional operation, applied after the article was finished, to toughen it; but even for that purpose it was wrong, inasmuch as the cooling influence acted in proportion to the surface, whereas it ought to act in proportion to the bulk of the glass. Those parts which exposed much surface to the cooling influence, cooled more quickly than those of less surface, and, consequently, there would be unequal cooling, which should be avoided.

The chairman, Prof. Dewar, remarked that specimens of De la Bastie's glass, examined by the polariscope, exhibited the existence of enormous strains, and he should like to know whether the Siemens glass showed anything of the kind, to which Mr. Siemens replied that it did show something of that nature, but not much.

## THE EXPERIMENTS ON FRICTION.

COMMENTING on the recent experiments in connection with friction, the *Engineer* says:—If it can be shown that bearings do not give any trouble now, and use very small quantities of oil, it may be asked, what does it matter whether the coefficient of friction is 0·01 or 0·001? It is a noteworthy fact that, although the Institution of Mechanical Engineers set these experiments on foot, its members seem to be quite content to place the results on record in their *Transactions*, and do nothing more. Surely they are worth a better and fuller discussion than they have yet received. The most troublesome class of bearings with which the engineer has to do are those of marine engines. It seems to be quite impossible to work them cool without employing quantities of cold water. The crack racers of the Atlantic—such, for example, as the *Arizona* or the *Oregon*—have spray pipes fitted over the crank pits; and from these a deluge of water is distributed during the whole run. The water is never shut off, save for a moment when a man feels the bearings to ascertain if they are running cool. There is besides a 2in. hose always ready for action. Why should all this be necessary? It may be said that the great heat of the engine-room tends to make the bearings hot. But the crank shaft stage in such ships as we are speaking of is not hot at all. The cylinders are away far up overhead. The boiler-rooms are shut off by the bulkhead. We have felt chilly in the crank-room, as it may be called, of one of these great ships. Why is it, again, that the bearings of a locomotive hardly ever heat? It may be taken as proved that if a locomotive is properly designed and properly worked, there will be no trouble from hot bearings; yet the loads per square inch of surface are very heavy indeed. Take, for example, a big end brass; the bearing will be 4in. long and 8in. in diameter, the pressure on it with a 17in. cylinder and 120lb. pressure will be 27,240lb.; the bearing surface will be—allowing one-third of the total surface to take the strain—33in., let us say. Thus the load per square inch will be 825lb., which is much more than is usually deemed safe. In small stationary engines, on the other hand, we constantly find that the bearings give a great deal of trouble. Why is this? Have the experiments of Mr. Towers thrown any light on the subject, or helped us to the reason why? We think not, or rather, we should say, that engineers as a body think not, for we still have hot bearings, Mr. Towers to the contrary notwithstanding. Our own explanation of hot bearings is that they are in nearly all cases due to some bending or pinching action. Heating can be set up by a very minute cause, and once it is started, it will go on. In one out of many cases, in fact, which have come under our knowledge, where a crank pin heated persistently, the evil was due entirely to the circumstance that the crankshaft was too weak, and bent and whipped under the strain. It will constantly be found that crankshafts will run quite cool, unless the bearings are so far screwed down that the crankshaft has very little play. In other words, absence of "knock" and heating go together. The received explanation of this is that when the brasses are a loose fit the oil gets between the surfaces. This may be a partial explanation, but not a complete one, because it leaves the fact unexplained that bearings will not invariably heat because they are screwed up. When hot bearings are normal to an engine, we believe—we had almost said we know—that something is out of square; there is want of truth and accuracy. A slack brass is simply a crude expedient for obviating this difficulty. It permits the rubbing surfaces to play about and adjust themselves to each other. No properly-designed, properly-lubricated bearing wants to run hot. If it heats, it is driven to it, so to speak, against its principles. One reason why a locomotive runs cool is that provision is made for a great deal of self-adjustment. This is necessary in a machine which runs over a comparatively uneven and crooked surface. There is elasticity, and this serves a useful purpose. We too often find, however, in steam machinery that a partial and very mischievous elasticity is introduced by the employment of parts too small and light for their work. James Watt and the early engineers could not have got on at all if they had not made special provision for want of accuracy in workmanship. Thus the connecting rod was always connected to the beam end by one universal joint, and very often there was another at the crank shaft end of the rod. The piston-rod and parallel motion, and the beam and the air-pump rod, were all mutually accommodating. The result was that these old engines are running, many of them, to this day.

Returning once more to Mr. Towers's experiments, we ask for information as to whether anyone is acting on the discoveries—for they are nothing else—and if so, with what results? We confess that we have failed to discover anyone who is the better in any respect for them. This ought not to be the case. Everyone says that they are of great value; is it wrong to ask of what value? Are they worth something to the community in a pecuniary sense? if not, why not? Nothing is more to be deplored, we think, in engineering than that the intelligent, costly, and successful labours of a member of the profession should be thrown away.

It reminds us of the work done by Government committees, who take evidence and pursue investigations, extending over months, it may be years. Finally they report. But nothing comes of the report.

## THE CHEMICAL NATURE OF COTTON.*

CELLULAR filaments, turgid with nutrient and astringent juices, springing from the nearly ripened seed and intertwining in a seeming tangled mass; soon lengthening and becoming hard and ligneous; then the remnant of the sap dries up within them, and they shrivel to flattened, twisted, sear (and sometimes yellow), lifeless—*cotton fibres.* The chemistry of cotton began with the art of dyeing, in India; the ancient Egyptians were skilled in dyeing *al-quton*; they were not required to reconcile the cotton with coal-tar colours. A knowledge of the physical structure and chemical constitution of the cotton fibre does not explain its indifference to most dyes, nor can its affinity for a certain few colouring matters be understood, because it does not appear to form chemical concombinations with these: they can be readily removed, leaving the fibre unchanged. The ripe fruit of the cotton-plant (Gossypium, from the Arabic *goz*, a soft substance) is a large capsule containing a mass of the filaments which envelop and adhere to the seeds. The fibres from different species of the plant vary in length, thickness, flexibility, tensile strength, and colour; the diameters are from $\frac{1}{800}$ to $\frac{1}{2500}$th of an inch, and the lengths from 0·77 to 1·80in.; the mean diameter of Sea Island cotton fibres is $\frac{1}{1362}$nd of an inch, and the average length 1·60 inches; some cottons are highly coloured, like the so-called *Nankin*, and the whitest contains some natural colouring matter, which is of the same character in all cottons, and consists of two bodies, one freely soluble in alcohol, the other not. Clean cotton is nearly pure *cellulose*; the associated substances are in varying and exceedingly small proportion, and may be removed by means of hot alkalies, dilute acids, and ether; the bodies obtained by this treatment are found to consist of waxy, albuminoid, and colouring matters; ulmic, pectic, and fatty acids; calcium and sodium sulphates; and ferric, silicic, and aluminium oxides, with traces of potash and magnesium phosphate. The ulmic acid, perhaps, results from the action of the chemical agents on woody tissue (not cellulose), and in like manner the pectic acid may be formed from insoluble pectose.

Cellulose is the principal material in the structure of plants; the natural process of its formation and its relations to allied bodies constitute one of the most interesting studies in science. The formula of pure cellulose is $C_6H_{10}O_5$, or $C_{18}H_{30}O_{15}$; therefore it is composed of carbon and the elements of water, or, empirically, it may be said to consist of carbon and water. It is isomeric with dextrine and starch, and differs from natural gum and the sugars (glucoses and saccharoses) only in the relative quantities of water elements. By simple chemical means cellulose may be changed to gum, to starch, and to sugar; by natural process the plant converts starch, gum, and sugar one into the other or into cellulose, according to the requirements of its different parts. Are these changes produced simply by alteration of molecular structure? "The theory of atomicity . . . . interprets the most complicated cases of isomerism"—with exceptions. We know that the vital principle of the plant directs the formation of tubes of cellulose, as conduits of the sweet sap from which they are produced; that the same saccharine juice deposits gum and, in the seed, starch, and that this starch, in the new growth, by the stimulation of diastase, changes itself to the forms of gum, and sugar, and cellulose, exhibiting in matter phenomena that suggest the convertibility of the different forms of energy; but we cannot explain these transmutations, nor do we understand why the presence of a small quantity of acid should convert a handful of old rags into an equal weight of sugar.

How do plants produce these bodies, composed of carbon with hydrogen and oxygen in the same relative proportions as in water? The hydrogen can only come from water: the plant obtains that through its roots, and as it does not receive oxygen from the air, water may also furnish that element, while, under the influence of light, the leaves absorb carbon dioxide, the source of the carbon. The plant now has water and carbon from which to form its starch, gum, sugar, and cellulose. By resolution of the carbon dioxide, and directly combining carbon and water? The process of eremacausis, or natural decay of woody fibre, would indicate this. It consists essentially in evolution of water and oxidation of carbon, with reproduction of carbon dioxide. But another consideration forbids this view. Not only do plants form bodies composed of carbon, hydrogen, and oxygen, but they also produce waxes, caoutchouc, essential oils, and resins, consisting of carbon and hydrogen, and containing little or no oxygen; therefore, the plant must have the power to decompose water, and appropriate only the hydrogen. Hence, it seems possible that the cellulose and allied bodies are produced by the combination of hydrogen from water with carbon dioxide, the oxygen of the water being emitted.

Although cellulose is so readily convertible to gum, starch, and sugar, it resists chemical action in the stomach, and is as innutritious as clay. It is scarcely attacked by dilute acids and alkalies, but strong sulphuric acid and zinc chloride change its physical character; "parchment paper" and "vulcanised fibre" are respectively produced by these agents. A solvent of cellulose is obtainable by dissolving cupric carbonate (formed by precipitation from the sulphate) in ammonia; it easily dissolves cotton, particularly so-called "absorbent cotton," and acids precipitate the cellulose in flocculent form.

Remarkable changes are effected in the nature of the cellulose or cotton by the action of concentrated nitric or mixed nitric and sulphuric acids; hydrogen is removed, and the radical nitryl ($NO_2$) substituted, with formation of pyroxylins or varieties of nitro-cellulose. True "gun-cotton" or trinitrocellulose, $C_6H_7(NO_2)_3O_5$, is made with the more concentrated acids, while acids containing more water yield less highly nitrated or "soluble" pyroxylins, which are used in the manufacture of collodion, celluloid, zylonite, &c. To determine whether the alteration of structure and chemical nature of the cotton fibre had developed affinity for aniline colours, a few tests were made with pyroxylins; ordinary rosaniline dyes were used, and the trisulphoacid of rosaniline (Holliday's acid magenta); the trinitrocellulose rejected the dyes, while the partially nitrated cotton retained the colours after washing with soap and water. A way to make cotton receptive of colours, without the use of mordants, and means of rendering it less combustible, of removing the harshness of inferior grades, and of bleaching it cheaply without injury to the fibre, are desiderata that have engaged the attention of many chemists. An increased affinity for dyes may be imparted by preparatory treatment with hot dilute alkali, which removes most of the waxy and fatty matters, and notably alters the shape and dimensions of the fibre; it contracts in length, and approximates to the form of a simple round tube, with a clear hollow from end to end.

Cotton may be distinguished from other vegetable fibres, such as flax and hemp, with the microscope, and from wool and silk by simple chemical tests—for example, hot dilute alkaline solution does not affect cotton, but quickly dissolves the animal products; a solution of the trinitrophenol picric acid dyes wool and silk a permanent yellow, but washes away from cotton, leaving it white; or instead of the dye, dilute nitric acid may be used, which produces picric acid from the animal substance; a hot solution of mercuric nitrate imparts a red colour to wool and silk, but leaves the cotton unchanged; by boiling cotton with dilute hydrochloric acid it becomes rotten, while wool and silk are not thereby changed; a solution of lead monoxide in dilute alkali blackens wool, but not cotton; a solution of zinc chloride dissolves away silk from cellulose, &c.

## DODGES FOR AMATEUR PHOTOGRAPHERS.*

ANYONE owning a fret saw can make vignetting boards with ease. Mark out the shape of vignette required on a piece of half-inch soft pine. Set the saw-table on a bevel and cut out. Cut about three, taking care to mark each one from the smallest end of the hole of the board last cut. Tack together with 1¼in. brads, and cover the top (the smallest end) with tissue paper.

I recently required a dish to silver some paper on, and none could be obtained near where I live. I made a dish in the following manner: First cut out out a block of wood the exact size and thickness of dish required. Then take a sheet of cartridge paper, paste it with flour paste, and rub in the paste well letting the paper be thoroughly soaked with it. Then place the paper evenly on the wooden block, turn down the edges smoothly, and double the corners back, rubbing them down well. Be very particular with the first sheet, because if you get that smooth, the rest is easy. Follow with another sheet of cartridge paper, turning the surplus of slack paper at the corners the opposite direction to the last. Follow with five or six sheets of old newspapers in the same way, and cap with another sheet of cartridge. Put the block with the paper on it into an oven and bake till dry. Then take out the block and trim the edges. Paint the outside of the paper dish with varnish. Pour some varnish inside the dish and let it soak in, and then pour off the surplus. Bake in the oven again. After the varnish is hard and dry warm the dish until it is hot enough to melt paraffin wax. Pour some melted paraffin into it, and tilt it about till the bottom and sides are evenly covered; pour off the surplus, and when dry you can use for toning, developing, or even silvering paper. Of course the above is only recommended as a substitute for glass or porcelain when the latter cannot be readily obtained. *Paraffin* alone may be used if you like. I use the Scovill japanned developing trays, and find it advantageous to varnish them with thick shellac varnish now and then.

I use 5 by 4 plates in my 5 by 8 camera. Get out some slips of ⅛in. walnut, 5in. long by 2in. wide. Slip one piece down the grooves for the plate, then the plate, then another slip. This prevents reflection. I also use a mask fitting into the back of the camera; but this is not absolutely necessary.

## SCIENTIFIC SOCIETIES.

### CHEMICAL SOCIETY.

AT the meeting of this Society, held on February 19th, Dr. W. H. Perkin, F.R.S., President, in the chair, papers were read as follows:—"On Benzoylacetic Acid and some of its Derivatives." Part II. By Dr. W. H. Perkin, jun. "On Toughened Filter-paper." By E. E. H. Francis, in which it was stated that filter-paper which has been immersed in nitric acid, rel. den. 1·42, and washed with water, is remarkably toughened, the product being pervious to liquids, and quite different from parchment paper made with sulphuric acid. Such paper can be washed and rubbed without damage, like a piece of linen. The paper contracts in size under the treatment and the ash is diminished; it undergoes a slight decrease in weight and contains no nitrogen. Whereas a loop formed from a strip 25mm. wide of ordinary Swedish paper gave way when weighted with 100grams. to 150grams. a similar loop of toughened paper bore a weight of about 1·5 kilo. The toughened paper can be used with the vacuum pump in ordinary funnels without extra support, and fits sufficiently closely to prevent undue access of air, which is not the case with parchment paper. An admirable way of preparing filters for the pump is to dip only the apex of the folded paper into nitric acid and then wash with water; the weak part is thus effectually toughened. "The Detection and Estimation of Iodine." By Ernest H. Cook, B.Sc. (London). The usual tests for iodine when existing as an iodide are rendered somewhat difficult by the circumstances that nitrous acid liberates bromine as well as iodine; while if an excess of chlorine be employed, colourless chlorides of bromine and iodine are formed. These difficulties become of importance when it is desired to detect small quantities of iodides in the presence of comparatively large quantities of bromides, or when a quantitative estimation is to be made of the iodine. To avoid these difficulties, the author proposes to use hydrogen peroxide, which is added to an acetic acid solution. Under these circumstances, the whole of the iodine is separated from the iodide, while bromides and chlorides are unaffected. Details of the methods of employing the test for qualitative and quantitative purposes are given: in the latter case, the iodine is extracted by means of $CHCl_3$, the solution is washed with a little water to remove hydrogen peroxide, and the tritation of the iodine then performed in the usual manner. "Note on Methylene Chlor-iodide." By Prof. J. Sakurai. "A Quick Method for the Estimation of Phosphoric Acid in Fertilisers." By J. S. Wells, Columbia College. Finding the ammonium molybdate method too long and tedious when many analyses of fertilisers had to be done, the author has adapted Joule's citric-acid method as a gravimetric process. He employs two solutions: A, consisting of citric acid 900grams., ammonia solution (rel. den. 0·92) 1,400cc., water 500cc.; and B, a strong solution of magnesium citrate. 1gram. of the fertiliser is fused with sodium carbonate and nitrate, dissolved in nitric acid, and the silica filtered off. To the filtrate some of solution A is added, and the whole allowed to stand for half an hour; enough of solution B is then added to precipitate the phosphoric acid. For the author's experiments, a test solution was made up of sodium phosphate, calcium chloride, and ammonia-iron alum, so as to contain $P_2O_5$, 19·83 per cent., CaO, 25 per cent., $Fe_2O_3$, 3 per cent.; equal portions were taken for analysis, the comparison of his results with theory being given in a table. "On the Luminosity of Methane." By Lewis T. Wright, Assoc. M.I.C.E. Pure methane was prepared by Gladstone and Tribe's method by the action of the copper-zinc couple on methyl iodide. The gas was obtained free from methyl iodide vapour by passing it through tubes fixed in a horizontal position and packed with copper-zinc, which was kept moistened with alcohol, the alcohol vapour being removed by scrubbing with sulphuric acid. It was burned in a London Argand burner, the chimney of which was fitted with a cap for the purpose of limiting the air supply to the quantity most favourable to the development of luminosity. The methane flame was compared with a Methven Standard burner supplied with 18-candle gas—i.e., with a light equal to two sperm Parliamentary candles. The results obtained were—

| Rate of consumption per hour corrected to 60° F. and 30" B. cub. ft. | Candles observed. | Candles per 5 cub. ft. per hour calculated. |

"On the Oxides of Nitrogen." By Prof. W. Ramsay and J. Tudor Cundall. In this research it is shown—1. That the green or blue liquid obtained by the action of arsenious anhydride on nitric acid consists of a mixture of nitrous anhydride and nitric peroxide, in proportions depending on the strength of the nitric acid and the temperature at which the volatile liquid is condensed. 2. That if a dehydrating agent, such as sulphuric acid, be present in sufficient quantity, the distillate consists of pure peroxide, and that this process is by far the most convenient one for the preparation of the peroxide. 3. That if oxygen be passed over the blue liquid, the vapours condensed in a freezing mixture are still blue or green; a great excess of oxygen is necessary to effect conversion from nitrous anhydride into peroxide. 4. That when excess of nitric oxide is passed along with the peroxide into a cooled bulb, the trioxide is produced, the amount of trioxide depending on the temperature of the condenser. 5. The vapour-density of a liquid of a deep blue colour, containing about 30 per cent. of trioxide and 70 per cent. of peroxide, shows that the trioxide cannot exist in the gaseous state, but at once dissociates into nitric oxide and peroxide on changing to gas. The theoretical vapour-density of such a mixture was calculated from a formula deduced from the second law of thermodynamics by I. Willard Gibbs, which shows the relations between temperature, pressure, and vapour-density of the mixture of $NO_2$ and $N_2O_4$ in the gaseous peroxide; and it was found that the vapour-densities of a mixture of ($NO_2 + N_2O_4$) [partly present in the original liquid as peroxide, partly formed by the decomposition of the $N_2O_3$ present into NO and ($NO_2 + N_2O_4$)] with the NO produced by the decomposition of the $N_2O_3$, calculated by means of Gibbs' formula, are identical, within limits of experimental error, with those obtained by direct experiment. 6. The presence or absence of moisture does not appear to affect the reaction between NO and $O_2$. 7. It is probable that $N_2O_3$ undergoes dissociation with rise of temperature, even while liquid. Dr. Armstrong said that he had listened to the paper with great interest, as he had made numerous experiments on the subject, and had long been of opinion that $N_2O_2$ did not exist, at all events as gas. The authors' observations, whereby they were led to this conclusion, were of considerable importance, and it was to be hoped that ere long confirmatory evidence, that would more directly appeal to chemists, would be forthcoming. It was noteworthy that there was no recorded evidence proving the existence of $N_2O_3$ as gas. Gay-Lussac's experiments, published in 1816, showed that nitric oxide and oxygen only reacted in the proportions to form $N_2O_4$, and that reaction in proportions corresponding with the production of $N_2O_3$ only took place in presence of alkali. The method adopted by the authors did not suffice to prove the existence of $N_2O_3$, even as liquid, and their results could be equally well interpreted on the assumption that they were dealing with a solution of NO in $N_2O_4$. It was to be expected that $N_2O_4$ would be a good solvent of NO, as it appeared to be the rule that bodies which are related are easily miscible, phosphorus, for example, being very soluble in $PCl_3$, and sulphur in $CS_2$ and $S_2Cl_2$. One observation made by the authors did, however, support their view—viz., the observation that the blue liquid was with great difficulty oxidised by passing oxygen into it. In all his experiments, Dr. Armstrong had found that the reactions attributed to $N_2O_3$ could be equally well effected by a mixture of $N_2O_4$ and NO. As to the action of arsenious oxide on nitric acid, in his opinion, *nitrous acid* was *the* product, and the manner in which this underwent change entirely depended on the conditions. In dilute solution, NO would be produced in accordance with the equation: $3HNO_2 = 2NO + HNO_3 + H_2O$; but in presence of nitric acid the reaction $HNO_2 + HNO_3 = N_2O_4 + H_2O$ would take place, and would more and more preponderate the less the amount of water present. The addition of sulphuric acid would of necessity favour the latter mode of change. When $N_2O_4$ is passed into sulphuric acid, nitrosyl sulphate and nitric acid are formed; in presence of NO, the latter is reduced to nitrous acid, which also forms nitrosyl sulphate with the sulphuric acid, so that a mixture of NO and $N_2O_4$ in proper proportions precisely acts as though it were $N_2O_3$. Prof. Ramsay, in reply, said that he thought the production of a blue liquid on passing a colourless gas into a brown liquid was good evidence of the production of a distinct compound. (Peligot's experiments render it highly probable that the blue colour results from the introduction of traces of water.—H. E. A.) Numerous cases could be cited of the non-existence of compounds as gas which were well known as liquids or solids—chloral-hydrate, for example.

## WESTERN MICROSCOPICAL CLUB.

THIS club held its meeting on Monday week at the house of Mr. Francis P. Pascoe, F.L.S., St. Stephen's-square, Bayswater. The subject of "Parasitic Insects," many of which illustrate in a remarkable way the law of degradation which to-day figures so largely in religious apologetics as well as in scientific treatises, was the topic of the evening. Mr. Pascoe began by stating that his remarks were confined to insect parasites living at the expense of animal organisms. Any aberration from the normal form in such insects was due to an arrest of development, and not, as in the crustacean epizoa, to morphological change. Insect parasites might be divided into, firstly, those which pass their whole lives on their host—such as bird, pig, and ordinary lice (degraded forms of hemiptera), nycteribia—a spider-like, wingless form, living on bats (braula) (bee-louse), sheep-ticks, and fleas (permanently parasitical on cats, dogs, &c.), belonging to the diptera; and, secondly, those which pass only a part of their lives in their hosts. Of these the female of the chigoe, the only example, is free when young. Full of eggs, she burrows in the human foot (generally a negro's), and, unless extracted, there passes the remainder of her life. In the stylopidæ (bee parasites), the male is free as soon as it assumes its perfect state, the female remaining to give birth to another generation. But the most numerous of all are those in which both sexes pass the three earlier stages of their existence as parasites. Some deposit their eggs in the eggs of other insects—polynemæ on dragon-flies, ophioneuri on the white cabbage butterfly's, &c. The female of a sitaris (one of our autumnal beetles) lays its eggs in the galleries of a bee (anthophora). For six or seven months the larvæ, "active little creatures with six legs," remain in the lethargic state, and, consequently, without food. But the moment the anthophora lays an egg, the sitaris larva "springs upon it," and in the empty shell undergoes its first transformation, changing into a "fleshy grub," consuming the honey the bee had stored for its own young. In the botflies, another set, the females lay their eggs where they may be swallowed by their host, and passing the larva and pupa stages in the digestive organs, are voided in the imago state. The third set, laying their eggs mostly in caterpillars, only emerge after they have completely eaten all but the skin of their victims. They belong mostly to the hymenopterous families, ichneumonidæ, proctotrypidæ, and chalcididæ (including about 2,200 British species), and the dipterous tachina and its allies. An anomalous beetle—rhipidius—is parasitical on the cockroach. In conclusion, the speaker called the attention of the meeting to some photographs sent by Mr. Curteis, especially to one which might have passed for a representation of a polyzoon, though it was merely a cluster of the eggs of a bird-parasite.

The members then visited Mr. Pascoe's biological museum, and saw many preserved specimens of the various animals upon which the parasites prey. Mr. A. D. Michael exhibited, amongst other specimens under the microscope, a beautiful slide of Ornithornia avicularia, a curious two-winged parasite having other bird-parasites attached to it. Mr. E. Bartlett showed some curious living aphides. The parasite that gave rise to the itch disease, known as Sarcoptes scabei, was shown in its various stages of development by Mr. G. C. Karop. Under a very sharp German microscope, by Leitz, Mr. E. M. Nelson exhibited, by means of an ingenious and very inexpensive condenser lately devised by him, the punctured markings within the reticulations of the diatom Triceratium septangulatum. This was accomplished with only a two-thirds object-glass. The next meeting of the club will take place on April 13, at the house of Mr. H. V. Tebbs. Subject, "Crystals under Polarised Light."

**Bicycles and Tricycles.**—Mr. Devey, of Wolverhampton, has found it necessary to take larger premises, and has accordingly removed to "The Ashes," where, in addition to putting down the best machines procurable for the manufacture of "cycles," he has also laid a good track, on which every bicycle and tricycle can be thoroughly tested before it leaves the works. Mr. Devey's list of "fittings" will be useful to amateurs desirous of constructing machines for themselves.

As in the case of the Health Exhibition last year, the exhibitors at the coming Inventions Exhibition are to aid in the selection of the juries.

## SCIENTIFIC NEWS.

THE annular eclipse of the sun on the 16th inst. will not be visible in Europe, but will be well observed in North America, where the central line will pass over Lake Winnipeg and through Nebraska and Oregon. Mr. Ellery, of the Melbourne Observatory, is organising a small expedition to observe the total eclipse of the sun which takes place on the 8th of September next. The path of totality lies almost entirely over the South Pacific, and New Zealand is the only land whence the total eclipse will be visible. Its duration will not exceed two minutes and a half. The partial eclipse of the moon on the 30th inst. will be invisible in this country, as the moon does not rise at Greenwich until she has cleared the earth's shadow. She may, however, be observed slightly obscured by the penumbra.

Prof. T. G. Bonney, president of the Geological Society, will resign his post as secretary of the British Association after the Aberdeen meeting, mainly because the work demands more time than he can spare.

At a recent meeting of the Physical Society Mr. J. C. McConnell presented two notes on the use of the Nicol prism, in which he referred to the error in measuring a rotation of the plane of polarisation due to the axis of rotation of the prism not being parallel to the emergent light. The second note dealt with a new method of obtaining the zero reading of a Nicol circle. This is often defined as the reading when the plane of polarisation is parallel to the axis of rotation of the table of a spectrometer. A Nicol is fixed on the table, the light quenched by turning the Nicol circle, and the reading taken. The table is then rotated through 180deg., the light quenched, and the reading taken again. The mean of the two readings gives the results required. It was described how the error due to the want of symmetry of the Nicol might be found and eliminated. Mr. H. G. Madan exhibited and described some new forms of polarising prisms. The first of these is by M. Bertrand, and has been described by him (*Comptes Rendus*, September 29th, 1884). The other prisms shown were a similar one by M. Bertrand, described in the same paper; a double-image prism by Ahrens, described in the *Phil. Mag.* for January, 1885; and a modification of the latter by Mr. Madan. Mr. L. Wright pointed out, as a practical objection to M. Bertrand's prism, that it was very doubtful whether a glass could be obtained of so high a density as to possess a refractive index of 1·658, and at the same time be colourless and unaffected by the atmosphere. The principle of M. Bertrand's prism, too, was not new.

The ordinary general meeting of the Institution of Mechanical Engineers will be held on March 20, at 25, Great George-street, Westminster. The following papers will be read and discussed, as far as time will admit:—"On Recent Improvements in Wood-cutting Machinery," by Mr. George Richards, of Manchester (adjourned discussion); "Description of the Tower Spherical Engine," by Mr. R. Hammersley Heenan, of Manchester; "On the History of Paddle-wheel Steam Navigation," by Mr. Henry Sandham, of London.

The Statistical Society proposes to celebrate its jubilee on June 22 and 23 next.

In connection with the Exhibition of Inventions and Musical Instruments, it is not intended to issue special handbooks; but the various sections of the catalogue will have prefaces written by, amongst others, such authorities as Prof. O. Lodge for electricity, Mr. G. Snelus for fuel, furnaces, &c., Prof. Carey Foster for philosophical instruments and apparatus, and Mr. Vernon Harcourt for gas and other illuminants. Exhibitors of musical instruments will be allowed to give demonstrations of the tone of their exhibits on one day in each week. In connection with the railway companies, it is intended to use a map, time-table, and guide book, and make such arrangements as will enable residents within a radius of 20 miles to reach the exhibition without rebooking.

Messrs. O. Salvin, F.R.S., and F. Du Cane Godman, F.R.S., have presented to the Natural History Museum two valuable collections. One collection, presented on certain conditions, comprises the entire series of American birds brought together by those gentlemen, numbering upwards of 20,000 specimens, and illustrating more than any other collection in existence the life-history and geographical distribution of the birds of tropical America. No labour or expense has been spared in the formation of this splendid group of ornithological rarities. The other gift, which is unconditional, comprises a very fine collection of Central American coleoptera of the families of Cicindelidæ and Carabidæ. It contains 969 species, and, moreover, 7,678 examples, of which more than 400 are types of new species described in the work entitled "Biologia Centrali-American," now in course of publication by Messrs. Salvin and Godman. To this collection will be ultimately added, by gift, the remaining families of coleoptera, with other etomological specimens.

Mr. J. Mayall, jun., states that the ruling machine by which the late Herr F. A. Nobert, of Barth, Prussia, produced his extraordinarily fine rulings on glass, and about the construction of which there has been much mystery ever since the rulings were first brought to public notice at the Exhibition of 1851, has recently been acquired by Mr. Frank Crisp, secretary of the Royal Microscopical Society. The machine was exhibited at the meeting of the society last Wednesday. The diamond points and the memorandum book relating to them have also been acquired by Mr. Crisp, so that we may shortly expect an explanation of Nobert's methods.

Mr. Ellis Lever, of Bowdon, who recently offered a prize of £500 for a perfect safety-lamp for miners, has informed Mr. Thomas Burt, M.P., that he now offers a similar sum as a premium for the invention or discovery of an economical, efficient, and safe substitute for gunpowder and other explosives employed in the getting of coal. It would seem from this that the water cartridges and the lime cartridges are either not efficient or not economical.

It is said that an American who has recently been to Europe promises to produce a sensation among both gas and electric light companies in the United States. It is probable that the new light is a cheap water-gas used with magnesia burner-caps on the system of Clamond, which we illustrated on p. 444, Vol. XXXVI.

With reference to the article on natural gas (p. 1) it should be mentioned that it sometimes causes explosions. In spite of wrought-iron pipes with screwed joints, the gas escaped recently into some cellars in Pittsburgh, and becoming ignited, wrecked four houses and injured twenty persons. The Fuel Gas Co. are laying alongside their pipes a line of drainpipes in a stratum of charcoal which surrounds both. The gas which escapes finds its way into the drainpipe, and at intervals is burnt at a lamp-post escape-pipe—the flame often being three or four feet high. Another company places the gaspipe within a larger one, which is used as the supply-pipe for dwelling-houses — the leakage being found sufficient.

According to some experiments by M. Olszewski, liquid oxygen vaporising under a pressure of one atmosphere gives a temperature of – 181·4° C. With nitrogen a temperature of – 225° C was recorded under low pressure, the surface solidifying, while with liquid carbon monoxide the lowest temperature was – 220·5 C.

M. Dieulafait, in a paper presented to the Paris Academy of Sciences, states that the Equisetaceæ and other typical plants of the Carboniferous age, contain a much larger percentage of sulphur than those of the present time—a fact which he thinks affords an explanation of the presence of sulphur and sulphate of lime in coal, and indicates the plants from which it was formed.

Professor Hermann's apparatus for the valuation of lubricants consists of a perfectly cylindrical shaft, about 10cm. in length, supported in two journals carried by a branched support, which turns on a hinge, so that the shaft can be adjusted at an angle of 5° to 10° to the horizon; the upper end of the shaft carries a handle, whereby it can be rotated. To use the apparatus, a bent piece of the same metal as that to which the lubricant is to be applied, is placed astride of the shaft, and suitably weighted, and the number of turns of the handle requisite to cause it to slide along the shaft for a given distance with various lubrication are noted. The greater the distance travelled for a given number of revolutions of the shaft the more efficient the lubrication.

## LETTERS TO THE EDITOR.

*[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.]*

*All communications should be addressed to the* Editor *of the* English Mechanic, 332, *Strand, W.C.*

*All Cheques and Post-office Orders to be made payable to* J. Passmore Edwards.

⁂ *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks a vice from whence great inconveniences derive their original."
—*Montaigne's Essays.*

### THE APPARENT ENLARGEMENT OF CELESTIAL OBJECTS AS THEY APPROACH THE HORIZON—HANDBOOK OF THE MAPS OF THE ORDNANCE SURVEY—THE ORIGIN OF MAN—THETA ORIONIS AND DIVERS DOUBLE STARS—THE DOUBLE TELESCOPE—"NAM NUNC MORES NIHIL FACIUNT QUOD LICET, NISI QUOD LUBET."

[23918.]—A communication of very great scientific importance has been made within a recent period to the Académie Royale de Belgique, by M. Paul Stroobant, upon a subject which has excited the attention of astronomers and physicists from the time of Al Hassan, nearly 900 years ago, down to the present day. I refer to the apparent enlargement of the constellations, and of the discs of the sun and moon as they approach the horizon. The explanations hitherto given of this phenomenon, though, in the case of two of them, sufficing to explain it, have always been felt to lack something, and to be more or less unsatisfactory; and hence M. Stroobant's novel and ingenious investigation of this curious question cannot fail to possess interest to all who have devoted any attention to it. As the Belgian savant points out, four principal hypotheses have been devised to explain this appearance. The first assumes that the heavenly body is magnified by atmospheric refraction. This we may dismiss at once as nonsense. Refraction close to the horizon (or anywhere else in the sky) can never increase the diameter of an object. On the contrary, when the sun has just risen, or is in the act of setting, refraction *diminishes* his vertical diameter, leaving his horizontal one intact. The second hypothesis is that of Al Hassan himself, who attributed the apparent enlargement of the rising or setting constellations to the apparent figure of the celestial vault, of which he alleged the part touching the earth at the horizon seemed more distant from us than the zenith by a whole radius of the earth; and that, hence, intuitively regarding the sky overhead as much closer to us than that conterminous with the horizon, we fancy an object to be of greater dimensions when, subtending only the same angle, it is on that horizon. But, as M. Stroobant points out, we have no proof that the sun and moon look farther off; and, moreover, while from experience we can correct fallacious impressions of size derived from the diminution of angular magnitude in the case of terrestrial objects, we have no such experience to guide us in the case of the heavenly bodies. And this brings us to hypothesis No. three, which assumes that we not only derive a notion of the great distance of the sun or moon from us by observing them with a multitude of objects between us and them, but we get an irresistible idea of their size by comparing it with those objects. In answer to this, M. Stroobant bids us smoke a piece of glass lightly, but sufficiently to hide the landscape when the sun is setting, and then to regard him under that aspect. He will actually look bigger than when compared by the unaided eye with intervening terrestrial objects. Moreover, the sun and moon appear just as large on the sea horizon where there is nothing to compare them with. The fourth hypothesis assumes that as the sun or moon approaches the horizon it becomes less luminous, and hence looks farther off. This explanation M. Stroobant regards as containing a germ of truth, though by no means the whole truth, inasmuch that he alleges that in foggy weather the sun, when quite close to the horizon, does appear notably larger than he does when the sky is free from vapour. Having thus cleared the way, M. Stroobant proceeds to describe the remarkably ingenious experiments (first suggested by M. Houzeau) by which he believes that he has succeeded in showing that an actual physiological cause exists for the strange optical illusion we are discussing. I need only refer here to the final form these experiments took. In an absolutely darkened room he contrived an arrangement by the aid of which two electric stars were attached to the ceiling about 8in. apart. On a level with his eye were two similar stars, the distance between which could be increased or diminished at pleasure. The apparatus was so arranged that the distance of the observer's eye from both pairs of stars was identical. Now comes the remarkable thing. When the observer carefully adjusted the distance of the pair of stars on a level with his eye so that it should be apparently precisely equal to that of the pair in his zenith, it was found on measurement that the horizontal pair *were less than 6½in. apart* (or as given by M. Stroobant), calling the distance of the stars on the ceiling 100, that of those apparently subtending an identical angle at the height of the eye was only 81·5! Another observer made it 79·5. With this pregnant result to guide him, the author of the pamphlet now before me proceeded to carry out his researches among the stars themselves, selecting pairs at sensibly equal distances in the horizon and zenith, and afterwards measuring their real angular separation on one of Niesten's celestial globes. In this way, as the result of a number of observations, he discovered that the mean of the interval between stars on the horizon is 79·7, that of pairs in the zenith being, as before, 100. How M. Stroobant applies this strange physiological effect (in conjunction with the decrease of brilliancy invariably consequent on the thickness and light-arresting haze of the horizontal strata of air) to explain the apparent enlargement of sun, moon, and constellations, when on the horizon, everybody interested in the matter should go to his excellent brochure to learn. It is very well worth reading indeed.

Now that so many tourists in the British Islands employ the Maps of the Ordnance Survey, and especially now that the really beautiful 1in. reproductions of the 6in. map is coming out (but far too slowly, by the way) in instalments, I would venture to suggest that the Department might, with considerable advantage, issue a sixpenny or shilling pamphlet, describing the projection employed, the method of taking latitudes and longitudes off the map, and so on. It would very materially increase the usefulness of these maps to a considerable proportion of their purchasers, and would, I should fancy, command a pretty extensive sale. If this should meet the eye of Colonel Stotherd, I hope that he will not be above taking the hint contained in it.

I cannot help feeling that if "O. J. L." (let. 23874, Vol. XL. p. 559) will read the (so-called) "Mosaic" account of the creation with the same attention, and in the same spirit that he would study, say, Green's "Short History of the English People," he will discover that his attempted reconciliation reconciles nothing. In Genesis iv. 2, we find the two sons of the alleged first man and woman engaged in agricultural pursuits, which obviously indicates a very considerable advance in civilisation; primitive man being, as is notorious, a *hunter* and a nomad. The "lake-men" were the earliest inhabitants of the earth among whom we find any traces of agricultural operations. They are referred to the Bronze and Polished Stone ages. Besides, the very chronology and the genealogies to which the writer of the account commits himself, show the utterly mythical character of the whole story. As a simple illustration, read Genesis v., and note (from vv. 21-22) that Methuselah must have survived the Flood!

Mr. Ruthven (letter 23892, p. 10) can hardly do better than consult Mr. Sadler's letter (23891) immediately preceding his, for a reply to the question with which he commences. With reference to Mira Ceti, I presume that he is referring to Smyth's distant companion, of which, in the "Bedford Catalogue," the position angle is given as 88·9°, and the distance as 116″. I can find no record of ζ Tauri as a double star at all. The latest measures of 80 Tauri in my possession are those of Mr. S. W. Burnham in 1879, when the postion angle was 7·4° and the distance 0·57″; nor can I find any later measures of O.Σ. 98 than those by Schiaparelli in 1877, pos. ang. 209·9° and dist. 0·98″. There are three stars marked respectively $\delta^1$, $\delta^2$, and $\delta^3$ in Taurus. If ever it is fine again (which, at this present writing seems at least doubtful), I will try to identify the pair in this constellation. Since writing these lines I have made the attempt, and wholly failed to do so; a remark equally applicable to Mr. R.'s stars near 135 Tauri. He must give the R A.'s and Dec.'s of these objects.

Inasmuch as "Montmartre" (letter 23896, p. 10) personally appeals to me, I may say shortly that the area of the half of an 8in. object-glass would be very approximately 25·13in., and that of a 3⅝in. objective with a ⅝in. segment removed 8·51in. The gain in light, then, by the employment of the large object-glass must be apparent at once. I think it is quite possible, though, that the definition might be slightly finer with the smaller lenses.

Let me hasten to disabuse the mind of anyone and everyone who may by any conceivable possibility have been led into the supposition that Mr. Ledger (letter 23898) is the author of the letters signed "A Fellow of the Royal Astronomical Society" in these columns; and to testify that not only is he not the writer, but that he is not in the smallest degree in my confidence; in short, that I have never been indebted to him in the remotest degree for one single thought, idea, or suggestion that I have ever penned here. Besides, unless my memory is more than usually treacherous, my first letter appeared in Vol. I. of the English Mechanic in the year 1865, while Mr. Ledger's right to adopt my now familiar signature dates from Feb. 11, 1876. With regard to the particular matter which at present exercises him, I would just say that, if, instead of treating the question in the quasi-jocular spirit in which I did, I had characterised the conduct of the (present) Astronomer Royal in persistently attempting to pack the R. A. S. Council with his subordinates at Greenwich, in the language it deserves, I should, just conceivably, have done something really to justify the diatribe of your correspondent. Writing, as I do anonymously, I am guilty of no egotism, in using his own words, and saying that, merely as a matter of fact, I happen to be "a gentleman, *both* by birth and education," and that, alike by pedigree and social rank, I am in a position to know what is due to my station, at least as well as he can possibly teach me. His peroration might well be passed over in silence, but for the fact that it may conceivably mislead a few people who do not know precisely what it was that I attacked. By all means "let all that is said about science be gently said, with good taste and kindly feeling." No one would more heartily say Amen to this than I should. But it is a solecism to describe the electioneering arts employed to pack our governing body, as *science*, and a mere prostitution of that holy word to use it in any such connection. "You cannot," said the first Napoleon, "make omelettes without breaking eggs"; and if notice is to be drawn to a real abuse, it can only be so drawn by language which shall arrest attention. It must be an evil thing for any society to have a man gradually acquiring paramount authority in its management by the introduction of a number of his own subordinates. Be his scientific acquirements what they may (and I, for one, have invariably given my ungrudging testimony to their extent), I believe Mr. Christie to have shown, in more than one way, his singular unfitness to occupy a prominent part in the management of the Royal Astronomical Society; and, that being so, *I*, having the interests of *astronomy* at heart, rather than those of any of Mr. Ledger's or Mr. Christie's friends, have felt compelled to utter the plain truth. Were I to contradict at the time, and on the spot, any statement made by Mr. Ledger from his own pulpit, I should righteously subject myself to a pretty severe penalty under 23 and 24 Vic. c. 32, s. 2. He can, however, advance no cognate claim, to speak ex-cathedrâ here, or to teach me either what to say or how to say it.

**A Fellow of the Royal Astronomical Society.**

## ENCKE'S DIVISION IN SATURN'S RING.

[23919.]—Whilst observing with a 7½in. refractor on the night of 22nd December, 1881, I distinctly saw the division in the outer ring known as Encke's division. It was fairly conspicuous round the ansæ, but from these points rapidly disappeared. From the accounts of various observers, it would seem as if these openings in the rings were subject to variability.

**T. R. Clapham.**

## SOLAR PROMINENCES.

[23920.]—Amateur astronomers possessing only small optical means are often discouraged when reading accounts of observations made by the aid of much larger and more perfect instruments. Something can be done, however, by small means, and I have lately been attacking solar prominences by the aid of a 3¼ o.g. telescope equatorially mounted, and a 5-prism, direct-vision spectroscope, about 18in. long of good dispersive power, the definition of the o.g, being also excellent. Living far away from a well-appointed observatory, my first difficulty was how to attach the spectroscope to the telescope. I devised and had an adapter made, where A (Fig. 1) is a bar 9in. long, at one end of which is a hollow screw, B, which fits the end of the slipping tube of the telescope. At the other end is fixed a clip, C, which carries the spectroscope in such a way that the sun's image can be sharply focussed on the slitplate, which is never covered from view. Selecting a period of great solar activity in September, 1884, I fixed the spectroscope on to the telescope, adding to the dew cap a counterpoising weight and sharply focussed line F. I then placed the slit tangentially to the following limb of the sun's image, which was carefully focussed on the slit-plate, keeping the slit just "off" the limb by means of a fine, slow motion screw in R.A. on the equatoreal. The dark line F was, of course, reversed, and seen as a bright line, in which I soon detected what appeared as a wave-like motion from side to side. I then opened the slit of the spectroscope to nearly its widest, admitting the flood of light very carefully by means of the R.A. screw, and distinctly observed the form of the cloud-like head of a prominence in shape like as at A (Fig. 2), a smaller one B being close to it. I watched these for upwards of half an hour, when A gradually became smaller and smaller, and, as well as B, vanished from sight. The diameter of the sun's image as given by a 3¼ o.g. is necessarily small, consequently, the views of prominences obtained by such small means are shorn of the grandeur displayed by much more powerful optical appliances; but that their forms can be seen by the aid of such means as I have described is, I think, sufficient encouragement for the amateur to attempt them.

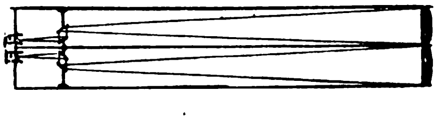
## DOUBLE TELESCOPES.

[23921.]—Referring to recent letters by your correspondent "Montmartre" as to double telescopes, would it not do to use two flats or reflectors for the purpose of bringing the image formed by two object glasses to the proper distance from each other to suit the eyes, as shown on the sketch inclosed, which is a section of telescope so constructed. It seems impossible that such a plan as this has not been tried; but if it has, will some correspondent kindly give the reason why it will not do?



**Thompson.**

## OBSERVATORY.

[23922.]—I was technically incorrect in my last letter (23897) in implying that, in the construction of the revolving apparatus in the great dome at Vienna, the live ring and flanged wheels were not used. The fact is both are used, but in such a way as to get all the advantages without the defects of those arrangements, as usually adopted. The usual "live ring" consists of a system of wheels, of which the axles are fixed between two concentric hoops or plates of iron, forming a double ring, so that the wheels and ring revolve together. These generally run in a groove on the wall-plate of the observatory, and a corresponding groove in the base of the dome. In this arrangement, any alteration in the shape of the dome is liable to cause a jam. The same may apply to flanged wheels, which may be caused from the want of power of adjustment in case of warping of the roof or dome.

In Mr. Grubb's construction at Vienna, the live ring consists of 20 sets of wheels, three abreast on the same axle, forming a continuous ring as usual. The outer and inner wheels revolve on two rails or projections on the wall-plate. The inner wheel is double flanged, to keep the ring from running off the rail. The outer wheel, without flange, runs on a rail, also on the wall-plate, and the central wheel without flanges, and which does not touch the wall-plate, carries the dome, the flat rail or projection below the dome simply resting upon it without any flange. We see here that there is no possibility of a change of shape in the dome causing a jam. The dome is kept in its place by a system of lateral, or, as we should call them, vertical rollers attached to the dome, and running against or near the trued inner edge of the wall-plate, and these are capable of adjustment as required. This is exactly the same principle as that described in my last, as the plan adopted in my observatory, the live ring of course not being required.

Fordingbridge. **T. Westlake.**

## THE STATE OF MAN.

[23923.]—Will "Priam" kindly say upon what authority he states that the tradition of creation, &c., was unknown to Moses, and was brought back by the Jews from Babylon? I have read of this before, but have never seen it stated whence this theory originated.

If creation in six days was a Babylonian tradition, how did it originate? Whether it was a poetic fiction of Moses or of some Babylonian historian, the period of six days, with the rest upon the seventh, is at least a curious fancy. If Moses gave to Israel the Ten Commandments, which I do not think is generally disputed, whence came the fourth, in which the creation is so distinctly referred to?

W. J. Grey, F.C.S., does, I think, considerably overthrow my theory about primitive man, as I conceive that a city could hardly have been built by a savage race with no tools and less knowledge of the arts of construction.

The whole subject of primæval man is highly interesting, intensely difficult, and almost hopelessly inexplicable, especially when variety of type —not merely in colour, but in the very skull formation—has to be taken into consideration. Here "Ex uno disce omnes" will not stand.

**O. J. L.**

[23924.]—Will "Priam" (letter 23902) kindly give the authorities for the very interesting statements he makes relative to the two first chapters of Genesis?

**B. F.**

[23925.]—Why does "Priam" waste space in your pages with his suggestions? Of course, the story of Adam and Eve is Mosaic, and all the objectors in the world cannot dispute it. Does "Priam" think that his anonymous opinion will suffice to supersede the testimony of the highest authorities of the last 6,000 years?

**John Hampden.**

[23926.]—The pages of the English Mechanic are not suited to a theological discussion, but I may, perhaps, be permitted to suggest to "Priam" that in the Commandments given by Moses, the creation of the earth in six days (or periods) is alluded to (Ex. xx. 11), and that he was, therefore, acquainted with the "legend" or "ballad," as "Priam" calls it. Whether the account of the Creation is superior "in *grammar* and imagery" to many other parts of the Pentateuch is a question which competent Hebrew scholars would probably decide differently from your correspondent. I will not enter into the *quæstio vexata* of the date of the Pentateuch; but anyone wishing to study the subject would find ample proofs that these books were written long before the return of the Jews from captivity.

**Otter.**

## THE STATE OF MAN.—TO "O. J. L."

[23927.]—I do not answer you just in the form you ask, and yet, I think it is what you require. Scripture chronology, as commonly accepted, is certainly *not* utterly and hopelessly at fault, as you suppose; the fault lies with the scientists in *not* putting events in their proper form and order. Allow me to explain. I presume you are aware that during geological times climatic changes were produced by the *internal heat of the earth* and *not by the sun*; and, I suppose, you are also well acquainted with Laplace's nebular hypothesis of the solar system? Well, place God at the helm of affairs, and you have in all probability the way the world was brought into existence, though for a long space of time afterwards too intensely hot to permit of life, or even of water, in which, according to geology, the first dawn of life appeared, and which was succeeded successively, as further cooling took place, by higher forms and types until, as is well known, a glacial period put an end to it all by the world becoming frozen desolate and *dead*. It is after this period that man appears, at least there is no *reliable* record of his earlier appearance, and not likely to be in face of the Scripture narrative, for the *present* world is a re-creation from the *past* Critically examine Gen. i., and you will see in v. 2, "the earth was without form and void." The original Hebrew word is, I believe, tolu, or loose atoms; or, in other words, it was chaotic, formless, utterly unsuitable for life in any way, and empty, but in existence. And it adds, "And darkness was upon the face of the deep." So you will see that this present world was *not* created out of nothing, as is usually supposed, but that it is really a re-creation from the old dead geological world which it follows in point of time; and the reason why geological times are not mentioned in the Scripture is simply because it commences only with man's advent; so that your question as to man's condition after the Fall takes its proper place, as a matter of course, when viewed in this light. I may say that the word translated "lights" in Gen. i. 16, is essentially different from that translated "light" in v. 3, and that it means an *instrument* of light to reflect the light to us, the light having been made first and then put into the instrument; and I think that I am correct in saying that it is pretty well understood now that light has always been in existence, in a more or less perfect state, *independent* of the sun; so that probably the light of the geological times was in accordance with the times, and not as perfect as now. There is much that might have been added to this, but as it would have been more theological than scientific, it would not have been suitable for the pages of the MECHANIC. In conclusion, I may say that in the *Christian Million* of a week or two since it is stated that an astronomer of some note is about to give a series of lectures, and amongst other things will give proof that there was *no* moon until the fourth day of creation—ours, of course; and by the Transit of Venus also prove that there have been weeks of seven days ever since creation, so that Gen. i. 2, should probably read, "And (*after the ages foregone*) the earth was without form, and void, &c.," that is to say, the geological ages. **J. H.**

## BEES.

[23928.]—SUCH of our readers as are interested in bee-keeping may be glad to know that much loss of life may be avoided by having the space immediately in front of the hive, and, if possible, for some little way on each side of it, covered with a layer of "slack" (the refuse of coal). This material, by absorbing the warmth of the sun, maintains a higher temperature than earth or gravel, and keeps a dry surface, and thus enables many a labourer, exhausted by a distant journey, or blown down by a rough wind, to rise again and regain the hive. I do not know that there is any novelty in the plan, but am sure that it is successful. **T. W. Webb.**

## VIOLINS.

[23929.]—"ORDERIC VITAL" asks: "When we read accounts of the fine qualities of tone attained by the old masters, are we to believe that every violin made by the Amatis, &c., is an excellent instrument?" The reply to this question cannot be too emphatic. Most certainly not. Only a small proportion of these instruments possess those high qualities of tone which have made their maker's name famous. The tone of many of them is nothing more than "ordinary." It has always been the case in fiddle-making that some instruments have turned out well and others the reverse. Stradivarius lived to the age of about 90, and as he worked from the age of 24, he must have made a large number of instruments. No doubt the best have survived (these survivors varying in quality), and the rest have gone to the wall. Time and use will improve every instrument, but will never make a bad fiddle a good one; and a new fiddle, if good, will show itself to be good from the very first, though nothing but time and use will mature the tone. It is true that no one has been able to improve on the model of Stradivarius. There is no definite standard of size for the fiddle. All the great makers made in two or three different sizes; but the "Grand" model of Stradivarius is generally considered to give the best combination of good qualities. The curves of the belly and back are not spherical in any violin, and vary very considerably with different makers. "Orderic Vital" may rest assured that it is next to impossible to think of any alteration or improvement in the violin which has not already been thought of and tried. Instruments of the best makers have been dissected, measured, and faithfully copied times without number, and with very varying results, the chief being that no one has yet succeeded in rivalling the originals. The Cremona violins will not, however, last for ever, and we shall have sooner or later to fall back on more modern instruments. Charles Reade, the author, in a pamphlet entitled "A Lost Art Revived," says, "The fiddles of Cremona gained their reputation by superior tone; but they hold it now mainly by their beauty. For 30 years past violins have been made equal in model to the *chef-d'œuvres* of Cremona, and stronger in wood than Stradivarius, and more scientific than Guarnerius in thicknesses." Although this is perfectly true, it must be borne in mind that these instruments will require the maturing effects of the lapse of 100 years or so before they can equal (if they ever do) the best of the Cremonas. In the mean time a picked few of the instruments of the great makers stand out in proud distinction as possessing a quality of tone superior to all others. A Stradivarius possessing the highest qualities of tone, and in good preservation as regards wood and varnish, will always command an ever-increasingly high price. Happy is the man who, I will not say, has his quiver full of them, but happy is the man who is the possessor of *one* of them; for nothing is easier than to pay anything under £1,000, and to find that you have *not* got one of them after all. **A Country Parson.**

## REFLECTING TELESCOPES FOR DAY USE.

[23930.]—WITH reference to Dr. Royston-Pigott's interesting "Notes on the Cassegrain" (page 3, Vol. XLI.), I must say that I think he is not right in recommending reflecting telescopes for day use, more especially for coastguardsmen. Some time ago I experimented with a small Gregorian as a portable hand telescope, and found it a great nuisance. To begin with, the mirrors *would* get out of adjustment when the telescope was carried about, and I much doubt the capability of a coastguardsman to adjust them. Then it was wonderful how fast the speculum metal tarnished with everyday use, and I should say the silver-on-glass would tarnish almost quicker, judging from my own experience with such mirrors. When the telescope was first taken out of doors, and a strong wind happened to be blowing, the mirrors would dull every time a blast of air entered the tube, till they had assumed the out-door temperature. And suppose the coastguard to be furnished with silver-on-glass Gregorians, where would Dr. Royston-Pigott propose to have the mirrors resilvered when tarnished, and would he keep a duplicate stock to issue while the operation was going on? I fear it would be pretty expensive.

I quite agree that the ordinary Coastguard telescope is a marvel of clumsiness and worthlessness; but the Royal Artillery garrison stations are furnished in most places with really admirable refractors, which define so well that I have ere now used them with astronomical eyepieces on simple objects, such as lunar occultations and sunspots, and the way in which the British gunner treats these instruments is heartrending. If the day be hazy, and he cannot see well, he unscrews the object glass and polishes it on his jacket, with marvellous effect. I would give a reflector about two hours of existence in the hands of an untrained man.

To conclude, I do not think reflecting telescopes will ever supplant refractors for day use, even in skilled hands, and I speak from experience.

Tynemouth. **Garrison Gunner.**

## BORT.

[23931.]—I WANTED to point out the difference between the gem diamond, bort, carbonado or carbonate.

The gem diamond is a perfect crystal, either white or coloured, provided, if coloured, the colour is equal all over. Hence you may have a black or yellow or blue gem diamond.

*Bort* is generally applied to crystal, which is discoloured, i.e., not white, and yet not with an equal distribution of colour so that it is not classed as a gem. But bort, by the dictionary, is sometimes applied to splinters, either of the pure gem or the impure crystal.

Diamond dust is either the dust from rubbing one stone against the other, as in diamond cutting (diamond cut diamond), or it is the stuff (dust) produced by pounding (in a special apparatus) pieces of the gem or of the discoloured crystal called bort.

Now, corbonado or carbonate, though of the same origin (viz., carbon) as the gem diamond and bort, is not a real crystal. It is described as amorphous. Now, this carbonado is (or used to be) much cheaper than the bort, and was used for cutting millstones, and by me applied 16 years ago to turn, i.e., *cut* (not merely abrade) steel hardened as hard as fire and water could make it. I wrote to "Ours" on 4th January, 1869, and my letter was inserted; but I have not kept my old numbers, as they go to the Royal Free Hospital to amuse the patients. I fearlessly assert that carbonado is not bort. One is a crystal, and the other is not.

Does Dr. Edmunds aver that in diamond dust from any source he ever finds a crystal, i.e., a piece of definite shape with facets? If so, it determines that a diamond is made up of small crystals, a point which I am interested to know, and as to which I have read vapoury statements, but no absolute assertion of the fact.

I see Dr. Edmunds speaks of dust of diamond, bort, and carbonado, being used for "truing-up hard steel," i.e., lapping it, which never leaves it true.

I want to see the diamond gem or bort, as I have defined it, or carbonado, used to *turn* the hard steel (not lapped), and take off shavings—i.e., pieces which, under a strong glass, can be seen to be shavings.

Dr. Robinson, of Dublin, used his daughter's diamond to cut or turn, not abrade, the hard steel pivot of his telescope. This he described in "Ours" in 1868, I think: at least I find it referred to in my letter of Jan., 1869, as having been stated by Dr. Robinson "a short time since." I recollect that Dr. Robinson mentioned that the diamond was re-set in his daughter's ring after using it as he described. No diamond is useful to a glazier unless it has its original outer skin, which is harder than the inner stone. Writing diamonds are splinters of gem diamond or impure diamond, alias bort, but not splinters of carbonado. In 1869 I described the tool to hold the pieces of carbonado, which were fastened in by solder. I used it to true up (by cutting) a Welsh grindstone. Dr. E. seems to doubt that a diamond has been used for cutting, not lapping, hard steel. See Dr. Robinson and his daughter's diamond, 1868.

I venture to assert that no mechanic would ever use a lap (which abrades) if he can get a tool to cut; and, further, I assert that no lap work is absolutely true.

The letter I have referred to, as of 1869, was over the signature "B. P. A." **Z. Y. X.**

---

[23932.]—IN letter 23012, p. 13, Dr. James Edmunds mentions the black diamond for turning hardened steel. I have myself used it for turning and drilling this last fourteen years, and have made some hundreds of diamond turning tools and drills for different purposes, such as turning porphyry and granite, chilled cast iron, hard steel dies and cutters, Mushet's steel, &c., and am at present setting a saw 28ft. long, with bort $\frac{1}{10}$in. diameter for cutting granite slabs. Should be glad to give any information the Doctor or Mr. Wenham may ask respecting the black diamond for turning purposes, or show them proof of what can be done with it by proper angles and setting. **S. E. S.**

## LAMINATED ARMATURES.

[23933.]—ALTHOUGH we appreciate in every detail the goodly information of your worthy contributor. Mr. Chaster, *re* "Motor Construction," yet we think that he is a little hard on Mr. Jones's form of armature in calling it a "clumsy imitation of the Siemens armature." If Mr. Chaster means Jones's laminated H armature, we cannot agree with his remark at all, as it is our experience and candid opinion that this form of armature is a decided improvement upon the old solid type. In the first place, it does not heat; secondly, it is much easier to anneal and make up; and, thirdly, the circulation of Foucault's currents is in a greater measure prevented, and as to whatever slight rotary motion exists of any individual part, it is an easy matter to prevent by simply screwing the end plates tightly; and, again, we find it an easy matter to round off with the file any sharp corners which may be likely to destroy insulation.

As to not sufficient room for wire, we cannot see how this can be, as we have just wound one, which is now lighting 14 fives and giving every satisfaction, and found ample space for several layers of insulation, and we use another daily in driving our lathe, one-man power, which has given us no trouble.

We rather doubt whether Mr. Chaster has given sufficient attention to the making up of this particular armature.

With the worthy Editor's kind permission we will take this opportunity to thank your esteemed contributor, Mr. S. Bottone, for his prompt reply to our query a week ago.

South Tottenham. **H. Harcourt.**

## COMPARISONS OF TIDES.

[23934.]—THE results of a close comparison between theory and obervation in the matter of the tides during the past month, indicate the connection which always exists between the sea-level and the heights of the barometer when combined with the *direction* and *steepness* of the gradients, to which attention is directed in the daily weather reports issued by the Meteorological Office. The heights of the tides are based on the records of the self-registering tide-gauge on George's Pier, Liverpool, and may be relied upon for correctness, allowing for the difference of datum-line between that adopted by the Admiralty and the old dock sill. The first fortnight of the month was remarkable for a succession of *cyclonic* gales, and these gales, aided by an unusually low barometer, kept the level of the sea continually between 1ft. and 2ft. *above* its normal height. When this extraordinary elevation was allowed for, it was not difficult to predict the current height of tide from day to day; but navigation was much impeded, and ships scarcely liked to venture into port. The "diurnal inequality," however, still maintained its general superiority over atmospheric conditions, though, in certain instances, the sudden arrival of a depression from the Atlantic tended to interfere with it. This was particularly the case on the 8th and on the 11th inst. From the 13th to the 21st, the pressure was more distributed, and the predictions became more approximately correct. Very little *anticyclonic* action has prevailed, and the temperature has risen generally; but from the 21st to the end of the month the conditions have been very unsettled. Our attention was directed to *three* distinct depressions. The *first* arrived at the mouth of St. George's Channel on the 16th, causing not very strong southerly

Comparison of Tides at Liverpool (Fleetwood) for the Month of February, 1885.

| Date. | Calculation. | | Observation. | | Error. | Barometer | Wind. | Remarks. |
|---|---|---|---|---|---|---|---|---|

| | 27 | 6 | 27 | 3 | − 3 | 29·9 | N. | Fresh. |

winds in one place, but north-easterly winds in the Irish Sea. The *second* depression advanced from the Bay of Biscay on the 19th, causing southerly winds at the French stations, but north-easterly winds over the Irish Sea. The *third* was a deep and very large depression, causing heavy gales to the west of Ireland; but as the prevailing direction in these latitudes was *westerly*, the extended coast-line prevented the elevation of the sea-level to the *east* of it. This depression began to make its influence felt on the morning of the 22nd. It will be seen from these remarks to what large variations the tides are subjected, and yet in the midst of all this irregularity, they submit to the dominion of *law*; and when the range of tide is large, as is the case at Liverpool, the study of this law becomes not only possible, but most interesting and instructive.

*Fleetwood, March.*

## A NEW ZEALAND TELEPHONE.

[23935.]—The transmitter described by Mr. Howlett is the "Hunnings," which has been in use in England since 1878. The patent was bought by the London and Globe Telephone Company, who patented it abroad, and at the present time are using it for household and other purposes in France, Belgium, &c. It was also the instrument being used by Harrison, Cox-Walker, and Co., when they were attacked by the United Telephone Co., whose Edison patent they showed to be bad. The Hunnings transmitter is acknowledged to be the best instrument for use on all underground or other cables. The patent for it was bought by the United Telephone Co. with the English business of the L. and G. T. and M. Co. last year for £25,000 in cash, and ⅛ths of all shares or money received from new telephone companies, i.e., such as the new South of England Company.

It is probable the L. and G. T. and M. Co. have already patented it in Australia and New Zealand, and *now* hold all rights in it there, as elsewhere, except in the U. K.

**N. E. D.**

## ANHYDROUS ANALYSIS.—V.

### D. Separation of Metals of Class 3, Division I., from those of Class 4, *et seq.*

[23936.]—We will suppose the assay now to consist of a weighed alloy of bismuth (Class 3) with silver and gold (Class 4). A "floor" or "bottom" of a piece of charcoal, with convex underside, to fit the bottom of the oval cavity of the aluminium furnace; or of "charcoal paste" made according to Plattner's method of similar shape, is placed in the aluminium furnace, and the assay treated upon it with "a gentle O.P." (1, Fig. 88), when the "brown-yellow and lemon-yellow sublimate shading off to white" (p. 105) of metal (*i*) will be copiously deposited on the vertical Al plate, and upper surface of the furnace. This should be frequently brushed off and collected for weighing, if necessary. If there is the slightest sign or "streak" of a *rose-coloured sublimate*, the heat must be lessened by withdrawing the point of the pyrocone from the assay as above described; because this is a proof that silver (or metal *j*) has commenced to sublime (Table V. p. 107). If it is found impossible to avoid this loss of metal (*j*) without leaving behind some of the metal (*i*) in the alloy, the heat is increased by inserting O.P. and the rose, or, in a thick deposit, carmine, coloured sublimate is to be carefully scraped off, made into a paste with soda, and fused on charcoal with the remaining gold and silver alloy in H.P. (Fig. 87, p. 74). This is now weighed, the loss of weight being taken as equal to the proportion of metal (*i*).

### E. Separation of Metals of Class 4, Division I., from all those above it on the Table; from each other, and from Metals of Division II.

The above-mentioned alloy (platinum being left out of consideration for the present), having been freed from the volatile substances of Class 1 and from the metals of Classes 2 and 3, as above described, and assumed to be in the shape of a metallic "button" or ball, is placed on the clean and very slightly inclined (towards the operator) surface of the aluminium tray in position over the cavity of the furnace upon a small crystal of boric acid, which, when it fuses, will cause the ball to adhere mechanically to the tray, and not roll away.

The alloy ball in this position is now treated with P.P. (2, Fig. 88), directed precisely on the centre of one hemisphere or side of the alloy, so as to keep it in a constant condition of red-heat, but it is not on any account to be allowed even to begin to fuse. If it does, the assay is spoiled, and must be commenced *de novo*. It is hoped that when this valuable reaction in alloys becomes better known than it is at present, apparatus will be so constructed that the lamp and assay can be *fixed* in the proper position on a sliding scale, and the blast made constant by a hydrostatic or other machine, so that the operator may simply have to place his apparatus and assay at the proper distance from each other (which of course varies according to the object required) with the pyrocone directed at the proper angle upon the latter, and watch results.

In an alloy of equal proportions of metals (*j*) and (*k*), after the above operation has been carefully carried out, the exact hemisphere of a ball which has been kept next the source of heat (i.e., the point of P.P.) will be found a pure silver-white colour, whilst the back hemisphere, which has been kept away from the source of heat (although it has, of course, remained red-hot from the force of metallic conduction), will have become an equally pure gold-yellow colour; in fact, by this simple but efficient mode of "parting," the Au + Ag alloy has evidently been *disalloyed*, and we have now a hemisphere of pure gold on one side, and a hemisphere of pure silver on the other; apparently because the metal possessing the lowest fusing point will imperceptibly melt, and its semi-fluid molecules gradually flow towards the source of heat; remaining eventually on that side. But it is also evident that gold molecules must be *repelled*; so that the phenomenon would appear to be partly pyro-electrical.

I could scarcely believe the evidence of my eyes when, in 1871, with my mouth-blower (see "Pyrology," page 299), I discovered this fact, the certainty of which I proved by treating many different alloys in the same manner with a similar result; as e.g., an ordinary commercial pin, the fused alloy-ball of which, thus treated, exhibited a "backing" of pure copper. I even found, or supposed I could see through a powerful lens, that a paste of the mineral *cyanite* (which consists generally, or, roughly speaking, of one-third silica and two-thirds alumina, or, according to "Dana Syst. Min.," p. 375, $Al_2O_3SiO_2$), when thus treated on Al plate, showed minute glittering points or facets of silica next the soure of heat or pyroxidation, whilst the back seemed to consist of comparatively pure white, rounded alumina. This circumstance, however, remains to be proved as a fact, but there can be no possible reason to doubt the ocular evidence, as to the separation by this means, of differently coloured metals in an alloy, and I intend to exhibit specimens of these, thus separated, in the International Inventions Exhibition. A silver-gold ball was shown at the "Scientific Loan Collection" of 1876.

The operator has now got as his assay certainly not an *alloy* of metals (*j*) and (*k*), nor even a mixture of them, but what may be termed a metallic electrical connection—a great step towards separation, but still not complete separation itself. The exact mechanical separation of such a "connection," moreover, even supposing the pure metallic distribution to have been precisely hemispherical; or, in other words, that the alloy consisted in the first place of equal proportions, would evidently still be an exceedingly difficult problem to solve, as both metals are very hard to cut. I therefore propose to work out results thus: The assay consisting of the parted metals (*j*) + (*k*) is taken up and fixed in the pliers (Fig. 42, p. 42), so that either hemisphere, or part it is intended to determine (say silver in this case), is projecting clearly from the points of the pliers, downwards. This downward part is then firmly pressed into a properly made mould of loam, which is shaped with a knife so that it exactly covers the silver hemisphere and no more, and allowed to dry. When perfectly dry, silver nitrate (or pure silver in any shape) is fused with a mouth or hand-blower in the cavity, until the operator has a silver hemisphere (or cast) exactly corresponding to that part of his assay. This cast, when weighed ought to give a close approximation to the quantity of metal (*j*) of his assay. To determine the quantity of metal (*k*), it will, of course, be only necessary to deduct this weight from that of the whole assay.

In like manner, metals (*j*) and (*k*) can be separated from such other metals as (*w*) or (*t*), with which they may be found alloyed, and thus estimated as to quantity.

In concluding this brief account of the analysis of metals, &c., belonging to Division I., it should be mentioned that no account has been taken of the matrix or "gangue," as it is technically called, often obtained from mines, &c., with ores—the combined metals having been treated above as though they were simple alloys:—first, because metals of the first three classes are generally remarkably free from such matrix; secondly, because the ordinary process of reducing ores containing such matrix to simple alloys, and separating the gangue as "slag" by means of some reducing flux is well known, and need not be reproduced here. For assays in the small way, Plattner's reducing flux is perhaps the best. It is thus made: "Mix very thoroughly ten parts by weight of freshly ignited and finely-powdered sodium carbonate, thirteen of potassium carbonate, similarly prepared, five of powdered freshly-made borax glass (fused borax), and five of well-dried starch powder, and keep the flux in a glass-stoppered bottle, since it will be useless if damp." (Prof. Cornwall's translation of Plattner's "Probirkunst," &c., 1879). Of course, such reductions can be made in the aluminium furnace by using H.P. (Fig. 87, page 74.) All sublimates can be at once reduced to metal with this flux except that of (*a*.)

A detailed description of my proposed new method of *estimating* mercury in ores, &c., by means of the *amalgam formed on gold-leaf per acensum* will be afterwards given, with a figure of the simple glass apparatus necessary.

It must be remembered that the above is a mere outline, and by no means a detailed practical description, of new processes of separating metals by fire, and estimating them separately by weight, or loss of weight of the residue. Should I receive due encouragement and help at the hands of those who *ought* to help me, the analysis of each metal will on some future occasion be separately given from actual results, headed by an alphabetical list of the minerals in which it is most usually found. Meantime, there can be no doubt of the principles or *facts* upon which the processes rest, which have been proved long ago; and it can also be proved by the blowpipe and aluminium plate that there is a serious loss of silver and gold in the ordinary method of cupellation. **W. A. Ross.**

P.S.—The figure (Fig. 2, ENGLISH MECHANIC, No. 1,040, page 563) is intended to represent a furnace "charged" with boric acid, containing spherical calcium borates. The shading of the cavity is too dark to show this properly, in consequence of my having sent the sketch in pencil, instead of ink. —W. A. R.

### A PLEA FOR GOOD MANNERS.

[23937.]—I, FOR one, beg to thank Mr. Ledger for so courteously calling attention to the unpleasant reading to be found from time to time amongst the correspondence of the ENGLISH MECHANIC. While continually admiring the patience and unselfishness of many writers, I have frequently deplored the absence of good taste and kindly feeling in some letters upon the noblest subjects of physical science. **R. W. Oldham.**

Wellow, Romsey, March 9.

### BRASS AND GLASS.

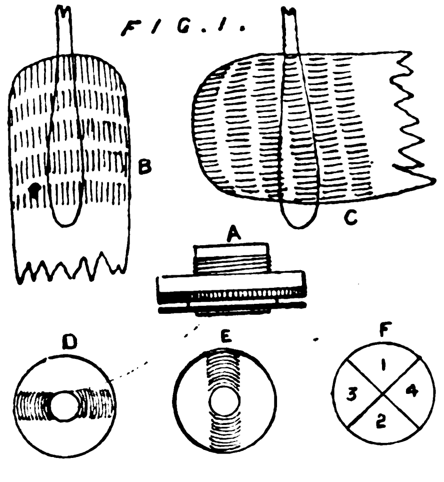
[23938.]—MAY I call the attention of the brass and glass section of your readers to a new revolving nose-piece I have designed for the purpose of testing the various sectors of an object-glass, which I exhibited at the Q.M.C. on the 27th inst.?

For long I have been of the opinion that all the sectors of an object-glass are not equally good in defining objects. Fig. 1 F, sectors 1 and 2, might not be as good as sectors 3 and 4. I have formed this conclusion from the study of the exclamation marks on the Podura, when viewed in different azimuths.

There was, however, always this difficulty—viz., that when the scale was rotated, the illuminating conditions were altered. B shows the relative positions of the scale and the flame, when viewed in the usual way, the achromatic condenser being accurately centred, and the edge of the flame carefully focussed on the object. D shows the position of the diffraction spectra seen at the back of the objective, the eyepiece being removed; in this case 3 and 4 F would be the working sectors of the object-glass. Now, if the scale be rotated through an angle of 90°, the exclamation marks will lie across the edge of the flame, as at C. The diffraction spectra will be turned round as at E, and a different pair of sectors, 1 and 2 F, brought into play. Assuming, for a moment, that the sectors 1 2 3 4 are all equally good, it is to be expected that the exclamation marks, as at C, would appear different to those at B, on account of the position of the exclamation marks with regard to the edge of the flame. Therefore, in the dissimilarity in the pictures, when a Podura scale is being rotated, something must be allowed for the alteration of the illuminating conditions with regard to the position of the exclamation marks, and something for the difference in the quality of the sectors. The importance of separating these variables will be obvious to every one. For this purpose I have designed a revolving nose-piece A, which will enable the object-glass to be turned round, and so bring its various sectors into play. By this means it can be easily demonstrated how much of the difference in the pictures is due to the objective, and how much to the illumination. When I practically tried this nose-piece, I was very much astonished at the enormous difference I found in the defining powers of the alternate sectors of an object-glass.

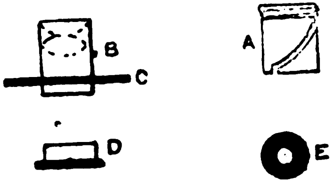
To illustrate the difference in the chromatic aberration, let me mention only an example. A very fair water imm. $\frac{1}{8}$, 1·17 N.A., showed the exclamation marks red in one position, but turned them green when the object glass was rotated through an angle of about 90°. The practical outcome of all this is important.

FIG. 1.



1. An object-glass which performed well enough when exhibited on the optician's microscope, might tell a very different tale when tried on the purchaser's instrument, because the objective might not screw up to the same point.
2. It may account for the difference of opinion held by experts as to the quality of any particular objective, for they might have been testing different sectors.
3. It would be worth while, in the case of expensive object-glasses, to have the society's screw portion of them capable of rotation, and provided with jam screws, so that the purchaser might place the better pair of sectors in a line across his own microscope, then fix it with the jam screws. He would only have to remember to place any exceptionally difficult object in a line with the front and back of his stand.
4. I think this appliance will prove useful in very delicate work, such as that carried on by the Rev. W. H. Dallinger.

FIG. 2.



The design has been most beautifully carried out for me by Messrs. Powell and Lealand, and I would like to draw attention to the flange $1\frac{1}{2}$in. in diameter, which secures perfect steadiness when the object-glass is rotated. Fig. A is drawn to the scale of $\frac{1}{2}$.

I now wish to describe a cheap form of condenser I have designed to meet the wants of students and others who use microscopes on the "Hartnach," "Student," or "College" models. It consists of a tube A, Fig. II., with a spiral slot cut in it, this is screwed into the hole in the microscope stage. A tube B C, carrying the lenses (a meniscus and a biconvex) slides into the other tube; a pin B fits into the spiral slot. A flange, with a milled edge, is fixed near the end of the tube B C, and at the end of the tube B C fits a cap D, like the lid of a pillbox, with a large hole in it. This holds a diaphragm E; I think that three sizes of diaphragms would be sufficient. At the Q.M.C. I showed a Leitz £3 12s. microscope, on which Mr. Baker had fitted one of these condensers; I exhibited some micro-organisms both with and without the condenser. The superiority of the picture when the condenser was used was admitted by all who saw the comparison. Fig. 2 is drawn to scale $\frac{1}{2}$. **Edward M. Nelson.**

February 28th, 1885.

P.S.—The flange, which is $1\frac{1}{2}$in. in diameter, is for the purpose of focussing the condenser by rotation, the pin B running up and down the spiral. The small vertical piece of the slot should be noticed, as it prevents one accidentally twisting out the condenser. The aperture is ·5 N.A.—E. M. N.

### LOCOMOTIVE DRIVING AXLES.

[23939.]—IN pursuance of a recommendation contained in Major Marindin's report on the Penistone Accident, a return has been published showing the number of driving axles in use and the proportion thereof broken or taken out during the year 1883, the details of which are given in the following summary:—

| Description. | Number in use. | | Broken in running. | | Taken out in shops. | |
|---|---|---|---|---|---|---|
| | iron | steel | iron | steel | iron | steel |
| | | | per cent | per cent | per cent | per cent |
| Crank axles *without* hooped webs | 2,867 | 4,733 | 3·1 | 0·9 | 6·0 | 3·8 |
| Crank axles *with* hooped webs .. | 4,121 | 1,222 | 0·85 | 0·9 | 7·7 | 0·7 |
| Straight axles, outside cylinders | 438 | 1,467 | 5·0 | 0 5 | 2·7 | 0·8 |
| Total driving-wheel axles.... | 7,426 | 7,422 | 2·0 | 0·8 | 6·8 | 2·7 |
| Total...... | 14,848 | | 2·8 | | 9·5 | |

The advocates of outside-cylinder engines frequently claim that they avoid the danger of a crank axle; but from the above figures it appears that 5·5 per cent. of straight driving axles broke when running. It is satisfactory to notice that a large proportion of defective axles were discovered and taken out in the shops, and doubtless a more careful and frequent examination will reduce the number "broken in running"; but still, growing flaws will exist, which no care nor investigation can detect. **Clement E. Stretton.**

Leicester, March 9.

### NEW BRAKES.

[23940.]—I OBSERVE in your issue of the 6th inst. that "Driver" (letter 23907) says I have made a mistake in saying that the new Midland brake is the same as that in use upon the Lancashire and Yorkshire Railway. I beg, however, to say that I have made no mistake in what I stated, as the latter company have for some considerable time past been fitting up and working with every satisfaction, a brake of exactly the same arrangement as that which is now being fitted to the Midland Company's vehicles. It is quite true, as stated by "Driver," that the Lancashire and Yorkshire Company have some vehicles fitted with the brake having a sleeve round the piston rod; but from inquiries I have made I find the type they now fit up is the same as the Midland are going in for, and I believe it to be the system which is preferred over any other. **G. Mitchell.**

[23941.]—IN your issue of the 6th inst., a correspondent on "New Brakes" says: "There are a lot of changes going on now," and then proceeds to enumerate several, but omits the most inexplicable of all. Everyone knows that, both in theory and practice, the Westinghouse automatic brake is the best. Then why are the G. and S.W. Railway, who have hitherto been staunch supporters of the Westinghouse brake, now engaged in trying a form of vacuum, with a view to fitting their stock anew? Perhaps Mr. Stretton will explain and oblige.

**W. B. Thompson.**

### THE NEW MIDLAND ENGINES.

[23942.]—YOUR correspondent, "More Expansion" (p. 540, letter 23853), ought to have the thanks of the railway company for giving his ideas on how to work the big engines which have been such "failures" for want of steam.

The plan of working expansively was fairly tested last Friday, Saturday, Sunday, and Monday; it is a strange thing, but those very engines that before had to take a pilot with twelve coaches now are running with sixteen, and have lots of steam; and a bit more practice and a sixteenth of an inch more lead which is now to be tried on "More Expansion's" suggestion will enable these fine engines to take the twenty coaches they were built for. The engines are right enough so long as you keep them well linked up; but the moment you put them in too forward gear to "push" them, they use more steam than they make, and they are soon short of steam. This correspondence shows more clearly than words the practical and scientific value of the information given in the ENGLISH MECHANIC.

It will perhaps interest your locomotive readers to know that during the past week not a second of time has been lost by any of the 19in. engines—they have even picked up some, and are burning much less coal than they did before the expansive working had a fair trial.

**Locomotive.**

### NEW MIDLAND ENGINES.

[23943.]—WITH your kind permission I should like to ask "More Expansion" a question or two. In his letter (23853, p. 540) he says as soon as a train is well away from a station notch up the gear, and work expansively; if steam-pressure falls in boiler still work more expansively, and attend well to fire. Now, Sir, suppose a man is going to work an express train for a distance of 100 miles, due to leave A at, say, 10 o'clock, pass B at 11 o'clock, and arrive at C at 12. He knows his engine is not very good for steam, so he puts a good fire on and gets it well burnt through, and puts as much water in the boiler as it will carry, and when the time is up to start, the engine just begins to blow-off. As soon as he gets well away he pulls up his lever in the second notch out of gear, and opens the regulator about three-parts of the way. When he gets 10 or 12 miles on the road he finds he is not keeping time, and the engine is not making enough steam, so he pulls up the lever another notch and gives her the whole of the regulator, and by the time he passes B he has dropped, perhaps, four or five minutes. Now what is he to do? Remember his engine was well up to the mark when he started, as regards steam, fire, and water, and now he has another 50 miles to go, with steam 20lb. to 30lb. lower in the boiler, and perhaps about an inch of water in his gauge-glass; he cannot give her any more regulator, nor pull her up any higher, so what must he do but keep going on as well as he can, and by the time he arrives at C he will perhaps be 10 or 12 minutes late, and perhaps got 60lb. of steam, and the water only just in sight at the bottom of his gauge-glass.

Now, Sir, "More Expansion" says it is the attempt to push an engine which causes all the trouble. He says you must not push them; but what is a man to do? He must have the time out of them either one way or the other; but if you cannot get the steam into a locomotive you cannot get the time out.

Now, Sir, I am not a driver, but if I live I shall be some day; and I should very much like to know how to go on if I was fixed in the way I have described. Hoping "More Expansion" will give his advice through these columns, I think it would benefit a good many more than one.

Lincoln. **A Fireman.**

### L. AND S.W. EXPRESS ENGINES.

[23944.]—I SEND dimensions of the new London and South-Western express engines, as requested by some correspondents:—Cylinders 18in. by 24in. (outside); dia. bogie wheels, 3ft. 4in.; dia. coupled wheels, 6ft. 7in.; wheel base, bogie, 7ft.; bogie centre to driving centre, 9ft. 11½in.; coupled wheels, 8ft. 6in.; boiler, length, 10ft. 2½in., dia., 4ft. 4in.; firebox shell, length, 6ft., breadth, 3ft. 10½in.; firebox, length, 5ft. 2⅝in., breadth, 3ft. 3¼in., depth, 5ft. 9¾in. 218 tubes 1¾in. dia., length, 10ft. $\frac{5}{16}$in. Heating surface—Tubes, 1051·13 sq. ft.; firebox, 110·18 sq. ft.; total, 1161·31 sq. ft. Boiler pressure 160lb. Weight about 46½ tons. Tender, six wheels 3ft. 9¾in. dia., holds 2,350 gallons and 3½ tons of coal. Weight, empty, 16 tons. These engines are Nos. 460–469 (Neilson and Co., 1884), 147, 470–478 (Stephenson and Co., 1884). **Meteor.**

### LATHE MATTERS.

[23945.]—F. H. WENHAM (23882), I would venture to point out, is wrong in stating that screw-threads cannot be cut by wheels.

The contact between a cutting-wheel and a thread is not a surface, but a line; a straight line in Dr. E.'s case. Mr. Wenham seems to mistake it for a surface. By cutting one side at a time, square, or even undercut, threads can with suitably-sized cutters be truly worked upon, theoretically and practically, by inclining the axes to one another of the screw and wheel. If there is an error, it is in the grinding speeds at apex and bottom of threads; with very light grinding it should be of no moment.

I prefer a bit myself as simpler and avoiding shake in bearings, though, perhaps, less clean and much less rapid in its action. I have found it useful, though perhaps the practice is old, to bend bits or finishing tools cold out of the cut, so that when stress comes on them (up to the limit of their stretching), they remain rigid under it.

**Vulcan.**

### LATHE MATTERS.

[23946.]—MY contributions to the ENGLISH MECHANIC during the past fifteen years have been on subjects I have practised and which I can vouch for. I am reluctant to speak of matters relating to myself, but as I am held up as a paper theoriser by one of this class, who writes beyond his knowledge, I am constrained to say that I do not appear as a mere amateur. Several years of my minority were passed as a pupil in the drawing office of a firm of marine engineers and shipbuilders, and as long ago as 1845 I was in business on my own account as a maker of marine engines and machinery. For improvements in these engines I obtained a prize medal at the International Exhibition of 1862, awarded to me by jurors, themselves marine engineers; and until quite recently I have been more or less connected with machine shops. I have made lathe mandrels innumerable, from the heaviest to the smallest. I repeat my assertion that some of the best makers of foot lathes do true up their hardened mandrels by means of diamond cutting tools. I shall not attempt to obtain a gratuitous advertisement in these pages for any maker, or make him the subject of coarse contradictions and verbose controversies, or submit his mandrels so finished for any self-constituted juror to "report upon," for the competency for such an office is usually to be judged by others, and not by the individual himself; but if any reader of this requires a lathe as accurately finished as a lathe can be, and will give his direction in the address column, I will show him two lathes with traversing mandrels which have been trued up with diamond turning tools. The manufacturers are in an extensive way of business, and make this kind of lathe a specialty, at very moderate prices. I have also used diamond turning tools both for turning up hard mandrels and for cutting back the shoulders of lathes that have been misused from having long worked with a slack back centre.

To flat contradiction No. 2, I reply that it is not a "real fact" that pieces of diamond of the proper shape are "extremely difficult" to set so as to be held safely. On the contrary, it is a remarkably easy operation to do this so securely that the splinter will rather smash up than leave the setting. This operation, by which I have set numbers, occupies but a few minutes. I have on a former occasion explained the method, and if correspondents desire it will do so again. Diamond tools cut the very hardest steel "sweetly," requiring but a light pressure: and I am about to apply them for giving a finished surface to parts of mechanism in wood, as their ever-enduring keen edge would save the trouble of the constant sharpening and readjusting which steel requires. Again, this questionable authority at once condemns the use of the roller for bedding down diamond particles in laps and slicers, an instrument which it is apparent that he has never used or seen. As the owner of a lapidary lathe, with all the requisites, that I have long used for shaping and slicing different kinds of materials for optical and philosophical purposes, I am in a position to state that a narrow hard steel roller does bed in the diamond more effectively and economically than the agate rubber, and I prefer to use it, as a very heavy pressure can be given to bury the large particles. This is not my own idea, but was recommended to me, and I at once got the tool made.

And now let me give a friendly hint to Mr. Hines, if he has any regard for his reputation, to act with caution in being prompted in any argument for cutting screw-noses and taps by circular cutters, and finishing them up by similar grinding laps. Take, for example, a deep V or square-threaded screw of coarse pitch, for a sufficiently palpable experiment; have a circular saw or cutter the width of the thread space which is to gauge the same from top to bottom. To use the saw with its plane at right angles to the axis of the screw would be utter folly, but with all care in adjusting the circular cutter to the screw angle an inaccurate form of screw will be the result. Neither by theory nor practice can a perfectly symmetrical screw-thread be obtained this way. Let anyone take a circular disc of metal turned just to the gauge of a square screw-thread of coarse pitch and drive it into the bottom; the kind of twist that it has taken at the place will then be seen. This is the effect in practice; but there are several who write for the ENGLISH MECHANIC who can readily demonstrate this mathematically. I have just had a case in point. Having had occasion for a pair of wheels on the silent or skew gear principle, in which the driving and driven spindles cross over each other at right angles, although I had got a circular wheel-cutter just to suit the form of cog that I require—these wheels, in fact, being multi-threaded screws of coarse pitch—this cutter could not in consequence be used, nor could a fly-cutter, so I made a kind of grooving drill of the contour between the threads, which cut the spaces accurately, but into which the circular cutter would not fit.

I am aware that circular discs, charged with emery or diamond dust, are used for cutting screws; but on what? Such as bottle-necks and stoppers. A short time ago I cut a screw on a porcelain cylinder for a gas-burning experiment, using a diamond-charged disc; but the form of such screws as these is of no consequence, so long as they hold the work securely together.

The "prussiate" case-hardening, as applied to soft iron, is almost a useless process; it acts in blotches, and raises the surface, and, at the best, the hard skin can be taken off with a vigorous rub with an old file; but for homogeneous mild steel, treated in the way that I have described, after being dusted continuously at a blood-red heat and quenched, it has an unimpaired surface, without scale, looking as if the steel had been merely oil-stained.

About two years ago I purchased a strong 6in. foot lathe, because it had a very convenient form of overhead gear, and included a number of cutter and milling frames, circular cutters, and other useful traps; but the mandrel was one of the detestable iron sort, with steel welded ends, and, as the screw-nose was a mongrel thread, I determined to make a new one, as the chucks would bear cutting out to the Whitworth standard. This mandrel was treated and hardened just as I have described, the cone fitted throughout in the collar, just as it was finished to do while soft, and so accurately that I have not found it necessary to grind it in; its own work soon made the bearing right, and as for hardness, no file will touch it, and it cannot be indented, as the softer steel below has been indurated by the heat. I will give Mr. Hines an opportunity of exercising his candour. When he is next in this city I shall be glad to produce the mandrel, and defy him to indent it on the hardened part with a centre punch and hammer. As to swaging in the fire, I take care never to allow this, or have an overdone side. I am too old a smith to make such a stupid mistake—with a blood-red heat, too! If Mr. Hines says that he is unable to make a mandrel so as not to warp or cast, we may take his word for it; but if he states that it cannot be done by others, then he must expect contradiction. I see no reason why, with proper metal and suitable treatment, mandrels should not be as true after hardening as before; but, in these cases, the nautical and astronomical terms so learnedly and humorously applied to the eccentricities of a drunken mandrel would be wasted. I take it that finishing up with diamond tools is a modern and not an old practice; the delicate fine lines left on the steel are soon taken out by the screw grinding clams, and there is no such perfect way of finishing up cylindrical rods as this.

I have no interest in looking at the model mandrel named at the soirée; the drawing, which has appeared again and again, is sufficient, and which is to be seen once more at page 562 of this journal for Feb. 27, for the design is objectionable. In the first place, the most important part of the screw is sacrificed for the sake of the cylinder at the base of it. This is of no use if a screw is to be got true; for acting as this does as a series of reverse cones to bring the chucks against the mandrel face, it forms a good centring agent in itself. If the cylinder is true and the screw is not, we have always one part struggling to destroy the truth of the other. Again, the face of the mandrel is needlessly large, which would cause it to cast in hardening. The nearer that we can approach uniformity in size and material, in steel work to be hardened, the less likely it is to warp, and this error will be worse in the model mandrel by the extra diameter given by the useless rounding of the periphery of the face. A lathe mandrel should be cut out of the rolled bar, without any forging whatever; if steel is hammered or swaged, and condensed more in one place than another, such parts are sure to warp or swell up in the hardening, however well annealed beforehand. Perfect homogeneity is what we require.

**F. H. Wenham.**

### AMPHIPLEURA PELLUCIDA AND DIFFRACTION (No. I.)—TO MR. P. A. PHILLIPS.

[23947.]—THE question now raised is a very complex and difficult one; it involves diffraction and the laws of the *minimum visibile*.

On the general question it is here impossible to enter. I must, therefore, confine my remarks to facts. It is interesting to note the stages of opinion through which the subject has passed. Fraunhofer was the first to state, in his admirable paper on Light, his strong belief that on the wave theory some of his finest rulings on glass would be quite beyond the power of the microscope to resolve. Sir John Herschel (Art. "Light") declared he thought Fraunhofer's statement unwarranted by his formulæ, and that a much smaller thing would be visible. Helmholtz next stated that in the case of brilliant discs about half a wave-length appeared the probable limit; but there might be circumstances which would reduce this limit still further.

The whole thing hinges upon the original hypothesis of brilliant discs. These swell out under microscopical examination. An infinite number of experiments on this question may be sustained. Here is one of the simplest:—

1. Place a "beetle's eye slide" on "the stage," form an image behind it of a small lamp-flame by means of a ¼in. objective. As you withdraw this image further from the slide you will see the flame image gradually diminish, till with the best powers you have you will find that this image soon reaches *a small limit beyond which it will not pass.* You will now see innumerable brilliant dots of light surrounded by faint diffraction rings. The focus of the facets I measured at 1-1000th of an inch.

2. Place at four yards distance in a darkened room before a brilliant shaded flame a piece of brass punctured with holes arranged closer and closer. Miniature these holes brilliantly illuminated by means of a fine ⅛th objective attached beneath the stage. Bring the image of these holes under the focal plane of the microscope. You will see that the closest (and perhaps the next pair) entirely *coalesced*. The finest pair have vanished. Two things may here subvent the phenomena—first, the diffraction swelling of the bright discs; secondly, the lateral residuary aberration produced both by the observing and miniature forming lenses. (All these things have been most carefully measured.)

3. If your eye can bear the effulgence of a miniature of the brightest *sun* brought upon the stage, you may repeat the following experiment:—

An Amici prism, focus 3in., is placed in bright sunshine, so as to form an aërial image of the sun, about four yards from your microscope, placed horizontally. You will require a mechanical substage to carry your ⅛th objective, so as to bring the miniature of the sun exactly in view of the observing microscope armed with a ⅛th. If you have a good spider line micrometer, you will find a magnificent measurable solar disc (and if your glasses are good enough) surrounded with an intensely black ring. Size of disc, 1-16000th; thickness of black ring, 1-50000th. But by trigonometry the sun's disc is now four times larger than it ought to be. (I am away here from all my data.) Here, again, the spurious disc is greatly enlarged. This enlargement is compounded of residuary aberration, if any, and diffraction.

The phenomena presented by aberration and diffraction have now been pursued about twenty-three years, with ever-increasing interest. But while one class present themselves with an effulgent brilliance which no words can describe, another distinct class can be observed when *brilliance is dissipated.* An overpowering diffraction outblazes minute details in the miniature, which at once start into view by withdrawal of the sunbeams. And the possibility of a *minimum visibile* being examined and measured becomes at once apparent.

I recollect, when a medical student, the pains required even by old Topping to exhibit the squares of the Hippocampus. And after a great amount of conjuring with the concave mirror, at last the cross striæ of the lattice appearance of the Angulatum were visible. To what causes were these difficulties ascribed? That would be an interesting text. I was once on the point of buying a 1-16th Ross. This glass, however, persisted in exhibiting the markings on P. formosum as elongated squares (parallelograms). Was this diffraction, or bad spherical correction, or incorrect centring of the system of lenses, or all combined?

To bring this answer to a close, I must point out that brilliant points or lines are the grand sources of diffraction, and mild equable illumination its general abatement.

I have lately seen letters, spontaneously written, in praise of certain American glasses, in which it is boldly declared the markings on Amp. pellucida have been displayed without a condenser, and with *very little obliquity of light from a concave mirror.* If this be so it must be ascribed to great perfection in the spherical and chromatic corrections and mechanical work of the objective. As years rolled by, I have constantly observed improvement in objective quality, followed by less elaborate illumination. The pin-hole stop gives a direct cone of light of very small aperture, say 15°, and this is a most severe test of quality. I found it serviceable with my 1-50th of Powell and Lealand, and I have used largely condensers formed of a battery of objective glasses ranging from 10° to 140° for the last twenty-five years, and often with immersion fluids both above and below the slide, so as to produce as far as possible equivalent mediums (now called homogeneous) and allow the rays to penetrate with the least possible deviation. On another occasion I propose to speak of the reduction of diffraction and the minimum angle visible more in detail. For instance, Messrs. P. and L. once showed me with their 1-80th the veritable dark dots of Amp. pellucida. The dots were very much smaller than the interspaces. What angle would these dots subtend?

Note.—My Amici prism has a 3in. focus. Taking the sun at 30 min., diam. of 1st disc = 3 sin. $30' = 3 \times \frac{1}{114}$. Then this disc is miniatured down by ⅛th objective placed at 4yds., or 144in., to a minute size, 144 × 8 smaller—i.e., 1,152 smaller than $\frac{3}{114} = \frac{3}{114} \div 1152 = \frac{1}{43776}$, or nearly 1-44000th. I see the sun is now 32min. in diam.; this makes 1-41000th, instead of 1-44000th.

By the system of miniatures I have seen dark objects on a darkish background of a size immensely less than 1-100000th thick. A most useful formula for ascertaining size of miniature at a given distance ($d$) of an object with a lens of focus ($f$) is given by me in *Phil. Tr.*, Vol. II. 1870. If $m$ be the proportion of miniature to object, for a long distance $d$, from object to image nearly—

$$m = \frac{d}{f}.$$

In the case of ⅛th and half a mile distance, the rung of a ladder 1in. thick was beautifully seen—

$$m = \frac{\frac{1}{2}\text{ mile}}{\frac{1}{8}} = 31680 \times 8 = 253440 \text{ times.}$$

The rung of the ladder in the microscope was about the 250000th of an inch. With magnifying power of 1,000 diameters—all immersion lenses, set to "uncovered," with either water or glycerine between their noses, and sometimes a piece of cover glass ·004 thick. But without miniaturing at all, I have on several occasions exhibited, under peculiar conditions of illumination, jet-black dark bodies very much less than two millionths of an inch in size.

If you can dismiss diffraction, it is difficult to assign what really is the limit of visibility with absolutely perfect instrumentation. There is reason to believe from the markings on insects that minutiæ are visible to their eyes far more minute than anything our best microscopes accomplish. Now, what is the angle at which a bullet mark at 500 yards is seen? The mark is about an inch spot. The angle $= \frac{1}{500 \times 36} = \frac{1}{18000} = 19$ seconds of arc. (I have seen a rifleman mark down without a glass his own hits at this distance.)

Now, what would be the angle of vision subtended by the 1-100000th of an inch seen at 10in.? The angle (say $\theta$) $= \frac{1}{100000} \div 10 = \frac{1}{1000000} = \theta$. Now, a second is $\frac{1}{206000}$th, say, $\frac{1}{200000}$th. Hence this angle $\theta$ = one-fifth of a second. Now, if we could magnify this a thousand times—

$$1000 \times \theta = \tfrac{1}{5} \times 1000 \text{ secs.} = 200 \text{ seconds.}$$

So, after all, the size of a line $\frac{1}{100000}$ thick then presents a visual angle of 200 seconds; and yet 2 seconds has been authoritatively pronounced as the limiting angle of human vision! And the one-millionth of an inch would still present an angle of 20 secs. ten times larger than the assigned limits.

*With proper precautions*, the limit of angular vision, or linear diameter, in my experience, lies beyond the one millionth of an inch with the best glasses and finest manipulation.

With a clear power of 2,000, one millionth would subtend an angle of 40 seconds (at 10 inches).

**G. W. Royston-Pigott.**

Hastings, March 2.

## PHOSPHORIC ACID IN MANURES.

[23948.]—I FANCY I saw recently an inquiry as to the best method of ascertaining the amount of phosphoric acid in fertilisers, and as the subject is of much importance to agriculturists all the world over, the following from the *Chemical News* may be of use to some of your readers:—

"1. The sample should be well intermixed and properly prepared, so that separate portions shall actually represent the substance under examination, without loss or gain of moisture.

"2. Water-soluble Phosphoric Acid.—Bring 2grm. on a filter; add a little water; let it run out before adding more water, and repeat this treatment cautiously until no phosphate is likely to precipitate in the filter. (The washings may show turbidity after passing the filter.) When the substance is nearly washed in this manner, it is transferred to a mortar and rubbed with a rubber-tipped pestle to a homogeneous paste (but not further pulverised), then returned to the filter, and washed with water until the washings no longer react acid with delicate test-paper. Mix the washings. Take an aliquot (usually corresponding to one-third or one-half of a gram of the substance), and determine phosphoric acid as under Total Phosphoric Acid.

"3. Citrate-insoluble Phosphoric Acid.—Wash the residue of the treatment with water into 150cc. flask with 100cc. of strictly neutral ammonium citrate solution of 1·09 density; shred and add the filter paper; cork the flask securely; place in a water bath with constant temperature of 65° C., and digest for thirty minutes with frequent shaking. Filter the warm solution quickly, and wash with water of ordinary temperature.

"Transfer the filter and its contents to a porcelain capsule. Ignite until the organic matter is destroyed; treat with 10 to 15cc. of fuming hydrochloric acid; digest over a low flame, until the phosphate is dissolved; dilute to 200cc.; mix; pass through a dry filter; take an aliquot, and determine phosphoric acid as under total.

"4. Total Phosphoric Acid.—Weigh 2grm. into a capsule, add and mix intimately with 4 to 7cc. of a nearly saturated solution of magnesium hydrate, dry; ignite gently; if necessary, moisten the residue with nitric acid and ignite again to destroy all organic matter; add to the residue 15 to 20cc. of fuming hydrochloric acid; digest at a gentle heat until all phosphates are dissolved; dilute to 200cc.; mix; pass through a dry filter; take 50cc. of filtrate; neutralise with ammonia; add about 15grms. dry ammonium nitrate, and to the hot solution, for every decigram of $P_2O_5$ that is present, 50cc. of molybdic solution. (Test the filtrate by renewed digestion and addition of more molybdic solution.)

"Dissolve the precipitate on the filter with ammonia and hot water, and wash into a beaker to a bulk of not more than 100cc. Nearly neutralise with hydrochloric acid; cool, and add magnesia mixture from a burette, slowly (one drop per second), and stirring vigorously. After 15 minutes add 30cc. of ammonia solution of density 0·96. Let stand several hours. (Two hours are usually enough.) Filter; wash with dilute ammonia; ignite intensely for 10 minutes, and weigh.

"5. Citrate-soluble Phosphoric Acid.—The sum of the water-soluble and citrate-insoluble subtracted from the total gives the citrate-soluble.

### Preparation of Reagents.

"1. To Prepare Ammonium Citrate Solution.—Mix 370grm. of commercial citric acid with 1,500cc. of water; nearly neutralise with crushed commercial carbonate of ammonia, 410grm.; heat to expel the carbonic acid; cool; add ammonia until until exactly neutral (testing for excess both of acid and alkali by aid of delicate red and blue litmus papers), and bring to volume of 2 litres. Dilute further until the density is 1·09 as tested by the balance or *accurate* specific-gravity spindle.

"2. To Prepare Solution of Magnesium Nitrate.—Dissolve 320grm. of 'calcined magnesia' in nitric acid, avoiding excess of the latter; then add a little "calcined magnesia" in excess and boil; filter from the excess of magnesia, ferric oxide, &c., and bring to volume of 2 litres.

"3. To Prepare Molybdic Solution.—Dissolve 100grm. of molybdic acid in 400grm., or 417cc. of ammonia of sp. gr. 0·96, and pour the solution thus obtained into 1,500grm. or 1,250cc. of nitric acid of sp. gr. 1·20. Keep the mixture in a warm place for several days or until a portion heated to 40° C. deposits no yellow precipitate of ammonium phospho-molybdate. Decant the solution from any sediment, and preserve in glass-stopped vessels.

"4. To Prepare Ammonium Nitrate Solution.—Dissolve 200grms. of commercial ammonium nitrate in water, and bring to a volume of 2 litres.

"5. To Prepare Magnesia Mixture.—Dissolve 22grm. of recently ignited 'calcined magnesia' in dilute hydrochloric acid, avoiding excess of the latter. Add a little 'calcined magnesia' in excess, and boil a few minutes to precipitate iron, alumina, and phosphoric acid; filter, add 280grm. of ammonium chloride, 700cc. of ammonia of sp. gr. 0·96, and water enough to make the volume of 2 litres. Instead of the solution of 22grm. of 'calcined magnesia,' 110grm. of crystallised magnesium chloride ($MgCl_2 6H_2O$) may be used.

"6. Dilute Ammonia for Washing.—One volume ammonia of sp. gr. 0·96 mixed with 3 volumes of water, or, usually, 1 volume of concentrated ammonia with 6 volumes of water."

**F. I. C.**

## A FEW WORDS ON THE NEW TIME.

[23949.]—Whether or not the "new time" will ever become part and parcel of our everyday life is a matter of considerable uncertainty at present, and one which should be carefully considered before finally adopted. It is certainly a more scientific method of dividing the day than the present system of two periods of twelve hours each, and for that reason if for no other should be adopted if possible. It might with advantage be adopted by railway companies and the Telegraph and Postal Services. Railway and other time-tables would be much simpler and less liable to confuse one if the abbreviations a.m. and p.m. were rendered unnecessary. It would greatly facilitate its general adoption if the clocks in Government and other public buildings—e.g., railway stations, were made to indicate the new time; and if the time tables were altered as above suggested, the masses would very soon, from absolute necessity, be made familiar with the new style, and its general adoption would be almost certain. The feeling of novelty one would experience in, say, asking a friend to dine with them at eighteen o'clock, instead of saying 6 p.m., would, of course, soon wear off, and though it would have a more pedantic sound, it would take barely longer to give expression to than the present nomenclature. For purely scientific purposes, such, for instance, as the registering of physical and meteorological phenomena, the proposed change is admirably adapted; though it is exceedingly doubtful, as pointed out by Prof. Newcomb in the January number of the *Monthly Notices* of the R.A.S., whether the advantages to be gained by astronomers are of sufficient importance to cause them to adopt it. The referring all observations to the Greenwich meridian might possibly be an advantage, though changing the commencement of the astronomical day from noon to midnight would probably not be so. Considering that the change is only adopted at Greenwich by way of experiment for twelve months, and may not finally be made use of at that institution for recording astronomical phenomena; and in all probability will not be universally adopted by astronomers, it is certainly premature to make use of it for that purpose as some of your astronomical correspondents have done, until some authoritative decision has been arrived at. In the mean time, all those correspondents who prefer the new time for recording their astronomical observations, should distinctly state that they have made that use of it, to prevent confusion being made between the day reckoned from noon and the day reckoned from midnight. **B. J. Hopkins.**

# REPLIES TO QUERIES.

⁂ *In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[55226.]—**Screw-Cutting.**—"Young Turner" could cut a pitch of four threads to the inch in his lathe by using a 20 and 40, or a 60 and 120. If he has a back speed, a 20, 60, 30, 80, or 30, 70, 35, 120, or 50, 60, 75, 20,—any of these would cut a ¼in. pitch screw in a lathe with a ½in. pitch leading screw.—DUMBARTON.

*[55226.]*—**Screw Cutting.**—If you mean the wheels I gave in my index to "Glover" are not large enough to gear in your lathe, you can double the first set, which will be 40 mandrel, and 80 on leading screw, with the largest intermediate wheel you can get in. For the second set, change the 35 for a 50, and the 70 for a 100. If these are of no use, please write again, and I will do my best to help you.—VALETTA.

[55323.]—**Musical Scale.**—On page 564 Mr. S. E. Hunt objects to my division of the diatonic scale, because he believes that it gives different values to the two semitone intervals. How he arrives at this conclusion is not very clear. If he will turn to the monochord scale shown on page 478, he will there find that the values of all the semitones are identical; but for perfect accuracy in calculating the ratios it is, of course, necessary that the decimal fractions be completed, and this Mr. Hunt may easily do by carrying out the process there described according to which the scale is constructed. Here I beg to apologise for and correct an error I have made in copying out the decimal figures of the fraction expressing the semitone interval:—Instead of $\frac{100}{105{\cdot}333}$ it ought to be $\frac{100}{105{\cdot}3497}$ &c. The simplest vulgar fraction equivalent to this is $\frac{243}{256}$. Perhaps the following statement of the diatonic scale may give a more definite idea of it than can be got from the unavoidably imperfect decimal figures given for the monochord:—

| C | D | E | F | G | A | B | C |
|---|---|---|---|---|---|---|---|
| 81 | 72 | 64 | $60\frac{3}{4}$ | 54 | 48 | $42\frac{2}{3}$ | $40\frac{1}{2}$ |

$\frac{8}{9}$ $\frac{8}{9}$ $\frac{243}{256}$ $\frac{8}{9}$ $\frac{8}{9}$ $\frac{8}{9}$ $\frac{243}{256}$

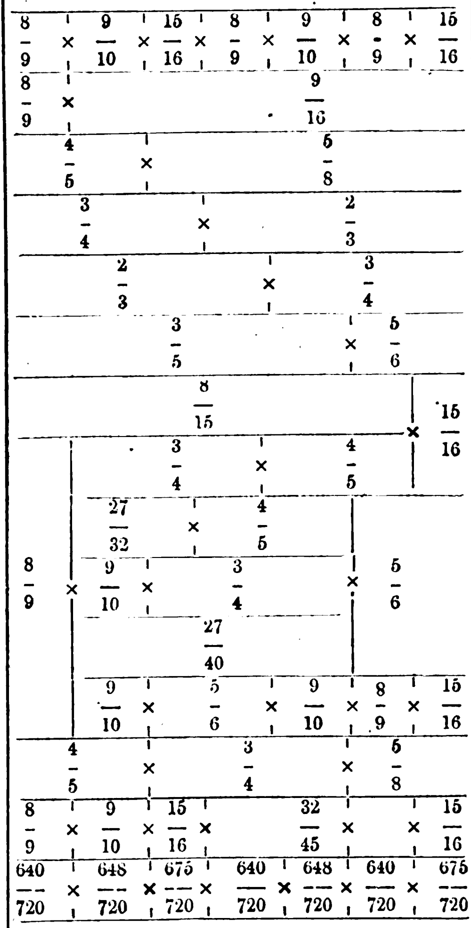
—WALTER HARDIE, Joppa.

[55323.]—**Musical Scale.**—In reply to Walter Hardie, in No. 1038, "E.M.," as an introduction, I would say in 1855 or 1856, I had "Hawkins' History of Music" lent me by a rev. gentleman. It was a reprint, I think, by Novello; in the preface is a catch which was copied from a "History by Dr. Burney," who was a contemporary; the catch was a satire on "Hawkins' History" by the words "Mystery and History: Burney's History and burn his history." Hawkins was a thorough mathematician as well as a musician; and Dr. Burney was not both; therefore, like many, if theory is spoken of, those who practise only, often ridicule, forgetting that others also can, and do, practise. Mathematical proportions of the monochord is the question now; and as my name has been called into it, I feel I must try to prove it. I will try another form to make what I think is correct. I will take only the major scale in the key of C, or I might trespass on time and space, and others might handle the question better. The fractions $\frac{8}{9}$, $\frac{3}{4}$, $\frac{2}{3}$, and $\frac{1}{2}$, are acknowledged; but $\frac{9}{10}$ and $\frac{15}{16}$ are not kindly received. I will leave out heights of bridges, frets, or shortening of strings by pressure, &c., and stick to the mathematical part of it.

MONOCHORD PROPORTIONS.

| | | | | | | | |
|---|---|---|---|---|---|---|---|
| 1 | $\frac{8}{9}$ | $\frac{4}{5}$ | $\frac{3}{4}$ | $\frac{2}{3}$ | $\frac{3}{5}$ | $\frac{8}{15}$ | $\frac{1}{2}$ |
| C | D | E | F | G | A | B | C |

INTERVALS.



| | | | | | | | |
|---|---|---|---|---|---|---|---|
| Monochord | 1 | | | | | | |
| Seconds | $\frac{8}{9}$ | $\frac{9}{10}$ | $\frac{15}{16}$ | | | | |
| Thirds | $\frac{4}{5}$ | $\frac{5}{6}$ | | to DF | $\frac{27}{32}$ | | |
| Fourths | $\frac{3}{4}$ | | | F to B | $\frac{32}{45}$ | AD | $\frac{20}{27}$ |
| Fifths | $\frac{2}{3}$ | | | DA | $\frac{27}{40}$ | BF | $\frac{135}{172}$ |
| Sixths | $\frac{3}{5}$ | $\frac{5}{8}$ | | FD | $\frac{16}{27}$ | | |
| Sevenths | $\frac{8}{15}$ | $\frac{9}{16}$ | | ED | $\frac{5}{9}$ | | |
| Octave | $\frac{1}{2}$ | | | | | | |

By taking the fractions as above, the whole of the monochord as 1 or any length of string, tuned to C, $\frac{8}{9}$ of this gives D—$\frac{9}{10}$ of D, or $\frac{8}{9} \times \frac{9}{10} = \frac{72}{90} = \frac{4}{5}$, or E $\times \frac{4}{5} \times \frac{15}{16} = \frac{60}{80} = \frac{3}{4}$, or F $\frac{3}{4} \times \frac{8}{9} = \frac{24}{36} = \frac{2}{3}$ or G—$\frac{2}{3} \times \frac{9}{10} = \frac{18}{30} = \frac{3}{5}$ or A—$\frac{3}{5} \times \frac{8}{9} = \frac{24}{45} = \frac{8}{15}$ or B—$\frac{8}{15} \times \frac{15}{16} = \frac{120}{240} \times \frac{1}{2}$ or C, the octave above the whole monochord note. The reason that these proportions are not generally received seems to be that all fifths have been taken alike—C to G, F to C, E to B. G to $\frac{4}{9}$ D, and A to $\frac{2}{5}$ E are perfect fifths, because in each, by taking the monochord fractions for the lowest note, and multiplying by the interval fractions, it will give the monochord fractions of a perfect fifth in each case; or, by taking the interval fractions and multiplying, we get the $\frac{2}{3}$ or fifth fraction; but from D to A it is not so, for this fifth is only $\frac{27}{40}$, therefore a smaller fifth. There is also another, the diminished fifth from B to F. The table above will show thirds, fourths, sixths, and sevenths of more than one fraction. I might go on, as I have done years ago, and show the difference of the additional flats and sharps which might be called into use to modulate into other keys; but the equal temperament has come into use, and more practical with all its shortcomings. I love to find the whys and wherefores of any question; but let us reason: we cannot square the circle, however near we get to it. I knew one man who worked that up to 200 decimals, and then he said he felt he might still go on. Messrs. Grey, "F. T.," and N. E. Child have already given enough to my mind; but there have been times when some slight difference has cleared a fog from my mind. I hope in this I have helped to do so to you. This theory I have put in practice, tested it, and found it agree—it coming to concords or discords by melody or "thorough bass," as the theory pointed out. This I tested by the family of instruments that might be called overblown pipes, such as the trombone, trumpet, French horn, Kent bugle, cornet, and other valve instruments; therefore, I feel I may write.—W. H. ELPHICK, New Cross, S. E.

[55384.]—**American Organ.**—In reply to "H. M. I. R." about shorter scale reeds (p. 15), I would point out to him that the manufacturers of reeds will make them of any scale desired, provided the order is sufficiently large: they will also make them to any pattern. The reeds used in the majority of organettes are of a smaller scale than those he mentions, and perhaps they may be on sale in this country; but certainly he can procure such special reeds as those used for the Euphone stop of one maker, and the Æoline and Vox humana of another. This fact induces me to make one more effort to clear up the extraordinary illusion about 8ft. reeds in 16ft. tubes. Tubeboards, I need scarcely remind your readers, are made by machinery, and it is necessary to fix upon dimensions and keep to them. The dimensions in use for ordinary registers of 8ft. and 4ft. have been adopted after experiment, and good results having been obtained, nothing more was desired; but it does not follow that no other dimensions could be used with the same reeds. As a matter of fact within the cognisance of anyone who has had much experience with reed organs, reeds which are said to be adapted only to certain tubes are found in tubes of all sorts of sizes: that is one of the means adopted to obtain variety of tone in large organs. It is very rare to find large reeds put into small tubes, because there is then a difficulty in fitting the "mute"; but reeds are often completely buried in tubes, the makers of the instruments being happily ignorant of the importance of studying that mysterious "windway."—FLIEGEN.

[55384.]—**American Organ.**—I have no wish to enter into any useless controversy with Mr. Floyd (p. 564); but I should like to correct his misconception with regard to "theoretical notions" to which he alludes. It is no mere "theoretical notion" to state that 8ft. reeds (as well as 16ft. and 4ft. reeds) should be placed in the cavities or tubes intended for them, for under these conditions the reeds give out the best results, if in other respects everything is all right. There is not the slightest necessity at any time of placing 8ft. reeds in cavities unsuited (without some alteration) for them. I think it but fair and just to remark that the explanation on p. 522 is clear enough on this point to any reasonable person. If any of "ours" see fit to place 8ft. reeds in tubes suitable for 16ft. reeds, I have nothing particular to say against it, except that there is no advantage whatever in adopting such a plan. Neither is it absolutely necessary in one single instance to resort to such a proceeding, and it is quite evident to all who understand the use of reeds that such a proceeding or undertaking as the one in question is in one or two respects objectionable. It would occupy too much space in "Ours" to fully explain what these objections are. I have pointed out one objection, and that must suffice. One thing is quite certain, and a fact that cannot be denied, and that is that no American-organ builder of repute was ever guilty of advising an amateur to place 8ft. reeds in tubes intended for 16ft. reeds. If, in any instance, there was the slightest necessity of resorting to such a proceeding, I would say nothing; but there is no necessity of doing so. In American organs, as well as other musical instruments, there is a proper place for every portion of the action, including the reeds. To those who possess a really good American organ I would say, Don't interfere with the instrument, but let well alone, for it is impossible for any amateur to improve a really well-made American organ. If any of "Ours" possess an inferior instrument, I should not blame them in the least for trying to improve it in any way, providing they are really capable of making the improvement. I always regard it as a pleasure to assist such persons, in spite of the credit which have been conferred on me by one correspondent who never do, or never has, given any valuable assistance to any of "ours"; but who is ever ready to find fault with those who do.—G. Fryer.

[55393]—**Lathe.**—To C. Calvert.—The plan you suggest of driving grindstone from lathe shaft is very reasonable, and is one easily applied as regards small stones. I hope to have a further say on this later on.—Invicta.

[55487.]—**Hot-Air and Vapour Baths.**—Yes, a gas-burner, a charcoal brazier, or anything else, provided the head is outside, or there is free ventilation, supposing it is a bath-chamber. You mean a portable bath, I presume. Always have the head outside that, for the hot air often acts injuriously when breathed, as many have found by going to the ordinary Turkish baths.—Massage.

[55571.]—**Turbines.**—I am sorry to say I cannot answer the query of "E. F." I take it that the authorities had a reason for saying "provided the draft tube is placed perpendicularly," or were not aware of any attempts to work in the manner described by the querist. As, however, some of the correspondents are skilled in using water-power, I have no doubt he will get a satisfactory reply shortly.—Essar.

[55679.]—**Lever Watch (U.Q.)**—To adjust a watch to the same rate when first placed in a horizontal, and then in a vertical position, is a difficult operation. The rates in a vertical and horizontal position are made identical, or nearly so, by equalising the resistance that interferes with the motion of the balance in the two cases, and by taking advantage of the displacement of the centre of gravity of the balance spring, satisfactory results will be obtained in most cases by employing the following methods, either separately or two or more together, according to the results of experiments or the rates, the experience, and the judgment of the workman. 1. Flatten slightly the ends of balance pivots, so as to increase their radii of friction when the watch is lying flat; the friction will be greater. 2. Let the thickness of jewel hole be more than is absolutely necessary. 3. Reduce the balance pivot, of course changing the holes, as the resistance due to friction when the watch is vertical, increases rapidly with any increase in the dia. of pivots. 4. Let the bal. spring be accurately centred, or it must usually be so placed that the lateral pull tends to lift the balance when the watch is hanging vertical. 5. Replace the bal. spring by one that is longer or shorter of the same strength. 6. Set the escapement, so that the strongest impulse corresponds with the greatest resistance of the balance. 7. Replace the balance. A balance that is too heavy renders timing in position impossible. 8. Lastly, when these methods are inapplicable or insufficient, there only remains the common practice of setting the balance "out of poise." If there is a gain in the vertical position of the watch, slightly reduce the lower side of balance. The oscillations will increase in extent, and the watch will lose in the above position. The converse must be done in the opposite case. When the vibration exceeds a whole turn, the changes will be the reverse to those above. This fact must not be forgotten in regard to duplex and lever escapements, which may at first swing more than a turn, and subsequently less, according to the state of the oil.—Annie.

[55783.]—**Sag of Telegraph Wires.**—According to Culley, it has been ascertained that on a standard line of 20 poles to the mile, the difference in dip is 3in. between 54° and 25° F. The expansion of the iron wire is about 4·1in. per mile for every ten degrees of temperature. The subject is rather too complicated to explain at length here; but Culley gives formula and a table for calculating sag, strain, temperature, and span.—P. T. S.

[55786.]—**Legal.**—This question is much too complicated, as it depends on whether property is freehold or leasehold, how long the rights to the path have been in existence. At any rate, tenants have nothing to do with it: it is the owners of the property who must be consulted. The tenant has a voice in the matter if he holds on a lease; but from the statement that B. is afraid of losing his tenant, I presume the cottages are let only on the usual terms.—Limb o' th' Law.

[55793.]—**Boiler.**—Querist does not give grate area. For multitubular boilers, the following is the formula—

$$H.P. = 1{\cdot}8\sqrt{S \times G},$$

where G equal area of grate in feet, and S equal the heating surface in yards. About 4½ square feet of heating surface is reckoned as a horse-power in multitubulars; but the best rule is to see how much water the boiler evaporates: 30lb., or half a cubic foot, should develop an I.H.P. with a moderately good engine.—Essar.

[55791.]—**Horizontal Engine.**—This is rather a peculiar query. Surely the length of the eccentric rod does not vary with the position of the slide-valve? What is it you wish to know?—Essar.

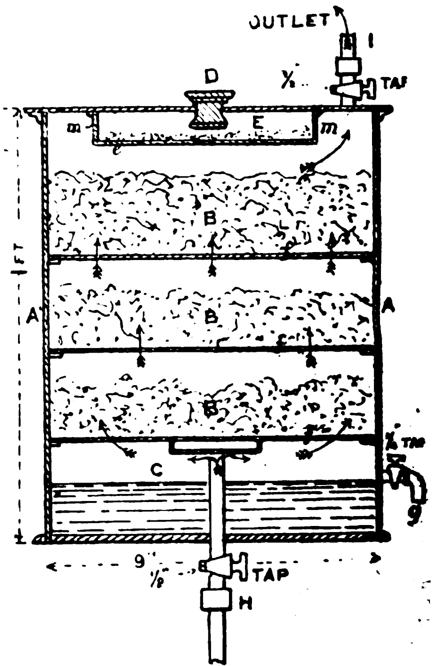
[55827.]—**Gravity and Dead Escapements.**—As Sir E. Beckett denies that I have quoted his book correctly, perhaps I may be allowed to give the words as they stand. At page 127 we read: "They (gravity escapements) are made by Mr. Brock, and I dare say by other makers, for half the price of the old-fashioned best dead-beat escapement regulators." The above, without doubt, conveys a wrong impression; for the comparative costliness of gravity regulators is a well known fact, and is referred to by Mr. Britten as such in the extract I gave last week, and also by "F.R.A.S." in his letter of the same date; and it is necessitated by the fact that clockmakers, both professional and amateur, have long since found out that gravity regulators must, in order to bring them up to the level of the dead beat, combine the very finest workmanship with a highly-numbered train. Sir E. Beckett, in his book, seems to me to lead one to suppose rather the opposite. On page 125, while admitting that the train should be a thoroughly good one, he says, "a highly-numbered train ought not to be requisite for these clocks," and also that the numbers "need not be anything like what are used for first-rate dead escapements." If Sir E. Beckett still holds this opinion, he does so, I believe, in opposition to that of all practical clockmakers. As Sir E. Beckett meets with a flat denial my statement that he does not seem sufficiently to recognise in his book those points mentioned by Mr. Britten, perhaps he will be so kind as to refer us to the page where such a recognition may be found. The sense in which I used the word "suitability" was, I think, sufficiently obvious, as having reference to cost and other considerations mentioned by Mr. Britten; and from this point of view it cannot, I think, be said that the G. escapement, as applied to regulators, is an "all-round" improvement on the dead-beat. Whatever difference of opinion there may be on this point, the fact remains that there is practically no demand for gravity regulators, and the dead-beat, as an escapement for regulators, holds its own, and is likely to continue to do so.—A Country Parson.

[55870.]—**Optics with the Lantern.**—I can find plenty of blow-through jets which will push up close enough to condensers to get a parallel beam. But I may say that if the condensers are at all short in focus, which is in itself desirable, blow-throughs are very dangerous to the glass, and parallel beam work with such jets is apt to be expensive. "S." will get much better results every way with a mixed jet, and with far less of this danger. Since his last letter I have made a special trial with the prism on "S.'s" account, with the comparatively feeble light of my Silber argand; but the only result is that I stand nonplussed at his difficulty. There is not so very much difference in brightness wherever a prism is placed, so long as a fair proportion of the cone of rays gets through it. The eye seems unable to distinguish beyond a certain extent. On the other hand, I find just beyond the crossing-point (not exactly *at*, but near, on one side or the other, and preferably on the screen side) is decidedly the best place, whatever light is used. "S." must somehow place his prism wrongly to the rays. Perhaps he is not careful to find the position of "least deviation," which is always the proper one, and is found by turning prism on its axis till the spectrum comes nearest to the direct image of the slit. No screen round the prism is ever needed when it is properly placed and used. I tried 5in., 7in., and 14in. focussing lenses—all the same result. A cylindrical lens is no use for any ordinary experiments, in all which the eye perceives no gain in brilliancy—a thing I do not quite understand. But to brighten faint spectra I use a cylindrical lens of about 5in. focus in the slide-stage of the optical front, and substitute an adjustable slit for the focussing power in the jacket, so that it can be brought to the focus of the cylindrical lens. By a "longer jet" I simply meant one longer from tray-pin to lime-pin: hence, a longer one, in any position of the tray, will place the lime nearer the condensers.—Lewis Wright.

[55870.]—**Optics with the Lantern.**—I have experienced the same difficulty as "S.," and have got out of the difficulty by putting aside my lime burner and gallery and constructing one on a very simple plan. If "S." would be willing and able to construct one, I will send drawings and instructions with pleasure. I can get my lime (cylinder) within an inch of condenser.—Excelsior.

[55870.]—**Optics with the Lantern.**—I get a parallel beam when the principal tube-jet is ½in. from condenser, and occasionally get a back lens fractured by the heat. It is impracticable and unnecessary to get nearer than this. The tubes of my jet were too short for this adjustment to be made until the condenser was brought back by means of metal collar. I strongly recommend "S." to get Lewis Wright's book on "Light," which I have found of great value. It has enabled me in a short time to emerge from the status of a blunderer to that of a somewhat expert demonstrator. I take the opportunity of mentioning a recent experience. In the slide stages of biunial I had a blue and a yellow solution for blending into white light. On removing these solutions the colours remained on the screen, and by experiment I found that the objectives had become transparent to these two colours, and opaque to the rest. Is this a usual experience?—W. H. Shrubsole.

[55876.]—**Improving Light in Coal-gas.**—In reply to "Woolwich Gas," I now send pen-and-ink sketch of a very good carburetter, which will give splendid results if followed in all details, each being requisite for the proper working of apparatus. This is made for using "benzol" or "benzoline," as this is preferable to all others for many reasons, a few of which I will give. Pure benzol is composed nearly all of benzene, and is the body lost to gas in carbonisation, being carried away in the residual tar, and it has been most successfully reproduced in the redistillation of the body. The wonderful influence of benzol when reunited to coal-gas in the carburetter may be evidenced by seeing the constituents of this body. It is as follows:—Benzene, $C_6H_6$; toluene, $C_7H_8$; xylene, $C_8H_{10}$; isoxylene, $C_8H_{10}$; pseudo-cumene, $C_9H_{12}$; mesitylene, $C_9H_{12}$; tetra-methyl benzene, $C_{10}H_{14}$. This is the rational formula of benzol, and these are the gases (if I may say so) that are lost in gas manufacture to a great degree. Mansfield found this out, and attempted to reproduce from the coal-tar spirit benzol for carburetting purposes; but chemistry was not sufficiently advanced at the period. I may say here you must be careful that all joints are well made, and that the lid, taps, screw-plug, &c., are all well soldered on, and the whole a sealed chamber, which need never be undone if all interior parts are properly joined and fixed, the benzol being very volatile and inflammable. No danger attaches to its use, however, if proper precautions are taken to keep a light from the spirit, and the taps turned off when not using, and a leather washer should be put under the thumb-screw, D. Explanation of sketch—A A is body of carburetter in section. This can either be round or square; but round is preferable, as less joints are required. It may be in measurement for from 10 to 20 lights—say, 9in. dia. and 12in. deep. The size you name is simply useless, and would give no result worth your trouble. It should be made of good stout tin, carefully jointed. B B, chambers partly filled with cotton wool. Don't use "sponge," as the cotton wool presents a far better surface to the rising gases, and if properly scattered will also act as a "governor" for the gas, keeping your lights from roaring or flickering when extra pressure is put on unknown to you at the works. C, chamber for benzol overplus of what the wool does not absorb; any overflow from this being taken off



at *g* tap, so that none may enter pipe H, over which I place a bit of tin to prevent any spirit running direct from chamber above it. D is the thumb-screw through which benzol is poured into carburetter, while E is a chamber made of fine wire gauze, marked $e^1$, on which a bit of wool is placed to scatter the spirit on chamber below. Gauze is soldered to lid at *m m*; *f f f* are partitions of perforated zinc, through which is found an easy gasway. These are fastened to the sides of vessel here and there, or may have supports tinned on sides for them to rest upon. By putting at least three trays of wool, there is a larger surface for the gas to take up spirit, and this will in turn be seen by the vastly improved light given. Always open tap *g* when you are putting spirit in at D, so that all overplus is returned to stock, and stock should be kept in a stoppered bottle. You will oblige me if, after you have tried this plan, you will send results to "ours," so that others suffering from poor gaslight (and these are numerous) may have the benefit of your observations.—Arvonia.

[55881.] — **Bar Armature.** — To Mr. S. Bottone.—I thank you very much for your kind inquiries; the mistake is mine. I should have mentioned that I wish to make an armature of copper bars, and use it instead of the Gramme ring. I wish to increase its efficiency. Could I get the required number of revs. from a ¼ h.p. gas-engine?—Amateur.

[55887.]—**Altering Clock.**—The reply to this query on page 16 is incorrect, for the arrngement, as illustrated and described, would not work. The design shown on page 567 is substantially correct, but is objectionable, on account of the pinion C riding upon the escape-wheel arbor, for this creates pressure, and consequently friction, between the pinion and the arbor, and destroys that perfect uniformity of driving force on the escape-wheel, which it is the great object of this remontoire arrangement to attain. If the escape-wheel arbor be mounted as shown on page 16, or in any similar way embodying the same principle, then the only friction to which it is subject will be that of its own pivots in their bearings, and that caused by the pressure of the fly ends upon the arbor. To diminish the former make the pivots as small in diameter as consistent with strength, and harden and polish them well, and to diminish the latter remove the piece D shown on page 567, and attach to each end of the fly projecting therefrom about ¾in., a steel wire about $\frac{1}{16}$in. square, or a round wire flattened at the end will do equally well. The *fly must be* sufficiently long to allow the wires to reach very nearly to the centre (not the circumference) of the escape-wheel arbor. Now on opposite sides of the said arbor and distant from each other along the arbor about ¾in. or so, cut with the edge of a flat file two nicks about ⅛in. or so wide, and deep enough to come to the centre of the arbor. It is clear that if the wires on fly are set in different planes the same distance apart as are the two nicks, they will alternately escape through them at every half-revolution of the arbor. The wires should be carefully shaped so as to minimise the friction and insure a prompt escape at the 30th second, and the arbor should be of small diameter, say, not more than ⅛in. where the nicks are, in order to reduce the radius with which the friction acts, and it and the wires should be hardened and polished in the acting parts. Of course, the further the wires are from their centre of motion—i.e., the fly arbor, the less will be their pressure upon the escape-wheel arbor. The diameter of the wheel G determines the maximum radius of the fly and wires. If the details of the existing clock are such that the above instructions cannot be exactly carried out, it will probably be easy to design another arrangement based upon the same principles. Some simple arrangement should be made by which the pressure of the spring can be adjusted so as to give the right amount of driving-force to the escape-wheel. I should strongly advise "Clockey" to fit this remontoire action to his clock, and if the escapement be well made and the pendulum a good one, accurately and firmly suspended, he will obtain such a highly satisfactory and accurate performance of the clock as will fully repay him for any trouble and expense incurred in making the alteration.—Wm. Granger.

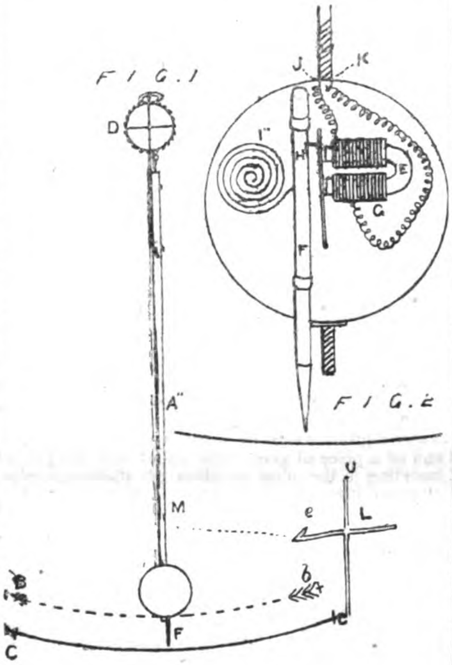
[55930.]—**Watch Winding.**—I do not quite understand from the description given, so should be glad if "Annie" would send the promised sketch.—M.M.I.Sc.S.

[55935.]—**Electro-Chemical.**—In reply to Mr. W. Grey *re* "several million volts," &c., I obtained the current from an induction coil giving 26in. sparks at the rate of 32,000 per minute, and absorbed about 30 h.p. for exciting the primary. This, I must add, was a *tour de force*, and could be kept up only for a short time. It was a discovery of my own, and a paper was read on the subject before the Royal Society in 1880 giving a detailed account of the results of this enormous and truly terrible current, in connection with my electric valve. I am writing an exhaustive account of these experiments and their results, which will shortly be in the press, and I must be pardoned for withholding any particulars which would anticipate such a work.—P. Ward.

[55935.]—**Electro-Chemical.** — Erratum.—34in. in this reply, page 16, should be 3 or 4.—Wm. John Grey, F.C.S., Gateshead-on-Tyne.

[55947.] — **Pressure of Water in Pipes.**—I think the following method of calculating the pressure of water in pipes at various depths will suit "One in a Fix": $\frac{\text{Head of water in feet} \times 62\frac{1}{2}}{144}$ = pressure in pounds per square inch. In answer to the second question let P = pressure in feet, *d* diameter of pipe, *l* length of pipe, and *v* velocity at point of issue in feet per minute; then $v = 2837{\cdot}5 \sqrt{\frac{P d}{l}}$, and $525\, v \times {\cdot}7854\, d^2$ = gallons of water per minute. The latter rule is given as for boreholes, but for practical purposes it may answer for "One in a Fix."—G. Worlands.

[55957.]—**Stop Watch.**—Does "Pendulum" want a portable instrument, or what? If not a portable one, I think the accompanying sketch will serve to show my idea. It is also the cheapest; I think it could be put in working order for a few shillings. A, Fig. 1, is the pendulum of an ordinary clock with long case. B *b* show the oscillation of same. Under the imaginary arc, B B, construct a piece of zinc or wood, C C, at equal distance from the pendulum. Now look at Fig. 2, which shows the pendulum on an enlarged scale; E is an electro-magnet, which liberates the metallic pencil, F, at the groove, H, immediately a current is put on; I is a strong spring to give the pencil a quick fall on its liberation; G shows coils on magnets. I and K are the two line wires, which should be insulated with silk, and carried up the pendulum to the arm; thence one to battery viâ bell push and one directly. It would also answer if the bell push was on the side of the clock (or where convenient). Its action will now plainly be seen. It is, as before said, an ordinary clock, and the seconds can be read by the dial. Now for the fractions. It is generally that the pendulum makes one oscillation per second; then the arc C C represents a second. The moment the spring push is pushed in the circuit is complete, and consequently the metallic pencil, F, drops, aided by the spring, I, and marks a piece of paper placed on the arc, C C, and stops the clock; then you divide off on paper with vernier or measure, and can arrive at the most accurate measurements of time. To know which way the pendulum has come, I should advise that it be started—say, from left to right for odd beats, and vice versâ for even beats. Example.—Clock stopped at five seconds, and pendulum marks precisely in centre of arc, C C. You know that the pendulum has come from right hand, for 5 is an odd number, and it has registered its last odd number, and is on the way to the even side. A good way is to put a piece of carbon paper over the ordinary paper, when the pencil leaves a clear, distinct mark. To start the pendulum off, a catch is provided at side of clock, see L *e* M. N is casing of clock. I hope this is what you want. If not, say more fully, and for what purpose.—Englethwaite.



[55972.]—**Glass Working.**—The kind of lamp used when gas is not obtainable is a long flat wick one, the length of the wick put parallel with blast from nozzle and fed with tallow. A metal shield is put over flame to protect it from draughts. Stick to your gas, it is far preferable to the old wick and fat. Any flame will turn lead glass black if the glass be put in the "reducing" part of it. "New Subscriber" had better use "soft Bohemian" glass until he gets expert enough to use the oxidising flame only.—P. Ward.

[55975.]—**Magnetism, 1881.**—Let A be the required angle, and let $T_1$ and $T_2$ be the moments of torsion round the centre required to deflect the 3in. and 5in. magnets respectively through 10°; let H represent the horizontal component of the earth's attraction, and *m* the amount of magnetism in each of the poles. Now since the magnet has two poles, the earth will act on both, and—

$$T_1 = 2\,m\,H\,\tfrac{3}{2}\ \text{sin.}\ 10^\circ$$
$$T_2 = 2\,m\,H\,\tfrac{5}{2}\ \text{sin.}\ 10$$

And since the angles of torsion are proportional to the moments—

$$\frac{180^\circ}{A} = \frac{T_1}{T_2} = \frac{3}{5}$$
$$\therefore 3\,A = 5 \times 180^\circ$$
$$\therefore A = 300^\circ$$

—$H_2S$.

[55978.]—**Tallow in Boilers.**—It is a most dangerous and ruinous practice to put any kind of oil or tallow in steam boilers, as in time it causes small pits like small-pox marks to be eaten into the plates. That is the reason why exhaust steam should never be turned direct into the feed water to heat it, as it always is laden more or less with particles of the lubricant.—P. Ward.

[55980.]—**Electric Bells.**—The galvanometer, or, more properly, galvanoscope, will not show where the fault lies, but only indicate whether a current is passing through it or not. There is no book published that would give you the information you want, as everything depends upon the circumstances of the case. If you will state the particulars of one breakdown you require put right, you shall have assistance to enable you to proceed, and that will give you much better information than could be derived by explaining away a supposition.—C. D R.

[55982.]—**The Zinc-Iron Cell.**—This cell only gives a powerful current at first starting, rapidly falling to nothing. If writers of books would test for themselves, and not accept unproved assertions, these errors would not find their way into print.—C. D. R.

[55983.]—**E. M. F.**—One way to get at E. M. F. of alternating current machine is to construct an instrument like Siemens's dynamometer, only wound with fine wire, as a voltmeter, and put it in "shunt." Of course, the constant of the instrument must be determined first.—P. Ward.

[55986.]—**Battery for Sewing - Machine Motor.**—Look up the indices; solutions for batteries have been given weekly almost. Do help yourself.—C. D. R.

[55987.]—**Zinc.**—Melt the zinc with the least possible heat; when melted put in a bit of sal-ammoniac and stir about till all the smoke has passed off, when all dross and impurities will have come to the surface; skim off carefully, and pour into cakes, which, when thoroughly cold, roll out into sheets; if it will not interfere with battery use, the addition of some grain tin would be an improvement.—Dens.

[55997.]—**Paint.**—It is the sun that does it, and it is very trying to withstand, and it is a well-known fact that the sun has more power on dark paint than it has on light paint; but if "Tram" will begin sooner, so that it can get well dry before the hot sun comes, and not put quite so much linseed oil in his paint, say, enough to make it about as thick as paste, and put sugar-of-lead driers, then thin with turps, and use nothing but the best, he will then get over it, as I have done many a time.—Calix.

[55997.]—**Paint.**—If the previous coats of paint are not taken off, but merely covered over with fresh, it will be certain to blister in the sun.—C. D. R.

[56001.] — **Ventilation of Colliery.** — It is almost impossible to answer this question so as to satisfy your correspondent without further information, as so much depends on other circumstances, besides depth and size of shafts. Waddle, Guibal, and Schiele are all good fans, whilst a more recent one, called the "Capel," is producing excellent results. If a "Mining Engineer" will advertise his address, I shall be most happy to assist him.—G. Worlands.

[56001.]—**Ventilation of Colliery.**—"Mining Engineer" will find the "Acme" patent system of ventilation the most compact, best, and cheapest, requiring but a fourth the power taken to drive a fan.—J. C. Baker, C.E., Liverpool.

[56008.]—**Bichromate Cell.**—Lead will answer perfectly for the containing cells of this battery. The chromic solution turns it yellow (forming chrome yellow I suppose); but does not further effect it. I have a plate by me which has been immersed for nearly six months. Lead will not, however, do for the negative surface, as in the Daniell's cell; but it is sometimes used as a support for a sheet of platinised platinum, which is very efficient.—G. JACKSON.

[56008.]—**Bichromate Cell.**—Yes, you can use lead for cells. See the description of the Edco battery, p. 379, No. 980, and subsequent numbers. —C. D. R.

[56010.]—**Milling Hose, &c.**—As it will depend upon the kind of goods to be treated, also the quantity requiring to be operated upon in a given time, say, a week, as also the amount of motive power at command, before any practical reply could be given to "G. B. P.'s" questions; so if "G. P. B." would put an address in the proper column of "Ours," I will send jotting.—X. Y.

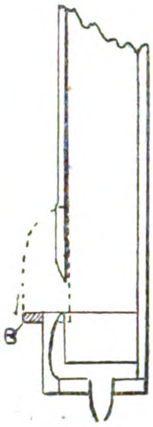
[56014.] — **Internal Gear Wheels.** — To "J. H."—Pitch of large wheel is $4\frac{7}{8}$in., with 48 teeth. Pitch of small wheel is $4\frac{1}{4}$in., with 44 teeth. Length of large wheel is $\frac{1}{4}$in. bare. The smaller wheel is the one I want to get out more exactly. I have got the wheels to work together, but they don't go quite smoothly. Should be obliged to "J. H." if he can give me rule for spacing and shape of teeth.—HYPO.

[56025.]—**Trueing Grindstone.**—All honour to "Marcus." There has latterly been a great tendency in "Ours" to get at trade secrets and the mode of getting round a patent. This is only evidence of the Socialistic tendency of the times. I may assist "Marcus's" statement by reminding your readers that the prohibition clause in the patent is against making, using, vending, or exercising the invention without the license of the patentee.—Z. Y. X.

[56025.] —**Trueing Grindstone.** — Being a patentee, I naturally agree with the remarks of "Marcus," and I am sure the general public share his views; but my experience has altered my views in this particular case; it is this:—These grindstone dressers were shown at the Health Exhibition, and I have been familiar with their use for years; but the attendant explained that they were preferable to the diamond for trueing emery-wheels. I therefore took their price list, giving price of cutters as 1s. 3d. each, resolving, when in Westminster, to get a cutter to try upon an old cutter-spindle. On calling at the office some time after, I was informed that they only sold the cutters to persons having their machines (the machine is a rough single slide-rest, with a cast cutter-spindle to swivel on the top, instead of fixing it under the tool-holder in the ordinary way). I said, in that case, I shall have to make one. I was told, with much high-handed bad feeling, that if I did they would prosecute me for fraud, and demanded my address, which I did not give. Such treatment I have not before received from business people. Next day I tried an ordinary pipe-cutter upon the spindle in the slide-rest; it cut up an emery-wheel very nicely. Later, having business at the Patent Office, I searched up the matter, and I found that the action of cutters revolving by contact had been known and used for 20 or 30 years for similar purposes, and that Brunton's patent, No. 702—1875, stated:—"I bring the stone to be operated upon into contact with rapidly revolving cutters"—the subject matter and drawings show the action to be that of communicating this rapid motion to the circular cutters "by means of toothed or friction wheels" (this action will be familiar to those who use the cutter-spindle); and he claims "imparting to cutting-discs a positive rotary motion on their own axis, independent of the rotation which they derive from the contact with the stone"; showing there was no attempt to claim the old method of cutters revolving by contact. Now, with grindstones and emery-wheels we do not drive the cutter, it turns by contact only. I again called and explained that they seemed to have no patent at all; they then said that they did not particularly claim the old method, but they now specially claimed the making of the cutter itself of a stamped cone of thin sheet steel, which keeps its edge to the last, recently patented. Evidently they try to what is vulgarly called *rush* those who go to buy what they advertise to sell in order that they may sell something else. It is the grocer who sells sugar only to those who buy tea. Without questioning the validity of a patent, I would not on principle make a thing patented by another unless he refused to sell it to me. I do not think the question of the validity of a patent is good subject for discussion in these pages, unless in public interest to expose such proceedings as these. "Marcus" is not aware of this system of business, as, I think, he and everyone else will uphold—FAIR DEALING IN MONOPOLY.

[56028.]—**Induction Coil.**—Under "Answers to Correspondents" you will find a list of back numbers, and amongst them Coils, induction, Nos. 832, 815. Send stamps to the Editor, with a request to forward by return, and proceed to make your coil from the instructions therein contained. It will save you a deal of trouble.—C. D. R.

[56029.]—**Organ – Voicing Pedal Open Diapason Pipes.**—The cause is probably the want of a "beard," which is a piece of wood (any thickness) placed directly under the mouth, outside, to prevent the too-great updraught interfering with the proper intonation of the pipe. The annexed sketch will explain. The required breadth of the beard for any of the pipes may be best ascertained by experiment, but I should say a couple of inches (at most) would suit your largest. "Ears" might be added with advantage, and would support the beard. The dotted line in the figure will show what I mean; they may be of light stuff and screwed to either side of the pipe.—HAM.



[56033.]—**Shocking Coil.**—You can regulate the strength by employing a water regulator, or putting the coil into a brass tube and withdrawing it gradually to intensify the current. A simple water regulator can be made by plugging up the end of a piece of glass tube about 9in. long, and inserting in the plug a piece of platinum wire, allowing it to protrude into the tube 1-16th of an inch, and leave sufficient outside to solder a copper wire. The other end must now be plugged in like manner, and into this a brass wire must be inserted tipped with platinum. The brass must be of sufficient length to allow it to slide down the tube and touch the platinum at the other end. If the tube be filled with water and stood upon end or supported in a rack, your regulator is complete. To use it, connect a wire from one of the binding screws of the coil to the platinum end, and from the sliding brass rod fasten the wire on which one of the handles is connected. Withdraw the rod from the tube to its utmost limit, and you have now the means of regulating the current by sliding the rod down the tube. You can, if you wish, mount the regulator with brass caps and wooden frame with binding screws.—C. D. R.

[56033.]—**Shocking Coil.** —Presuming your electro-magnet consists of a bundle of thin iron wires, or a solid piece of soft iron placed in the tube of your coil, you can regulate the shock, to a great extent, by cutting a brass tube the length of the core, which can slide freely in the central tube enclosing the iron bundle. You can regulate the shock by this brass tube, sliding it out and in as you want an increase or a decrease of shock. If the shock is too strong with the brass tube covering the entire length of the core, I should advise the use of a small bichromate cell, or fewer layers of secondary.—BOBADIL.

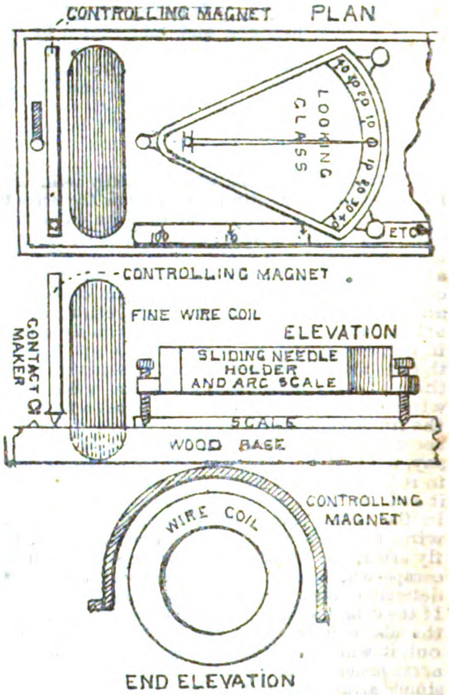
[56035.]—**Books on Veterinary Medicine.** —In my opinion the following are the best:—Williams' "Principles and Practice of Veterinary Medicine"; ditto, "Surgery"; Greswell's "Manual of Equine Medicine"; Robertson's "Equine Medicine." Pathology is best learnt from works on human pathology, such as "Green" or "Pepper."—GEO. A. WALTON.

[56037.] —**Induction Coil.** — Your wooden bobbin may be too thick in the tube; but whether or not, you must make a fresh cone. Why did you not make it of cotton wool at once? Take out the lemonade-bottle wire, and insert a core made of soft iron wires, No. 16 B.W.G. If you cannot procure it, use a piece of round iron rod of the size required. You do not want a condenser for giving shocks; nor anything like so much secondary. I presume you have fitted a contact breaker?—C. D. R.

[56037.]—**Induction Coil.** — Your secondary wire is too thick. Better to have used a size between Nos. 35 and 40, silk-covered. Every layer must be thoroughly insulated. If not, the coil fails. You do not require condenser for shocking purposes; but if for experiment proceed thus: —Prepare 50 or more sheets of tinfoil, each sheet 5in. long and 5in. wide, two thin boards of hard wood of a smaller size, and 60 sheets of thin paper steeped in paraffin wax, each 7 by 5. Upon one of the boards place five of the sheets of paper, and then one of the tinfoil sheets, placing the latter so that 1in. of its breadth projects over the side of the paper. Lay another paper on this, in the same position as the first, and upon this you place the second sheet of the tinfoil, but with the projecting part on the opposite side to that of the former one. Cover this with an insulating sheet, and lay down a third tinfoil sheet, with its projecting part on the same side as the first tinfoil. Arrange the other tinfoil sheets in similar order, remembering that ends of each alternate tinfoil sheet project at one side, and the ends of the intervening ones at the opposite side. Then lay on five more papers and the second board. Tie up the whole with a stout string, pressing together the projecting tinfoils at one side, and also those at the other side. You connect these two tinfoil projections, one to the spring and the other to the screw of the contact-breaker. The dimensions given may not suit your coil, as the size of condensers varies; but the best way to discover the size is to arrange as described, and connect temporarily to the coil, increasing battery power gradually to the strongest you are likely to use, and add sheet after sheet of tinfoil as long as beneficial effects are produced.—BOBADIL.

[56041.]—**Gun-Metal.**—As gun-metal is composed of copper and tin, copper and zinc, or those three metals with the addition of iron, it is not easy to understand in what proportions they can be mixed to withstand the action of a 3 per cent. solution of sulphuric acid. Does the queriest know of such an alloy?—NUN. DOR.

[56042.]—**Voltmeter.**—I reluctantly send sketch of Thompson's graded voltmeter in answer to "Volt's" second request for me to do so. I say reluctantly, because it is an imperfect sketch from memory, it being now over a year (through a lamentable personal accident) since I saw the instrument; but I think that the principle and general construction will be evident to him, especially if he looks up my description of it in a back number. —P. WARD.



[56043.] — **Engraving with Acid.** — I think "Acier" will find the following the most satisfactory process. First coat the surface to be etched upon with a thin film of yellow soap. Scratch out the lines of the pattern with a needle point; if the lines are to be broad, the point should be ground down a little. Then apply the following mixture: copper sulphate, 4 drachms; alum, 4 drachms; common salt, 4 drachms, with enough liquid acetic acid to dissolve the whole. If the article is large, as, for instance, a saw-blade, it will be sufficient to flood with the above solution, and leave for some time. If, however, the article is small, it is more convenient to plunge in mixture, and take out when required. The length of time for the steel to remain in the solution varies, of course, with the depth of lines required; but from five minutes to half an hour will generally suffice. If you have flooded the steel, it is best to remove the solution by means of blotting-paper before wiping off the soap.—Mikros.

[56045.]—**Lantern Lamps.**—I think "Exhibitor" will find what he requires in the numbers of your journal for January 16th and 23rd, 1885, under the head (55648) "Pamphengos Magic Lantern." He will also find some useful information in your journal for April 4th, 1884, page 100, by "Limelight," "On Mineral Oil Lamps for the Optical Lantern."—Syntax.

[56045.]—**Lantern Lamps.**—If "Exhibitor" really wishes for an appreciable increase of light, why not go in for limelight, which can be added at less cost than the 4-wick refulgent lamp if he can bring a small amount of ingenuity and patience to bear upon it? Should be glad to assist "Exhibitor" in this, also other correspondents who for an unexplained reason seem to be afraid of limelight being too expensive, when, in reality, it is not so.—Excelsior.

[56046.]—**Turning Spindle.**—If "Apprentice" will test his centres, he will no doubt find that they are not true. True up the centres, and turn them both to the same angle, and see that everything is clean when you reverse the spindle.—Valetta.

[56046.]—**Turning Spindle.**—The running centre cannot be true. If this is the case, turn it true with your graver. Were the centres punched in the spindle lopsided, causing it to run with a side bearing?—C. D. R.

[56046.]—**Turning Spindle.**—"Apprentice" will find that the point of his live centre describes a circle. True up the centre, but do not harden it. This will be sufficient if centre is at fault, but if mandrel nose is bent, mark centre and nose, and always insert former in same position. If mandrel nose is soft, it may be re-bored.—Geo. A. Walton.

[56051.]—**Gramme Dynamo Machine.**—If your query is worded correctly, the dynamo should have an E.M.F. of 120 volts, and a current of 300 ampères, and it will absorb between 60h.p. and 70h.p. If you have never made a dynamo before, a 600-light machine is no light matter. Send full particulars as to diameter of ring, length, breadth, and width of magnet-core, and also the width of the pole pieces. Through not sending full particulars, a querist ("Anglo-Dane") is making a dynamo, which, in my opinion, when it is finished, will stand a good chance of being thrown on the scrap heap. Perhaps, by 600-light, you mean 600 candle-power? *If* so, the matter is greatly simplified.—*W. H. Eaves*, Coventry.

[56052.]—**Kerosene Lamp.**—If kerosene oil is good, it will not burn without a wick unless heated considerably. Let "Brickwall" fill a cup with kerosene and plunge a lighted match into it so as to immerse the lighted part, the match will be put out. But when a lamp is thrown down the lighted wick often comes in contact with the spilt oil, and then the carpet or tablecloth becomes an enormous wick. The best extinguisher would be damp sand, but, of course, this is not always handy. Water is not to be despised, however, and is usually to be had at a moment's notice. A rug or large cloth is a good extinguisher if thrown over all the flame, and this, combined with water, ought always to be efficient if applied promptly.—Geo. A. Walton.

[56053.]—**Singing Noises in the Head.**—It is difficult to answer medical queries without examining the case, and I would earnestly advise "Arvonia" to consult his medical man. If he obtains no relief, he can consult a specialist. In questions involving medical aid the rich man has no advantage over the poor, for the latter may have the best opinion on his case at institutions for that purpose. It may be that "Arvonia's" trouble is caused by wax in the ears (a common cause); but this he cannot remove himself, and I would warn him not to be disappointed if he relies upon advice, which I expect he will get through these columns, recommending onions for breakfast, carrots for dinner, and parsley for tea, or some other such nonsense.—Geo. A. Walton.

[56059.]—**Geneva Watch.**—The cause of stopping is easily detected by the fact of it going while being "still," and "Ll. B. A." should first examine the hair spring, which most likely is in contact when in certain positions; secondly, see if it is in beat—i.e., the cylinder must be at right angles to the tooth of 'scape when in the shell of cylinder, when not in action; thirdly, examine cock jewel hole and top stone: if a fracture in either, the watch will stop when held face downwards, and so with foot hole, vice versâ. See there is not too much "end shake" in cock, or too much in foot holes, which will cause the cylinder to shift up and down as the watch is moved, and strike 'scape teeth improperly. Is your motion work free? also hands?—F. Hunt, Widnes, Lancashire.

[56061.]—**Vapour Density.**—The observed volume of vapour must be corrected for the expansion of the tube containing it. Taking the cubical expansion of glass as ·0000262, then at a temperature of 215° the observed volume must be multiplied by—

$$1 + ({\cdot}0000262 \times 215) = 1{\cdot}00563.$$

This gives the real volume to be 51·056cm.$^3$ The 80mm. difference of height of mercury inside and outside the tube must next be corrected to zero, for which we have—

$$\text{True height} = 80 - (80 \times 215 \times {\cdot}0001815) = 76{\cdot}88\text{mm}.$$

The actual pressure on the vapour is, therefore—

$$755{\cdot}5 - 76{\cdot}88 + 16{\cdot}9 = 695{\cdot}52\text{mm}.$$

It is now necessary to ascertain what would be the volume of the vapour under standard conditions, and we evidently have—

$$v = \frac{273 \times 695{\cdot}52 \times 51{\cdot}0566}{488 \times 760} = 26{\cdot}139\text{cm.}^3$$

A litre will weigh

$$\frac{{\cdot}1163 \times 1000}{26{\cdot}139} = 4{\cdot}4493\text{grm.}$$

Dividing this by the weight of a litre of hydrogen—i.e., ·0896grm., we obtain the vapour density = 49·657.—Wm. John Grey, F.C.S., Gateshead-on-Tyne.

[56062.]—**Chemical Problems.**—·567grm. of $CO_2$ contains $\frac{{\cdot}567 \times 3}{11}$grm. of carbon. Hence, the percentage of C in the substance is—

$$= \frac{{\cdot}567 \times 3 \times 100}{{\cdot}4245 \times 11} = 36{\cdot}428$$

·3025grm. of $H_2O$ contains $\frac{{\cdot}3025}{9}$grm. of hydrogen. Hence the percentage of H in the substance is—

$$\frac{{\cdot}3025 \times 100}{{\cdot}4245 \times 9} = 7{\cdot}917.$$

Calculating the reduced silver to argentic chloride, we get ·4074grm. as the total weight thereof; and as 287grm. AgCl contain 71grm. Cl, we have for the quantity of chlorine

$$= \frac{{\cdot}4074 \times 71}{287}\text{grm.}$$

and the amount per cent. is—

$$\frac{{\cdot}4074 \times 71 \times 100}{{\cdot}181 \times 287} = 55{\cdot}682$$

Thus, the found conposition is—

| | |
|---|---|
| Chlorine | 55·682 |
| Carbon | 36·428 |
| Hydrogen | 7·917 |
| | 100·027 |

Dividing each of these by the atomic weight of its element, we get the numbers 1·57, 3·03, 7·91; and taking the lowest as unity, we obtain the coefficients—

$$Cl_1\, H_{5{\cdot}01}\, C_{1{\cdot}93}$$

Now, an organic combustion usually gives the carbon too low and the hydrogen too high, so we may take $C_2H_5Cl$ as the formula required. Calculating the percentage composition of this body we obtain—

| | |
|---|---|
| Chlorine | 55·03 |
| Carbon | 37·20 |
| Hydrogen | 7·75 |
| | 99·98 |

There is rather too much error in the carbon for a good combustion. The determination of the vapour density is as follows: Corrected difference of level of mercury—

$$= 140{\cdot}5 - (140{\cdot}5 \times 50 \times {\cdot}0001815) = 139{\cdot}225\text{mm.}$$

Corrected volume of vapour—

$$46{\cdot}2 \times [10 + (0000262 \times 50)] = 46{\cdot}26\text{cc.}$$

The difference of level of the oil is not given, so we cannot allow for it, and must take the effective pressure on the vapour to be—

$$739 - 139{\cdot}225 = 599{\cdot}775\text{mm.}$$

Correcting to standard conditions we obtain—

$$v = \frac{46{\cdot}26 \times 599{\cdot}775 \times 273}{760 \times 323} = 30{\cdot}856\text{cm.}^3$$

Hence a litre weights—

$$\frac{{\cdot}0803 \times 1000}{30{\cdot}856} = 2{\cdot}6024\text{grm.}$$

and dividing this by ·0896 we get the vapour density = 29·044. The theoretical vapour density of ethyl chloride is 32·25. The temperature of the air is not needed.—Wm. John Grey, F.C.S., Gateshead-on-Tyne.

[56064.]—**Troublesome Battery.**—You have very probably a leakage somewhere, causing the battery to be constantly at work. You say that it does principally bell-work? Do you use it for any purpose for which a constant current is required? If so, this will account for the state you complain of, as your description points to the fact that the cells have been worked to exhaustion. You must test the system and discover, if possible, whether any leakage occurs. It may be that one of the pushes is in slight contact. If so, this will account for your trouble. Test the battery, see that the connections are perfectly clean and dry, clean out the cells, thoroughly wash with hot water, put in fresh solution of sal-ammoniac, only half-saturated, made by dissolving the salt in water until it will take up no more, and diluting with the same quantity. Clean your zincs, and, if worn, put new ones in. The zincs should be as pure as possible, as if they contain, as they often do, impurities, a local action is set up within them, and they consume away.—C. D. R.

[56065.]—**Tricycle Spokes.**—I should not, if I were you, bother with the enamel; scour the spokes with emery-paper, getting off as much rust as possible; serve hubs the same; and then give it two coats of Japan varnish, which you may thin with some spirits of wine. If you can put the machine in a warm place to dry, you will get a nice glossy black, at a cost of about 3d.—W. H. Eaves, Coventry.

[56066.]—**Gas Purifier.**—If "J. B. C." will look for my reply to "Woolwich Gas" on this subject, which will, with the Editor's permission, appear either in this or following number, he will see something which will be adapted to his case, although not just as he has requested, as the Albo-Carbon burner is a patent, and also is so constituted as to always require heat to develop its energies and give the result to increase of light. If "J. B. C." follows the instructions given, closely, he will obtain excellent results. The apparatus should be put just beyond where the gas issues from meter.—Arvonia.

[56070.]—**G. E. Engines.**—I believe the 8-wheeled double-end tank engines already at work are numbered 650—659. They have been built by the G. E. Railway Company, at their works at Stratford, where more of the same type are in construction. Following Mr. Webb's practice, Mr. Worsdell has fitted them with radial axle-boxes at both ends.—B.

[56071.]—**L. and N. W. Railway Engines.**—I am not aware of any 6ft. engines having been made by Ramsbottom; but the following are the required dimensions of his 6ft. 7½in. 4-wheeled coupled engines:—Firebox, 4ft. 3in. long, 3ft. 6in. wide; area, 15 sq. ft.; 192 brass tubes 1⅛ diam.; heating-surface, 1,013 sq. ft.; and that of firebox is 89 sq. ft.; total heating-surface, 1,102 sq. ft., or 73½ times the grate area. With trains averaging ten carriages the consumption of coal is 26·3lb. per mile. All boiler plates are $\frac{13}{32}$ thick.

Distribution of Weight.

| | Tons. | Cwt. |
|---|---|---|
| Leading Wheels | 9 | 9 |
| Driving ,, | 11 | 0 |
| Trailing ,, | 8 | 16 |
| Total | 29 | 4 |

—Regulator.

[56076.]—**Rope Pulleys.**—It is just possible to get a motion at right angles with rope pulleys, but I would not say much for the rope after it had had a little wear.—Valetta.

[56077.]—**Specific Heat.**—A mass of 1lb. falling 1,390ft. evolves a unit of heat (theoretically) on striking the ground. The latent heat of water is 80 units; hence, the ice must fall 1390 × 80 = 111,200ft. = 21 miles to melt it. In order to evaporate it, there would be needed 80 + 100 + 540 = 720 units, so it would have to fall 720 × 1,390 = 1,000,800ft. = 189 miles. I answered this question (which is from Thorpe's book) about a year ago.—Wm. John Grey, F.C.S., Gateshead-on-Tyne.

The Prudential Assurance Company have just issued their thirty-sixth annual report, which shows that during the last twelve months the funds have increased by a sum of £862,000. Of this £158,840 is due to the Ordinary Branch, and £703,766 to the Industrial portion of the business. These additions raise the assets of the Company to the sum of £4,711,464. In the new business of the Ordinary Branch we find 11,823 policies, assuring a sum of £1,359,361, which produce an annual premium income of £58,580. The premiums of the year amount to £238,868, which is an increase over the year 1883 of no less a sum than £58,580. The number of policies now in force in this branch is 51,835. In the Industrial Branch during the year the premiums received have reached the sum of £2,644,516, an increase on the previous year of £140,208. The number of policies in the Industrial Branch show a total of 2,302,890. The expenditure shows a rate of reduction equal to 2 per cent. on the premium income.

The 18 in. gauge railway from Suakin to Berber, 4½ miles of which are already on the spot, will not be proceeded with.

# UNANSWERED QUERIES.

*The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered are repeated four weeks afterwards. We trust our readers will look over the list and send what information they can for the benefit of their fellow contributors.*

Since our last, "Annie" has replied to 55679.

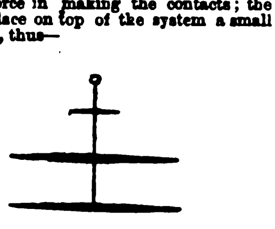
# QUERIES.

[56079.]—**Lathe**—I have a 3in. centre lathe, with good slide-rest. If I set rest right, for turning truly parallel between the centres, and then come to bore, or turn anything from mandrel alone, I find the hole, or work, is not parallel, notwithstanding that the lathe centres coincide when slid along the bed. I suppose it is because the mandrel is not truly parallel with bed of lathe. Will you kindly tell me the best way to adjust it, so as to turn truly parallel, whether between centres or from mandrel alone, without shifting quadrant of slide-rest? I may mention the rest is a bought one, the lathe home made, with parallel necks to mandrel, running in halved brasses. Would it be more reliable if I made brasses whole, and made a new steel mandrel, with cones to run in brasses, and could I bore brasses out after fitting in head, with present rest, not having another lathe to run to?—PRO BONO PUBLICO.

[56080.]—**Helical Teeth.**—To "J. H."—I should be very much obliged, and no doubt others, if "J. H." would give full particulars (with sketches, as I understand those better than technical terms) for striking out and making large wheels, say 5in. pitch, 12in. wide, and 60 teeth, by core box. I am conversant with ordinary gear, but don't understand when you part the teeth in core-box. With ordinary you part in centre of teeth—do you do the same with helical, which would mean ends to be at an angle,—in your reply to "Novice," No. 55745, when a pattern is made to joint through centre, and each half screwed out of mould; am I right? Also a helical tooth is simply a tooth with all the ordinary conditions of plain gear observed, but laid at an angle? Is there any difference in the space of teeth allowed—more, or the same? An early answer would be greatly appreciated.—ATHOS.

[56081.]—**Electrical.**—I am constructing an apparatus, in which, amongst other essential features the sounding of an electric bell, or any other form of alarm, by the deflection of the astatic needles of a common galvanometer, is a vital one. The needles are 1¼in. in length, and suspended. I have failed at present, owing to a want of force in making the contacts; the plan tried being to place on top of the system a small shaft of platinum wire, thus—



The sharp points of which were intended to prick two small globules of mercury, held in cups at the ends of the battery, and bell wires which were brought over the top of the instrument to meet them. There is an objection, however, to this plan, even if successful; as, in working, the mercury would be liable to be jerked out.—BAFFLED.

[56082.]—**Telephone Transmitter.**—Will Mr. Lancaster, or some other subscriber to the "E. M.," give a diagram, with dimensions, of a good telephone transmitter to fit in a box 4in. square, with induction coil? I think the Blake transmitter is the best. I use three No. 3 Leclanché cells at one end of line for telephone circuit; the distance between each instrument, say, ½ mile.—T.

[56083.]—**Telescope.**—Would Mr. Lancaster, or some other optical correspondent, inform me as to the arrangement of lenses (focal lengths, distances apart, and diaphragms) for terrestrial eyepieces of powers suitable for 1in. and 1½in., achro. o.g.'s? I am thinking of having two powers for the larger o.g.—one moderate, and one high; the latter for clear days. I should also like to know the best focal lengths for the two o.g.'s. I cannot refer to back numbers, as I am at a considerable distance from mine. An answer to the above will greatly oblige.—J. P.

[56084.]—**Canvas Canoe Building.**—Will some readers of "Ours" help me on the above subject? I want to build a small one, chiefly for sailing, to take yachting with me, and light enough to sling in davits inside another boat. The loan of working drawings would be very acceptable. Is there any book published on the subject?—CECIL D. TRAVERS-WIRE, Croom's Hill, S.E.

[56085.]—**Scroll Chuck.**—My scroll chuck has become difficult to work through becoming clogged by using inferior oil. Shall be thankful if any reader will kindly instruct me how to take it apart to clean it.—B.

[56086.]—**Optical Formula.**—To MR. BRADBURY.—I have recently come into possession of a copy of "Practical Illustrations of the Achromatic Telescope," by Andrew Ross, and in looking it over, I see that one or two corrections have been made in the formula. These have been made by hand, and seem to have been made by some person, possibly Mr. Ross himself, before the book was issued to the public. Comparing it with the formula which you give upon page 445, in the centre of the middle column, I find that the part "$\frac{f'}{R'c}$ be called $c$" is corrected to $\frac{F''}{R'c}$, that is to say, the small $f'$ with one dash is changed into a capital F, with two dashes. This is important, as the small $f$, with one dash, represents the flint focal length, while capital F, with two dashes, represents the combined focus. A little further down I find that the fourth expression within the large brackets, the numerator of which is $(c' + 2 + b)\, g'$ is also altered, the sign of $b$ being minus and not plus. Also in my copy the denominator of the second expression reads:—$c\,(a'c + a' + 1)^2$, the second $c$ having a dash instead of being without one; also the denominator of the fourth expression appears C' with the dash, and not plain C. These various changes would materially affect the result of any calculations from these formulæ—indeed anyone of them would vitiate the result—and if you could throw any light upon the matter, and say which is the correct one, you would confer a benefit upon many who are interested in these investigations, and very much oblige.—ASCALON.

[56087.]—**Dynamo.**—Will Mr. Bottone please explain the cause of the following? When using my dynamo, which is shunt wound and gives an E.M.F. of about 10 volts, with a small induction coil of about ⅛in. spark, I am unable to get any appreciable length of spark from the secondary coil, although with a small bichromate cell I can easily obtain ¼in. Is it owing to the extra current in the condenser returning through the machine—how could this be prevented? Also, would he be kind enough to tell me the proper position of commutator with respect to the wire coils in Siemens armature, when the brushes are nearly horizontal, being inclined slightly in direction of rotation?—NAVAL.

[56088.]—**Knife-Cleaning Machine.**—In a family of 10 or 11, it is always a difficulty to get over the daily knife-cleaning with the ordinary board. I should be glad if any fellow reader can put me in the way of making a revolving machine, without of course infringing any patents. I want, if possible, to make one to take six knives at a time, and shall be glad of sketches, giving interior and exterior, in sections, &c.; no matter how rough a sketch, so that our kind Editor can reproduce it in our columns.—ARVONIA.

[56089.]—**Fasting and the Jews.**—Will some of your readers kindly say what a Jewish fast is? I know it is once a week from eve to eve; but does it mean during period, that absolutely no food or drink are taken; also what are Passover cakes? The Jews are said to be a healthy people, and have long life. It may be in part owing to their periodical fasts, giving the organs a rest, which, in this busy age, we seem to have no time to do, for if we work we must eat. Nevertheless my own experience teaches me that a fast, as far as I have gone, seems beneficial, both clearing the mind and the body. I should be much obliged by an answer.—S.

[56090.]—**Self-Lubricating Bearings.**—Would some engineering correspondent be good enough to inform me if lignum vitæ bushes, to wood rocking bar, and connecting rods (or traces) would be self-lubricating? Also are there such things as plumbago bushes, requiring no lubricating, and how can they be made?—R. H. T.

[56091.]—**Water Capacity of Boiler.**—To "YAMA" OR "MODDING."—Boiler should be 15ft., not 17½ft.; flue 3in. off bottom, and 3in. below gauge. Please work it fully in simple arithmetic.—T. HAWKINS.

[56092.]—**Altering a Dynamo for Plating Purposes.**—I have a D4 Cuttris dynamo machine, which I use for lighting, and I wish to know if I can alter it, so as to use it for electro-plating, or whether it would be best to buy another specially for plating?—RAT.

[56093.]—**Pitch Grease.**—Will some of our readers give me a little information how to make pitch grease, for to put on hot necks in sheet and tin mills. I have some tallow on hand, and I should like to know what is the composition, and how to boil and mix it.—SEA BORN.

[56094.]—**Iron Brake Pipes.**—Wanted details or a sketch of the iron brake pipes, with joints, now tried on the Great Eastern, North Eastern, and Brighton lines, in place of hose, between the carriages.—BRAKE.

[56095.]—**Gramme Machine.**—I have a Gramme armature of 5in. diameter, with a resistance of three ohms between two opposite pieces of the commutator. I should be obliged if some reader of "E.M." would tell me whether the resistance is such that a useful machine could be made out of it; or if the resistance is not right, what ought it to be?—J. D. L.

[56096.]—**Amalgamating Zinc.**—Will some one kindly tell me how to amalgamate zinc for a Daniell cell? I got a cell to work with a new zinc, but it has ceased since the mercury has gone off. I have some mercury that has been bottled up for about 20 years—will this do for the purpose? It has never been turned out of the bottle, nor does it stick to the glass.—W. J. GRIFFITHS.

[56097.]—**Conics.**—Three tangents are drawn to a parabola, such that the tangents of the angles which they make with the axis of the parabola, are in harmonical progression. What is the area of the triangle inclosed by them?—GEO. SMITH.

[56098.]—**Grinding V Tools.**—What is the best way to grind V tools for screw-cutting? Can I get a gauge for grinding to, and for setting them square with the work?—JUNIOR.

[56099.]—**Faulty Leclanche.**—Would some brother reader of the "E.M." kindly explain the following?—A short time ago, one of my Leclanché batteries ceased working altogether, which rather astonished me, as it had comparatively little work to do. At this I supplied it with a new zinc, washed the carbon and blocks, and recharged it with sal-ammoniac, when it rallied a little, only to return to be as bad as ever. What more astonished me is, that the other batteries, which have more work to do, require no attention at all, and work most satisfactorily. Would the fault lie with the agglomerate blocks or the carbon?—A. J. G.

[56100.]—**Oxyhydrogen Lantern.**—To "INVICTA."—What are the American composite gas bags? Information much requested.—OXYGEN.

[56101.]—**Spinning Wheel.**—Will some reader tell me how to make a spinning wheel?—SPINNER.

[56102.]—**To Mr. Lancaster or Mr. Bottone.**—I am constructing a small coil, about 2¼in. long between the ends, wound with two layers of No. 18 c.c. as primary, and 2oz. No. 36, as secondary, and insulated with brown paper, soaked in paraffin between each layer of wire. I want to know what quantity of tinfoil to use for a condenser, and how best to make the connections with the coil, also what size and kind of battery to use? This information, and any other hints, will oblige.—MODEL.

[56103.]—**Electric Accumulator.**—I want to make an accumulator to run a Cuttriss motor, latest pattern. I use the motor to work a small dental engine, and have to visit a country town once a month. I wish to avoid taking a large battery with me backwards and forwards, and as I should only require to run the motor one day a month, equal to about two or three hours continuous work, the remaining 29 days could be employed in recharging or storing the accumulator. Could this be done by a Daniell, Leclanché, or other constant battery, not requiring frequent renewal? I hope S. Bottone, "Nun Dor," "Sigma." or others will help me, or I shall be glad if they can give me the title of some inexpensive work or brochure on accumulators that will impart the required knowledge?—C. S. B.

[56104.]—**Gasoline Gas Engines.**—With the Editor's permission, will "Invicta" kindly send sketch and description of the cylinder, admission-valves, and firing arrangements of the simplest kind for a gas-engine of about ½ horse-power, and using gasoline vapour. I wish to construct one myself. The sketch only need show the cylinder (with dimensions and length of stroke) but with a particularly clear view and description of the simplest efficient valve arrangement for the admission of the gas and air to the cylinder, and the simplest firing device; the principle to be non-compression.—GASOLINE.

[56105.]—**Lever Fusee.**—Would any of our watchmaking readers kindly give me a hint that would enable me to recut the turns of a lever fusee that has been damaged by the over-running of the chain? I have experimented on an old verge fusee, but have not been very successful, and am therefore afraid to attempt the job in question.—O. C. T.

[56106.]—**Gun-Barrel Browning.**—Many thanks to "Armourer" for information on the above. Will he please say whether there is any difference in the mixture or application for laminated steel barrels? I have done my ordinary simple muzzle twist pigeon gun with success. I have tried my double central fire steel laminated barrels. After the first coat or two, the figuring begins going out of sight at the breech end, and by the fifth coat it is all out of sight all over the barrel. I have tried it three times, the same as I tried my single one, but each time, by the time I had finished, there was not the slightest figuring in them. Will he please help me out of the difficulty, or some other brother reader who has had experience?—A. Z.

[56107.]—**L. and N. W. Locos.**—Can any reader of "Ours" oblige with dimensions of the inside cylinder single-saddle tanks, with outside frames, which ran on the Manchester and Liverpool section of the L. and N. W., about 10 years since? Also of the four coupled outside cylinder saddle tanks which followed these, and have been replaced in their turn by Mr. Webb's double-enders.—B.

[56108.]—**Microscopical Staining.**—Can any one of "ours" tell me what shops sell aniline colours in powder? I have inquired at every colour shop in this neighbourhood for aniline black and aniline green, without success?—B.Sc., Plymouth.

[56109.]—**Photo. Lenses.**—I have a portrait lens, 2¼in. diameter, 5in. back focus. Can that be considered an extra-rapid lens? Also what should be the different diameters of a set of five stops to suit that focus and diameter for studio work?—GWENT.

[56110.]—**Mill Bills.**—Will some of our readers inform me how to temper cast steel mill bills? Also what to use as flux when two worn-out ones are shut together to make one new one, and oblige?—P. M.

[56111.]—**A Legal Question.**—A local board, responsible for the maintenance of the roads of its district, lays down new metal over the whole width of a road, and when one portion of that becomes worn down the board places tressels—during the hours of daylight—over this worn portion, in order that the traffic may be diverted to the other parts of the road, so as to insure the equal wearing of the metal everywhere. The road is sufficiently wide to allow ample space for traffic without encroaching on the part guarded by the tressels. Is the putting up of such tressels an obstruction of the highway, in a legal point of view; and can the board be indicted in the event of an accident occurring to a carriage caused by the presence of the tressels?—G. C. C.

[56112.]—**Chemical.**—Will somebody give me directions for testing for As in wall paper? Has any way been described before in the "E.M."? If there has, in what number?—J. K.

[56113.]—**Clock.**—To SIR E. BECKETT.—Given the area and the length of the arms of a fly in a turret clock: to find the resistance of the air? How is it done?—J. K.

[56114.]—**Electro-Plating Dynamo.**—To MR. BOTTONE.—I have fitted up a dynamo whose F.M.'s weigh 30lb., and have 5lb. of No. 14 wire on each limb—

that is, 10lb. in all on the F.M.'s. This weight of wire gives me 7 layers on each limb. The armature is the ordinary H, is 6in long and 8in. diameter, and revolves in the tunnel of F M.'s, which is also 6in. long. The armature has 1lb. 6oz. No. 16 wire wound in the slot; kindly tell me how many volts, and how many ampères my machine should have?—Faraday.

[56115.]—**Gilding Watch Movements.**—Will any reader of "Ours" kindly describe the process of finishing a watch plate before gilding? I want to know how to get up the nice matted surface. If it is done with acid, state what should be done with the pivot holes, so that they may not be eaten too wide, and also the kind of acid used in the trade. State also how they are scratch-brushed so that no scratches appear; leaving the beautiful dead surface all our watch movements have.—Horologer.

[56116.]—**Brick Clays.**—We are just opening some fresh brick pits, and should be glad if anyone would tell us how the following analyses compare with other clays:

Red Earth.

| | |
|---|---|
| Chlorine | ·034 per cent. |
| Saltpetre | ·0015 „ |

White Gault.

| | |
|---|---|
| Chlorine | ·1 per cent. |
| Saltpetre | ·008 „ |

—Brickburner.

[56117.]—**To Mr. Bottone.**—Will you kindly give diagram of winding and connecting up of Pacinotti ring, as I am at a loss to understand the diagram given by you in No. 1012 of "Ours"?—J. P. M.

[56118.]—**American Gas Bags.**—Will "Invicta" be good enough to give full instructions for making the American composite gas bags; giving particulars of the materials of which they are made, how to put them together; where the materials may be procured, and the size he has made his?—M. A. G.

[56119.]—**Magnitude of Small Stars.**—Will "F.R.A.S.," or any other astronomical reader, kindly inform me if there is any reliable formula for ascertaining the magnitude of the smallest star visible in any given aperture, and if so, to whose scale does it apply—viz, Ba., Sm., H., or A.? Please give formula.—H. A.

[56120.]—**University.**—A young man, aged nineteen, the son of a clergyman—income limited—wishes to get some exhibition or scholarship to enable him to go to Cambridge. A year ago he was some ten places below the successful candidate for an exhibition in a classical examination at Cambridge, but has improved since that time. He has a fair knowledge of elementary mathematics. —R. B. R.

[56121.]—**Canine.**—A pet dog—a Yorkshire toy terrier—is troubled with scurf and is losing its coat. Is it a good thing to wash with borax and water?—W. H. B.

[56122.]—**Small Brace.**—Will "Invicta" please oblige us with sketch of small brace for drills, from 1-32 to ¼in. for brass work, &c.—Four of Us.

[56123.]—**Wire for Dynamo.**—To Mr. Bottone.—I have a small H armature 5in. long, on to which I can wind about 1½lb. of No. 18, B.W.G. (of which I have a large quantity); how much must I wind on each field magnet to properly balance same with armature, and what power could be obtained from same?—C. W.

[56124.]—**L. B. and S. C. Engines.**—Can anyone give me principal dimensions of the London Brighton and South Coast engines known as the "Terrier" class, or state where I could get full particulars?—F. M. C.

[56125.]—**Staining Buckskin.**—I wish to stain a pair of buckskin gloves mouse colour. Could I mix anything with the pipeclay I use for cleaning them to produce the desired shade, or is there anything else that could be similarly applied? The gloves must not be made too wet, or they will shrink.—D. G.

[56126.]—**Chemical Examination, London University.**—Which are the most important articles of Gill's "Chemistry" for the purpose of passing the London Matriculation Examination in this subject? I cannot afford time to read the whole, or the greater part, of the work.—Londoniensis.

[56127.]—**Turning Small Cranks and Setting Lathe heads.**—Will any expert kindly tell me the best way to set about turning small cranks, say about ⅜in. diameter? I am in a fog as to turning pin. I find my lathe heads have side-play. I should be glad to know the way to find out if they are perfectly in line, after lining them up to fit lathe bed.—H. J. S.

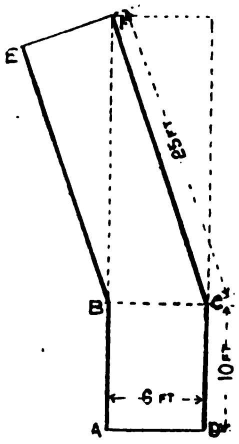
[56128.]—**Engine and Boiler.**—I should be obliged if some reader of the "E.M." would answer through this paper the following questions. I am making a loco. engine boiler 2ft. long by 9in. diameter, I want to know what will be the proper size of slide-valve cylinders for such a boiler? I have a pair 1in. by 2in. stroke—would they be of any use? I intend making it on the compound principle. Also how many tubes and what diameter should they be, the firebox is about 8in. square, inside measurement: and what pressure could I keep up with such a firebox; boiler is double riveted, and is full ¼in. thick. I should be much obliged if these questions could be answered on the 20th.—Compound.

[56129.]—**Legal.**—Will anyone of "ours" answer? A. and B. are executors to, and duly prove, a will which leaves £700 to a boy when he in some years hence comes of age. By arrangement the money is deposited in a bank, in the joint names of A., B., and C., C. being the boy's father. The boy attains age, but in the meantime B. has become insolvent and cannot be found. (1.) Can A., C., and boy without B., draw the money? (2.) Is B. actionable at law for not coming forward? (3.) If so, what punishment does he incur?—Parvus.

[56130.]—**Pau.**—Would any of your readers kindly give me some information relative to Pau as a winter residence. What is the most reasonable mode of living for a gentleman's family? Can good musical and other education be obtained? Any information regarding cost and mode of living and climate would be acceptable. Are there any pleasant summer resorts in the neighbourhood?—Alpha.

[56131.]—**Full Moon and Lunar Cycle.**—Will "F.R.A.S." or some other astronomical reader of the "E.M.", say if there will be a full moon in February, 1904; and also describe the process by which the fact is ascertained. The moon was full this year March 1; but 1904 being a leap year, if the full moon of Jan. 30 be repeated on the completion of the lunar cycle, the moon will that year be full in February. I find a difficulty in reckoning the leap years, and allowing for the fraction of a day's difference in each cycle.—Leo.

[56132.]—**Cutting Wrought-iron Pipes to any Angle.**—Will any kind reader of the "E.M." inform me how to cut large pipes, such as funnels for steamers or large ventilators? I have seen two or three ways, but never a proper fixed rule. The sketch will show what is wanted, the plates to be cut before they are bent. A B C D is square. B to E is the length I want. I have done it by measurement on paper, but it is not convenient in practice, when the pipes are of large diameter—M. B. M.



[56133.]—**Milling.**—Would any kind reader give a detailed description of a milling attachment for a 5in. centre s.c. lathe, vice for holding work and adjusting for height, &c.—Belgian.

[56134.]—**Taps and Dies.**—I have a good screw plate and indifferent taps, and I am making other ones which I want to finish well. How must I file them or groove them to obtain good inside threads? My object is to thread little brass binding screws, and other electrical small pieces. The screws must go in and out freely and not shake.—Belgian.

[56135.]—**Value of Gas Liquor.**—What percentage of ammonia does gas liquor contain? how much sulphate will it make? and what is a fair price for liquor at gasworks? The liquor to be fair average quality. —Sulphur.

[56136.]—**Composition of Gas Lime (from dry Process).**—Of what does this consist, and in what quantities?—Sulphur.

## CHESS.

All Communications for this department must be addressed to J. Pierce, Llandwrog, Carnarvon.

We are glad to inform our readers that a sufficient number of problems having been sent in for the Tourney, it will not have to be abandoned. We propose, however, to defer starting it until March 31st, in the hope that a few more may appear in the mean time. The Solution Tourney will begin simultaneously. Of course, any competitors who have already sent in their problems are at liberty to alter or withdraw them up to that date if they think fit.

### NOTICES TO CORRESPONDENTS.

Correct solutions to 928 by Raymond, J. E. Piper (fine problem), and Rev. W. Anderson (Old Romney).

## ANSWERS TO CORRESPONDENTS.

⁂ *All communications should be addressed to the* Editor *of the* English Mechanic, 332, *Strand, W.C.*

### HINTS TO CORRESPONDENTS

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

⁂ **Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.**

### A NEW VOLUME.

The last number was the first of Vol. XLI. Readers willing to oblige us by recommending "Ours" to new subscribers should do so now, when a new volume is commencing. The index to Vol. XL. will be published next week, and cases and bound volumes will be on sale shortly after. Readers desirous of making up their sets for binding the past volume are recommended to do so at once, as the back numbers soon run out of print.

**The following are the initials, &c., of letters to hand up to Wednesday evening, March 11, and unacknowledged elsewhere:—**

Chas. Bright.—D. W. Armstrong.—A. J. Adams.—W. Donald.—C. Birchall.—British Gas Engine Co.—Prof. Patrix.—R. Mills.—R. T. Omond.—G. Riddiford.—F. A. Davis.—Allan Bros.—C. M. C.—E. J. S.—Jod.—Hopeful.—J. Kean.—J. Rance.—A. J. B.—C. H. Carter. —Yesallaw.—Plate Worker.—Burner.—Gramme.—Loco. Draughtsman.—E. A. K.—Argent.—B. Harcourt. —David.—H. A. Wassell.—J. E. Floyd.—A. W.—Subscriber.—Asterisk.—J. B. Valetta.—F. C. S.—Uncas.

Younker. (Are not the instructions given sufficient? The simplest form of bath of the kind is an old chair, a spirit lamp, and a good blanket. For full details how to make vapour and hot-air baths see Vol. XXXV. pp. 130, 157, 181, 289, 354, 378, 384, 403, 454, 597, 599. 2. What is it you mean? There are dry batteries; but chemical action must go on when the current is produced.)—N. Y. T. (Yes, an error of the types. It was Vol. XXIII., in which the "E.M." telephone was described. The No. and Vol. are both out of print, but we quoted the pith for you.)—E. Hugo. (See p. 341, No. 925. They are made of pieces of copper and zinc separated by cloth kept moist with salt or acidulated water.)—A Sufferer. (What is the cause of the enlargement? If rheumatic gout, we are afraid you will not find a remedy. See pp. 211, 215, 452, Vol. XXXIV.)—J. S——, Chelmsford. (You will find such statistics in the returns made to the Board of Trade, which are published by the Queen's printers, Messrs. Eyre and Spottiswoode, East Harding-street, E.C.)—X. Y. Z. (Procure a catalogue of books from Messrs. Macmillan, Bedford-street, W.C.)—G. E. (Surely you know that a blowpipe lamp on the same principle is used to burn off paint. Depends on what you call "expensive"; it is about as cheap as anything else, and it will heat anything of moderate size. 2. Why not go to a tool-shop and ask them to show you one?) —V. Bottom. (Of what interest would such information be, and who is to know whether it would be correct?)—W. R., Notts. (The upper part of a carriage wheel moves faster than the lower. Plot it down on a piece of paper, and you can then measure how much.) —John L . . . (For prices apply to the manufacturers. About one penny per hour per horse-power; but the gas-engine does not use so much gas when running light.)—Irresolute. (The usual method of making books sell is to advertise them. 2. The usual way is to measure, or refer to a table in which the diameters are given.)—J. H. Edwards. (It would be cheaper to give the parts out to different workers. Phosphor-bronze would be a suitable metal, but rather expensive; aluminium would be cheaper.) —Daniel Rome. (Would not Bourne's "Catechism of the Steam Engine" suit you? It is published by Longmans.)—Model. (The paint is usually mixed with stoving copal, and the articles are generally stoved. See pp. 139, 374, last volume.)—Hydrogen. (It can be done by causing it to revolve for some time in all possible positions before a powerful magnet or between the poles of a dynamo. See an article on the demagnetisation of watches in No. 762.)—Lux. (See p. 481, No. 982, and the indices generally for several methods of making oil gas. 2. Pocket batteries have been described many times. See p. 119, No. 1019, for description of a good dry battery.)—A New Reader. (See the indices, or No. 967, p. 99, for instance.)—Veritas. (There is a good deal about zincography in Vol. XXVII. The processes are much the same as in lithography; but zinc plates are used instead of stones. We do not think cylinders could be used with advantage. Better purchase the inks. The rollers are made with wood, covered with flannel, and an outer skin of fine calf.)—H. R. R. (Try David Nutt, Strand, W.C., or Williams and Norgate, Henrietta-street, Covent-garden, W.C.)—W. H. L. (There are several recipes, but the following makes a good brown hard: Gum sandarac, 3lb.; shellac (brown), 2lb.; methylated spirit, 2 gallons. Dissolve. Add a quart of turpentine varnish, shake up well, and strain. If by white polish you mean the finish, dissolve two drachms of benzoin and the same quantity of picked shallac in half a pint of "pure" methylated alcohol, and add about 2 teaspoonfuls of poppy oil.)—Chemicus. (What is it you mean? It must be made large enough for the given lens. See back numbers. 2. For burnishing photographs, see the indices. The roller press gives the best results; but you can use one of the preparations sold for the purpose.)—Gold Face. (Have you tried to precipitate it with common salt? You cannot get it darker than the pure gold will give. You must use alloy, for which see back numbers, or one of the handbooks of the art.)—A Collar Maker. (See the indices for recipes, and use a rubber or steel-faced stamp.)—Amateur. (Yes, or gun-metal.)—Woodrouffe. (Something wrong, evidently; but how that is to be found out by inserting your query we fail to see. You must carefully follow the instructions and trace out yourself; but see some recent replies.)—T. Cridland. (Consult a medical man. He must examine you. No one else can give useful advice.)—Silver. (Of course, if there were enough cells. One cell would not, if that is what you mean. For directions to make, see indices.)—B. H. F. (Why not write to the makers? The query would not be answered if inserted.)—Armature. (See Prof. S. P. Thompson's work on Dynamo Machines, or look through back volumes.)—Reader of "E. M." (Miller's "Chemistry" is in three volumes, published by Longmans. They also issue Miller's "Introduction to Inorganic Chemistry" in their Textbook Series, price 3s. 6d.)—Racquet. (It is quite satisfactory if properly laid.)—Friar Bacon. (For painting lantern slides, see No. 946, p. 226.)—Dan. (The methods of ascertaining power of engines of all kinds have been given often enough, surely. They will be found in the pocket-books. Dixon Kemp's work, published at the *Field* office, we believe, is the best work on yacht building.)—Centrifugal Pump. (Why waste your time in "arguments" of the kind? Your friend is either playing on the words "height of 100ft," or he knows nothing about it. A centrifugal pump will draw water from a depth of 25ft., and that is about all it will do efficiently. At 20ft. it will do much better work. Why not procure an elementary textbook, and argue over that?)—G. U. B. (Two methods of making dark slides in No. 979. In No. 958 he described the camera.)—Nemo. (The company issue a book describing all the parts, or you will find the information in Reynolds's "Continuous Brakes," or in back volumes—the numbers are out of print.)—Drone. (See the indices for several recipes. Is it not too late now?)—Non. (The best information on those points is to be obtained only by practice. We know of no book on the subject.)—J. G. (All information about appointments in the Civil Service can be obtained from the Civil Service Commissioners, Cannon-row, S.W.)—A. H. T. V. (We do not remember it. There is no "practical" work on the subject, but several on the principles.)—G. Pardoe. (We cannot find space for all the queries about dynamos that reach us—especially when they involve diagrams which will probably be of no use but to explain the meaning of the individual querist. Surely enough has been said lately to guide you as to the quantities of wire.)—Chas. Trotman. (Yes, a weak solution of sulphuric acid. 2. Several recipes for marking-ink in back volumes. 3. All the directions for removing ink with oxalic acid state that the resulting brown stain must be removed with a weak solution of chloride of lime. 4. Payen's "Industrial Chemistry," Longmans.)—F. S. D. (Horehound beer, pp. 462, 483, Vol. XXXVI., and other recipes in back volumes. 2. There are public analysts in London who, under the Adulterations Act, make analyses of articles of food for a small fee. You can ascertain the scale on application to them, and can have their addresses at the police-station of the district.)—T. E. L. (The letter, if stamped, could be produced in court as evidence of your acceptance of the situation.)—Sammy. (Yes, we think so; the fortnight's notice has evidently become customary.)—J. T. (No room to spare, but you will find a good epitome of recipes, household hints, games, &c., in the *Weekly Times* every week, in the column headed the "Home Circle.")

**Dr. Carter Moffat's Ammoniaphone** (Harness' Patent). This excellent invention for strengthening and improving the voice, and for curing ASTHMA, BRONCHITIS, and all pulmonary affections, of which a full description, illustrated by a sectional view of the instrument, appeared in the English Mechanic for Dec. 26th, has been secured by the Medical Battery Co., 205, Regent-street, London, W. Its efficacy is vouched for by the highest medical, scientific, and social authorities, and Dr. Carter Moffat attends daily at 205, Regent-street, London, W., to demonstrate its extraordinary utility. Residents at a distance should write for "The History of the Ammoniaphone," sent post free to any address. Dr. Carter Moffat's Ammoniaphone will be sent post free to any address on receipt of P.O.O. or cheque value 21s., and payable to C. B. HARNESS, The Medical Battery Co., 205, Regent-street, London, W.—[Advt.]

An explosion of natural gas has occurred near Pittsburgh. Much injury was done, and six persons were killed.

It has been resolved to hold an international exhibition of industry, science, and art in Edinburgh next summer.

☞ A CHANCE OF A LIFETIME!

£10,000 IN PRESENTS TO SUBSCRIBERS!

This Offer Good till May 15th, 1885, Only.

GRAND CAPITAL PRIZE OF £1000 IN CASH.

The most magnificent offer ever made by a reliable publisher. THIS IS A CHANCE OF A LIFETIME FOR YOU. The proprietors of THE HOUSEHOLD JOURNAL have determined to outdo all former efforts of other publishers, by giving one of the following Grand Presents to every one who subscribes between NOW AND MAY 15th. FOR ONLY TWO SHILLINGS Or Twenty-six Stamps, we will enter your name on our subscription books, and post pay to you regularly for Six Months our Illustrated Family Publication, THE HOUSEHOLD JOURNAL, and also send you a printed numbered receipt which will entitle you to one of the following Magnificent Presents:

LIST OF PRESENTS TO BE AWARDED OUR SUBSCRIBERS:

| | | | | | |
|---|---|---|---|---|---|
| 1 | Cash Gift | £1000 | 50 | Boys' Silver Watches, £2 each | £100 |
| 1 | Cash Gift | 500 | 50 | Ladies' Watches, £2 each | 100 |
| 1 | Cash Gift | 200 | 500 | Cash Presents, £1 each | 500 |

Together with 193,747 useful and valuable articles, worth from One to Two Shillings each, making a total of 200,000 valuable and useful articles to be given to our Subscribers on MAY 15th, 1885, so that each and every one who subscribes before that date will receive THE HOUSEHOLD JOURNAL six months and a beautiful Present besides. The Prizes will be awarded MAY 15th, 1885, full particulars of which will be given hereafter, and published in the Journal. Subscribers can have Presents forwarded to any part of the United Kingdom. Printed lists of the awards will be forwarded to all Subscribers, and also published in the JOURNAL immediately after the award.

THE HOUSEHOLD JOURNAL Is one of the most BEAUTIFUL and POPULAR MAGAZINES OF THE DAY. It contains Twenty Large Pages, and has an elegantly engraved, illustrated, and tinted Cover. It is replete with beautiful illustrations and choice literature. No expense is spared to make this publication one of the finest in the world.

REMEMBER, WE MAKE NO CHARGE for these presents. The Two Shillings is the regular subscription price for six months to the JOURNAL, and some one is sure to get a Grand Prize of £1,000. OUR PROFIT will come from our advertising patronage, which will be very large, at remunerative rates. We want 200,000 new subscribers before May 15th, and as we are now receiving daily as many as 8,000, we are sure to get the required number. There will be no postponement. Persons wishing to subscribe for a year will receive two receipts for Four Shillings or 52 stamps, entitling them to a year's subscription and two presents.

REMEMBER, we send the JOURNAL direct to your address, post paid, and enclose a numbered receipt for each six months' subscription in the first number you receive.

A FREE SUBSCRIPTION TO YOU.—If you will get five friends to join you, and send us Ten Shillings all at one time, we will send six subscriptions for six months and six numbered receipts, good for six presents. Send Twenty Shillings at one time, with the names of ten friends or acquaintances, and we will send twelve subscriptions and twelve numbered receipts, and so on, thus giving you an extra receipt and subscription for every five subscribers you send in, and each subscriber gets a numbered receipt, and will get one of the presents mentioned above. The JOURNAL is sent, post paid, direct to each subscriber's address you send us.

SEND MONEY by Registered Letter or P.O. Stamps should not be sent when P.O. can be obtained. SPECIMEN COPY, 4d.

Address—THE HOUSEHOLD JOURNAL, H. C. Edwards, Manager, 31, Bouverie St.,
FLEET STREET, LONDON, E.C.

CUT THIS OUT AND SHOW IT TO YOUR FRIENDS, NEIGHBOURS, AND ACQUAINTANCES, AND PERSUADE THEM TO JOIN YOU, AND THUS GET YOUR OWN SUBSCRIPTION AND RECEIPT FREE. AGENTS WANTED

**Every Workman connected with the Building Trades requiring a Situation should advertise in "THE BUILDING NEWS," published every FRIDAY, price Fourpence at 332, Strand, London, W.C.**

"THE BUILDING NEWS" is the Principal Journal representing Architects and Builders, and has the largest circulation of any Professional Journal in the kingdom.

Every Workman should insist on seeing "THE BUILDING NEWS" every week at his Club or Coffee House. He will find more "Lists of Tenders" for new work in it every week than in any similar paper, and can thus judge where work is likely to be had. He is also specially invited to make use of "Intercommunication" if he wants to know anything about his trade; to write to the Editor if he has any suggestions to make, and to advertise in the paper when he wants work.

The charge for Advertisements for Situations is On Shilling for Twenty-four Words, and Sixpence for every Eight Words after

## TERMS OF SUBSCRIPTION.

PAYABLE IN ADVANCE.

6s. 6d. for Six Months and 11s. for Twelve Months, Post-free to any part of the United Kingdom. For the United States, 13s., or 3 dols. 26c. gold; to France or Belgium, 13s., or 16f. 50c.; to India (via Brindisi), 15s. 2d.; to New Zealand, the Cape, the West Indies, Canada, Nova Scotia, Natal, or any of the Australian Colonies, 13s.

The remittance should be made by Post-office order. Back numbers cannot be sent out of the United Kingdom by the ordinary newspaper post, but must be remitted for at the rate of 4d. each to cover extra postage.

Messrs. James W. Queen and Co., of 924, Chestnut-street, Philadelphia, are authorised to receive subscriptions for the United States for the ENGLISH MECHANIC, at the rate of 3 dols. 26c. gold, or Thirteen Shillings per annum, post-free. The copies will be forwarded direct by mail from the publishing office in London. All subscriptions will commence with the number first issued after the receipt of the subscription. If back numbers are required to complete volumes, they must be paid for at the rate of 4d. each copy, to cover extra postage.

Vols. IV., VII., XXVI., XXVIII., XXX., XXXII., XXXIII., XXXIV., XXXV., XXXVI., XXXVII., XXXVIII., XXXIX. bound in cloth, 7s. each. Post free, 7s. 9d.

Vol. XL. ready shortly.

All the other bound volumes are out of print. Subscribers would do well to order volumes as soon as possible after the conclusion of each half-yearly volume in February and August, as only a limited number are bound up, and these soon run out of print. Most of our back numbers can be had singly, price 2d. each, through any bookseller or newsagent, or 2½d. each, post-free from the office (except index numbers, which are 3d. each, or post-free 3½d.)

Indexes for Vols. I., VI., VII., VIII., and IX., 2d. each. Post free 2½d. each. Indexes to Vol. XI. and to subsequent vols., 3d. each, or post free, 3½d. Cases for binding, 1s. 6d. each.

**Epps's Cocoa.**—Grateful and Comforting:—"By a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by a careful application of the fine properties of well-selected Cocoa, Mr. Epps has provided our breakfast tables with a delicately flavoured beverage which may save us many heavy doctors' bills. It is by the judicious use of such articles of diet that a constitution may be gradually built up until strong enough to resist every tendency to disease. Hundreds of subtle maladies are floating around us ready to attack wherever there is a weak point. We may escape many a fatal shaft by keeping ourselves well fortified with pure blood and a properly nourished frame."—*Civil Service Gazette*.—Made simply with boiling water or milk. Sold only in packets, labelled—"JAMES EPPS and CO., Homœopathic Chemists London."—Also makers of Epps's Chocolate Essence

## CHARGES FOR ADVERTISING.

| | s. | d. |
|---|---|---|
| Thirty Words | 2 | 6 |
| Every additional eight words | 0 | 6 |

Front Page Advertisements Five Shillings for the first 40 words, afterwards 6d. per line. Paragraph Advertisements One Shilling per line. No front page or paragraph advertisement inserted for less than Five Shillings. Reduced terms for series of more than 6 insertions may be ascertained on application to the Publisher.

ADVERTISEMENTS in EXCHANGE COLUMN—for

| | s. | d. |
|---|---|---|
| Twenty-four words | 0 | 3 |
| For every succeeding Eight words | 0 | 3 |

ADVERTISEMENTS in the SIXPENNY SALE COLUMN.

| | s. | d. |
|---|---|---|
| Sixteen words | 0 | 6 |
| For every succeeding Eight Words | 0 | 6 |

*** It must be borne in mind that no Displayed advertisements can appear in the "Sixpenny Sale Column." All advertisements must be prepaid; no reduction is made on repeated insertions; and in cases where the amount sent exceeds One Shilling, the publisher would be grateful if a P.O.O. could be sent, and not stamps. Stamps, however (preferably halfpenny stamps), may be sent where it is inconvenient to obtain P.O.O's.

The address is included as part of the advertisement, and charged for.

Advertisements must reach the office by 1 p.m. on Wednesday to insure insertion in the following Friday's number.

## NOTICE TO SUBSCRIBERS.

Subscribers receiving their copies direct from the office are requested to observe that the last number of the term for which their subscription is paid will be forwarded to them in a Pink Wrapper, as an intimation that a fresh remittance is necessary, if it is desired to continue the Subscription.

**Holloway's Ointment and Pills.** — Coughs Influenza.—The soothing properties of these medicaments render them well worthy of trial in all such diseases. In common colds and influenza the Pills taken internally and the Ointment rubbed externally are exceedingly efficacious. When influenza is epidemic this treatment is easiest, safest, and surest.—[Advt.]

NOW READY,
HANDSOMELY BOUND IN CLOTH,
VOL XLVII.
OF THE
BUILDING NEWS,
PRICE TWELVE SHILLINGS.
Order at once of any bookseller, as only a limited number are bound up.

## OUR EXCHANGE COLUMN.

*The charge for Exchange Notices is 3d. for the first 24 words and 3d. for every succeeding 8 words.*

**Good Value Offered** (cash or instruments) for all kinds of sound or repairable Scientific Appliances.—CAPLATZI, Science Depot, Chenies-street, near British Museum. Established 1852.

**Garden Roller**, stone, with nice iron handle, was the property of the Poet Laureate, Wordsworth, of Rydal Mount. What offers? Sufficient proof given.—Mr. VINNE, 22, Brunton-place, Carlisle.

**Electrical Apparatus** (new) in exchange for other Scientific Apparatus, electrical or otherwise.—Send description, sizes, &c., of goods, to HINDLE, Irwell Vale, Helmshore.

**Electrical Apparatus.**—Glass Cylinder, 12 by 7-stool, &c., all complete, in wood box, all equal to new; suit lecturer or schoolmaster. Offers requested.—H. MORETON, Watchmaker, Masham Bedale, Yorks.

**Organ Bellows**, several sizes, also Windchests, quite ready for pipes, &c. Exchange for musical books or instruments.—W. JOHNSON, 12, Moxley, near Wednesbury.

Wanted, "**Spon's Dictionary of Engineering**," mechanical movements. Exchange.—A. C. BELL, Metallurgist, Main-road, Bexley Heath.

Vertical half horse-power **Engine**, quite new, disc, crank shaft, brass bearings. Exchange for camera.—JACKSON, Engineer, Bloxham.

**Castings and Forgings** complete of Engine and four sets of Fans. Exchange for magic lantern or camera.—JACKSON, Engineer, Bloxham.

Splendid ivory-handled **Knife**, best quality, contains three blades. Will exchange for novels or other books to value of 2s.—GILBERT, Oxford-road, Sheffield.

Wanted, 48in. or 50in. **Bicycle**. Exchange 7½in. centre Lathe Head, 24in. bellows and frame. Lot cost £4 10s. Other exchange.—W. SMITH, Bilston-road, Wolverhampton.

54in. "Rapid" **Bicycle**, balls to both wheels, nickel-plated, adjustable step, brake, &c. Exchange for Amateur's Portable Lathe, Tools, &c.—J. H. B., 17, Eardley-road, Streatham.

**Speculum**, silver-on-glass, 9 inches diameter, 6 feet focus, good definition.—DAY, 56, Driffield-road, Old Ford, London.

**Bicycle**, 50in., nearly new, hollow forks, bent handles. Exchange for good lathe, watch, or piano.—W. CROKER, 51, Sutherland-road, Bow, E.

Lot Jeweller's **Tools**. Want Lantern Views, Screen, Gas Bag.—67, Thomas street, Aston-road, Birmingham.

Quarter-plate **Camera**, focussing screen, dark slide, lens and good oak stand. What offers in cash? Nearly new.—Particulars to G. HEYS JONES, The College, Brighton.

Six volumes "**Harper's New Magazine**," bound, cost 17s. 28 parts of "Cassell's Concise Cyclopædia," cost 14s. Offers, electrical or bicycle, or offers.—W. W., 4, Ashton-road, Oldham.

Amateurs and others having good **Lathes**, Engines, and Boilers for exchange, should apply, CAPPS, Engineer, Hop Exchange, Southwark street, London, S.E.

**50in. Bicycle**, balls, complete castings, wire for hand dynamo; 6 vols. "Knowledge," small anvil, new Gem camera; anything useful, photographic preferred.—EVERS, Wath, Rotherham.

Will exchange a **Whitworth-Thread Stock**, Taps, Plugs, and Dies, 1in., ¾, and ⅞, perfect order: for a ¼in., ⅜, and ½in Whitworth's-thread stock, dies, taps, and plugs, and a few useful smith's tools.—TAYLOR, Milbourne-street, Blackpool.

2½ H.-P. **Vertical Engine**, very strong, with pump, complete; exchange for tricycle, harmonium, drilling machine, or useful exchange value £5.—WM. POATE, Havant, Hants.

Wanted, Vols. I., II., III. "**Amateur Work**," also "Scientific Recreations," publishers, Ward and Lock; exchange ½-plate camera and lens.—C. LUNN, Woodsome Lees, near Huddersfield.

Wanted, self-centring **Drill Chuck** and set of Twist Drills to ½in., in exchange for 8-air musical box, or Edison's electric pen and press.—C. LUNN, Woodsome Lees, near Huddersfield.

Cardboard **Model Locomotive**, well made, length 2 feet; what offers in exchange?—Write to JOHN WILLIMONT, Jun., St. Lawrence, Bodmin, Cornwall.

**Magneto** (parlour) **Machine**, on marble base, for photographic apparatus.—D. SCOTT, Crab-hill, Pontefract.

**Telegraphic Apparatus**, 3in. needles, gong, new, by C. &. Wanted, tourist's camera, with double backs or changing box, tricycle, &c.—TEAR, 12, Clapham-road.

"**English Mechanic**," Vols. XI. to XVI. inclusive, unsoiled and well bound. What offers? No cards.—HY. KAY, Esk Bank, Altrincham.

Model Horizontal **Engine**, cylinder 1in. bore, brass standard, on mahogany stand; exchange in lathe parts to 30s.—BLANCHARD, 29, Earl-street, Lisson-grove, London.

Astronomical silvered **Mirror or O.G.**, unmounted. Would like to exchange a MAGIC LANTERN for either of the above; lantern is complete with lamp and slide, cost 35s., new.—WILLIAM JAMES, 95, Victor-street, Walsall.

Wanted, a small **Lathe** or Heads. Will give in exchange photographic apparatus, books, mitring machine, watch tools, hand printing press, and clocks.—READ, 156, Wyndham-road, Camberwell, London, S.E.

Rippingille's Petroleum **Cooking Stove**, with oven and lamp complete, cost 25s., little used; exchange small lathe or scientific apparatus.—ABEL, Burford-road, Forest, Nottingham.

Will exchange B flat **Euphonium, Violin and** Bow, for a good 48 or 50 or 52in. bicycle.—J. S., No. 7, Todholes-road Cleator Moor, near Whitehaven.

Strong Horizontal **Slide-Valve Engine**, all bright, 1½in. cylinder, brass, 3in. stroke. Exchange for Lancaster's ½-plate Instantograph Lens complete, or offers in Photographic Apparatus.—BELL, 97, Margaret-street, West Gorton, Manchester.

Powerful **Medical Coil**, handles and battery, value 26s.; exchange 1lb. of No. 34 silk covered wire or spark coil.—54, Guildhall-street, Folkestone.

Massive 4ft. **Lathe Bed**, standards, 2 flywheels, double crank shaft, traction chain treadle, by "Milnes," Bradford. Exchange 50in Humber Pilot Invincible.—F. UNDERWOOD, Beverley.

**Change Wheels**, second-hand. Complete set, in good condition, 10 pitch, 1in. hole in box, wanted. What offers? Exchange.—L. C. M., 4, Leamington Villas, Redland, Bristol.

"**English Mechanic**," No. 932 to present number, four volumes complete with indices. Want 3in. Lathe Castings. Offers?—T. TANNER, New Tredegar, via Cardiff.

**Lathe Wheel**, 28in., 95lb., 4ft. crank, turned iron treadle lathe standards, 100 ENGLISH MECHANICS, 3-horse engine bed. Exchange.—W. SMITH, Bilston-road, Wolverhampton.

866 to 1,040 "**English Mechanic**"; 24 monthly parts "Amateur Mechanic;" 40 monthly parts "Amateur Work;" 39 monthly parts "Cassell's Popular Educator;" 13 monthly parts "Cassell's Technical Educator;" "Lathe and its Uses," cost 16s. What offers, cash or exchange.—W. G., 7, Edward-street, South Shields.

**Dynamo**, 60-light, nearly complete, ready for winding. Exchange for B flat Cornet, or offers to value of £5.—A. J. S., 188, Mare-street, Hackney, E.

**Boiler**, iron, copper riveted, 5in. by 16in.; Drilling Cramp, Drills, and Swag, Magnetic Electric Machine. What offers?—A. W., 16, West-street, Stratford New Town, Essex.

What offers for 225 numbers of the "**English Mechanic**," unbound? Tools wanted in exchange, or offers.—W. H. ALLEN, 46, Quick-road, Chiswick.

Very best **Cast Steel** for Tools, ⅜ to ⅞, octagon, cost 60s. per cwt. Offers requested.—GILBERT, Oxford-road, Sheffield.

What offers for first three half vols. of "**Blackie's** ENCYCLOPÆDIA," new. Anything useful.—JOHN, Kempston, Bedford.

Wanted, offers for Vols. XXXVII., XXXVIII., and XXXIX, and XL ENGLISH MECHANIC, in numbers, clean and complete.—J. HANSON, 15, Wheatholme Cottages, Cloughfold, near Manchester.

Powerful **Shocking Coil**, Water Regulator, and Battery; for Silver Albert or anything useful.—D. EVANS, 39, Burdett-buildings, Westminster Bridge-road.

## THE SIXPENNY SALE COLUMN.

*Advertisements are inserted in this column at the rate of 6d. for the first 16 words, and 6d. for every succeeding 8 words.*

Mackie's Patent wrought-iron **Spring Pulley** best in the world.—Sole Manufacturers, J. and J. MACKIE and Co., Reading.

**Plating.**—Every description of Gilding, Silver Plating, Oxidising, and Bronzing, executed with very best finish. Speciality in nickel-plating. Special quotations on application. Send one stamp for price list. Small jobs attended to per return post.—MORRIS COHEN, 132, Kirkgate, Leeds.

**Lunt's** is the noted house for Tools. Send four stamps, revised reduced illustrated catalogue, 80 pages.

**Parallel Bench Vices**, steel jaws, grip 3½, 9¼lb. 10s.; 4, 18lb., 15s. 6d.; 4¾, 28lb., 21s.—LUNT's.

**Planes.**—New London Smoothing, finished or ready for fitting.—A. S. LUNT, Tool Maker, 297, Hackney-road, E.

**Fretwork.**—Illustrated Catalogue of every requisite and 400 miniature designs, 4 stamps.—HARGER BROS., Settle, Yorks.

**Oxide of Copper**, 1s. per lb. Sample, by post, four stamps. Trade supplied.—NIROSI, Elswick-road, Newcastle-on-Tyne.

Orguinette **Music**, all the latest tunes. Price 1½d. per foot. Organina music. Orguinette, 30s. Lists free.—J. E. WOOD, 1 City-road, Finsbury-square, London.

**Violins**, selected Bavarian and French, 9s. 6d. and 15s. Half usual prices. Carriage paid on approval.—PAYTON and Co., Importers, 127, Essex-road, London, N.

**Trouser Lengths**, 5s. each. Cheap Cloth for Ladies' Dresses, Mantles, Boys' Suits.—HEWITT, 27, Winfield Mount, Leeds. Patterns free.

**Electric Depot**, 10, Deansgate, Manchester.—Electric Breast Pins, 25s. Electric Bells, 4s. Induction Coils, 8s.—MILLAR, Proprietor.

Special **Amateur's List** of Castings and Finished Parts of our Motors and Dynamos, 1 stamp.—CUTTRISS and Co., Leeds.

**Sheet-Iron Punchings** for laminated armatures.—CUTTRISS and Co., Leeds.

**Mushrooms.** How cultivated in France. Illustrated pamphlet, translated by permission, 7½d.—J. BEST, Clarence-place, Belfast.

**Electric Bell**, battery, push, and 20 yards wire, carriage free, 9s. 6d.—FRANKLIN.

**Invalid Set Bell**, battery, pear push, stained and polished, pine case, carriage paid, 10s. 6d.—FRANKLIN.

Wholesale **Bell and Battery** Maker, Indicators, Induction Coils, Carbons, Terminals, Wires, &c.—FRANKLIN. Volta Works, 41, Sherman-road, Reading.

**Electric Bells** at trade price: Metallic base, Platinum contacts, silk wire, post free 3s. 6d.—HARRIS and Co.

The **Phœnix Bell Set**, Bell, Battery, Push, and 12 yards double wire, post free 8s.—HARRIS and Co.

Set of **Castings** for Motor (Chaster's), 6s.—HARRIS and Co., 172, Railway-approach, Shepherd's bush, London, W.

**Edward W. Drury**, Hull, manufacturer of all kinds of glass bottles, wire, and Chemicals.

**Electrical Machine**, 38in. plate. Height, over 6ft. Very cheap. Photo sent.—MOODY BELL, Cheltenham.

**Catapults**, 7d., 1s., 1s. 2d.; elastic 2d., 3d. foot; square 1d. to 4d. yard.—MOODY BELL, Cheltenham.

**Mica**, otherwise Talc.—RICHARD BAKER & CO., 9, Mincing-lane, London.

Write for Hindle's **List** of Electrical Apparatus, free; all parts for amateur construction.—Irwell Vale, Helmshore.

**Dynamo** and other insulated Wires at wholesale prices. Reduced list free.—MAW, 8, Clayland-road, London, S.W.

**Gas Engines.**—1-man, £16; 1½-man, £20 cash, delivered, equal new, six months' guarantee.—BARKER, Scholefield-street, Birmingham.

**Microscopes and Apparatus.**—R. G. MASON (from J. Swift), manufacturing Optician to the trade; Binocular Microscopes, Stand, and Stage Condensers, Spot Lenses, Polariscopes, and other apparatus. Repairs and alterations. All kinds of mounting materials.—24, Park-road, Clapham, London, S.W.

"**See-saw**" **Waltz**, 4s.; reduced price, 1s. 6d. post free.—WILLIAM LEA, 50 and 52, Church-street, Liverpool.

"**Hypatia**" **Waltz**, 4s.; reduced price, 1s. 6d. post free.—WILLIAM LEA, 50 and 52, Church-street, Liverpool.

20s. worth of best **Songs and Pieces**, post free, 1s. 2d.—WILLIAM LEA, Church-street, Liverpool.

**Chemicals and Apparatus** at lowest prices. Stamp for reply.—GREENWOOD, Chemist, Lozells, Birmingham.

**The Comprehensive Astronomical Map**, containing the stars visible in Britain, with indicator. Paper, 1s. Cloth, with cases, 2s.—ARCHIBALD and PECK, Hanover-street, Edinburgh.

**The Kinetic Engineering Company**, 36 and 37, Brooke-street, Holborn, London. Circulars and list post free.

**Dynamo Wire**, 1s. 2d. per lb. Line Wire, 29s. 6d per mile. Pushes 4s. per dozen.—KINETIC COMPANY.

**Leclanche Cells**, best. No. 1, 16s.; No. 2, 19s.; No. 3, 22s. 6d. per dozen.—KINETIC COMPANY.

**Electric Bells.**—Best quality, workmanship, appearance, and value in market, 40s. per dozen.—KINETIC ENGINEERING COMPANY.

**Maiche Patent Battery.**—Best yet produced. Circulars and Scientific Reports post free.—KINETIC ENGINEERING COMPANY.

**Electrical Supplies** of all kinds.—KINETIC ENGINEERING COMPANY, 36 and 37, Brooke-street, Holborn, London, E.C.

**Brass Door Plate**, 9 by 4, engraved in any style 4s. 6d.—DEACON and SON, General Engravers, Ramsgate.

**Stammering.**—The "Luophone," a mechanical appliance singularly serviceable in overcoming this distressing habit, with instructions for use, 13 pence.—Mr. RYBOTT, Cliff-road, Southampton.

**Gas Engines**, simple, cheap, and reliable, ½ M.-P. to 1 H.-P.—W. and J. H. HILL, York.

**Roughened Glass**, a large quantity cut up to 24in. by 8in. by 3-16in. thick, been used. What offers? Cash required. JOB BLAIN, Carlisle.

**Motor Castings**, materials for Electric Bells, Batteries, Galvanometers, Intensity Coils, Microphones.—KING, MENDHAM, and Co., Bristol.

**Insulated Wire Table**, showing size, weight, resistance per foot, feet per ohm, &c., price 3d.—KING, MENDHAM, and Co., Bristol.

**Standard Ohm**, in box, copper poles, guaranteed correct to ten thousandth of ohm, 21s.—KING, MENDHAM, and Co., Bristol.

**Wimshurst Influence Machine.**—Sole Manufacturers of Improved Pattern. Numerous testimonials as to thorough efficiency.—KING, MENDHAM, and Co., Bristol.

**Galvanometer Cards**, improved for tangent and ordinary combined, 2½in., 8d.; 4in., 10d.; 6in., 1s.; post free.—As Above.

Write for **King, Mendham, and Co.'s** large new and reduced Price List, post free 4 stamps.

Improved half-horse **Water Motors**, suitable for driving amateurs' lathes; very strong; £4 10s.—MUNCASTER.

Complete set of **Castings** for above, including all bolts, shaft, &c., 37s. 6d. Litho and particulars, 6d.—F. MUNCASTER, 34, East View, Preston.

**Dynamo Castings** (Mr. Bottone's), 6s. set, comprising field magnets, armature, standard, brass armature plates, brushes, trunnions, and brass bearings.—E. and T. WIBLIT, 29, Loyd-street, Leeds, Yorkshire.

**Electric Bell**, 3s. 6d. Leclanche Battery, 2s. Bichromate, 3s. Ruhmkorff Coil, 6s. Other apparatus cheap.—BUNTING, Didsbury.

Model **Steam Engines** made or repaired. Separate parts fitted up, boilers made to order.—LUCAS and DAVIES, 21, Charles-street, Hatton-garden, London.

**Instruction in Glass-blowing.** Vacuum pumps, high vacua tubes to order.—H. NEWBOLD, 25, Calthorpe-street, W.C.

**Oxygen Gas**, compressed in cylinders, handiest and safest for limelight.—CLARKSON, Compressed Gas Chemist, Bartlett's-buildings, E.C.

**Oxygen Gas**, compressed into iron bottles, liquid nitrous oxide and carbonic acid.—CLARKSON, Compressed Gas Chemist.

**Oxygen Gas**, compressed into iron bottles; prices on application.—CLARKSON, 28, Bartlett's-buildings, Holborn, E.C.

Separate **Pedal Organs**, for harmoniums and American organs, from £3.—G. FRYER, 17, Richardson-street, Swansea.

**Engineer's Taps.**—¼in., 1s. 1d.; 5-16in., 1s. 2d.; 3-8in., 1s. 3d.; 7-16in., 1s. 4d.; ½in., 1s. 6d.; 5-8in., 2s. 0d.; ¾in., 2s. 6d.; 7-8in., 3s.; 1in., 3s. 6d.—JEREMY and SON, North-street, Stafford.

**Castings.**—Half horse-power, Vertical, Horizontal, or Launch Engine Castings, ports in cylinders. Complete sets Castings and Forgings, 12s. 6d. One horse power, 25s.—TOMLIN, Highfield-terrace, Barnsley.

**Castings.**—Bench Drilling Machine Castings, 3s. 6d. set. Small Brass Engine Castings, 2s. 6d. set.—TOMLIN, Highfield-terrace, Barnsley.

**Castings.**—Half horse-power, 9s. 6d. set, ports in cylinders, horizontal, launch, or vertical. Send for price list, designs and particulars of perfected castings, free.—I. TOMLIN, Engineer, Highfield-terrace, Barnsley, Yorkshire.

**French Polishing**, Staining, Varnishing, and Painting, 122 receipts or trade secrets, with full instructions and details, free 1s. (Genuine.)—I. TOMLIN, 28, Highfield-terrace, Barnsley, Yorkshire.

**Water Motors**, for sewing machines, organettes, window advertisements, 32s., 42s. List one stamp.—WHEELER.

**Fan Castings.**—Improved Registered Designs; sets 5in., 3s.; 6in., 4s.; 8in., 6s. Drawings, 4d.—WHEELER, Engineer.

**Water Motors.**—Complete one horse-power, £9. Half, £6. Quarter, £4. Eighth, £3.—THOMAS WHEELER, Preston.

Amateurs and the trade supplied with **Dynamo** CASTINGS and every description of wire for electrical purposes at lowest possible rate. Dynamo Castings machined and fitted ready for winding. Dynamo machines repaired.—ASHBY.

Gramme **Dynamo Machines**, sound and well made, suitable for lighting shops, &c. Expressly made for long running; long bearings, massive fields; 120 candle power, £6 10s.—A. ASHBY, 184, King's-road, Chelsea.

**Dynamo Wire**, 10 to 18, 1s. 6d.; 20, 22, 24, 26, at 1s. 9d., 2s., 2s. 3d. 2s. 6d. lb.—DARVILL, 8, Bient View-road, The Hyde, London, N.W.

**Piles.**—Spencer's Vegetable Pills are a certain remedy, prompt and safe in action, perfectly harmless. 1s. 6d. per box, post free.—S. SPENCER, 26, Dysart-road, Grantham.

Ward's new **Division Plate**. Enormous success. 360, 192, 170, 156, 112, 100, 38. Invaluable to engineers.

**Division Plate** for Draughtsmen, Surveyors, Bicycle Makers, Wheelwrights, Engine Dividers. Indispensable to all requiring precision, accuracy, speed.

**Division Plate.** Saves time, money, and temper. Buy one. Try one; 13 stamps.—WARD, Holcroft-terrace, Fulham

Second-hand **Dynamo Machines** for Arc or Incandescent Lighting.—Messrs. Paterson and Cooper, of 76, Little Britain, London, have several of these to offer at specially low prices. Particulars on application.

Model **Boilers**, from 7s. 6d. each, tin and copper sheet. List. stamp.—J. W. M., 41, Cross-roads, Upper Wortley, near Leeds.

**Fretwork Patterns.**—Given away to every applicant, some splendid patterns, 1 stamp.—S. Brockway, Marlborough.

"**Electrician,**" Vol. X. and XI., complete, clean, unbound; 'Cassell's Cities of the World," 30 parts, complete. Offers.—T. P., 1, Granchester-street, Newnham, Cambridge.

50in. **Bicycle**, nearly new, ball bearings, part bright, £7, a genuine bargain.—Richings, Market-square, Aylesbury.

2¼in. Wray **O.G.**, slow-motion, adjustable equatorial, £6.—Rev. Leighton, Worfield, Bridgnorth:

**Fretwork.**—14in. Fretwork Frame, twenty assorted patterns, twelve saws, bradawl, hinges, screws, 2s. free.—Wm. Ellicott, Launceston.

**Lawn Mower**, Green's patent, 20in., good condition, suit cricket grounds, £3 10s., or offers.—W. Hartnup, Hurst-green, Sussex.

Cox-Walker's **Incandescent Lamp-Holder**, new patent, highly approved. post free, 1s. 6d. stamps.—Harrison, Cox-Walker, and Co., Darlington.

**Square Holes.**—How to cut square holes by an ordinary hand tool in any lathe, included in our catalogue, 7 stamps.—Britannia Co.

**Specimen** of square 5-16th hole, cut in metal will be sent for six stamps.—Britannia Co.

**Sharpening Files** by simple chemical process at nominal cost. Having recently given five pounds, we charge 1s. for the receipt, including catalogue.—Britannia Co.

Catalogue of **Lathes** and of various Parts of Lathes, rough and finished, 6d.—Britannia Co., Engineer's Tool Makers, Colchester. Two Prize Medals, 1883.

New **Fret Saw** for advanced fret-cutters and cabinet-makers. The first lot will be finished in a few days. Takes 20 inches under arm. Price 55s.—Britannia Co., Colchester.

Special **Lathe**, 4ft. 6in. screw-cutting, with gear-cutting apparatus, for cutting wheels of any pitch. Having an order for one, we desire to take two other orders to economise cost of manufacture.—Britannia Company.

Very strong **Steel Springs**, from 5 inches to 2 inches wide, adapted for motor, and some gear wheels, various sizes. Send exact details of what you require.—Britannia Co., Colchester.

"**Lantern Manipulation,**" 3d. post, gives instructions, management, and making lime and oil lights.—Pumphrey, Stanhope-street, Birmingham.

10,000 **Lantern Photographs**, 6d. plain; 1s. coloured. List, 140 pages, facsimile illustrations, 100 sets, 6d. post.

**Pocket Tripod**, patent, for professionals and amateur photographers. cyclists. Particulars, illustrations, and testimonials to be had on approval.—A. Pumphrey, Stanhope-street, Birmingham.

**Lantern Readings** to 100 sets slides, with facsimile illustrations, 80 sets for 2s. 3d.—Pumphrey, Stanhope-street, Birmingham.

**Lathe**, bench, magnificent 3in. centre, with machine-cut back-gear and Universal compound slide-rest, division plate, and index point, steel conical mandrels, steel collars, slide-rest, is made so it can be removed from the bed without shifting the poppet, bright hand wheel, 2ft. 6in. planed gap bed, with bridge fitted, 2 T face-plates, driver chuck, bell chuck, and spanners, complete, brand new; will take for the above £5 15s., or with treadle and table wheel, and ready to work, £6 10s. lot.—R. Price, 102, Teviot-street, St. Leonard's-road, Poplar, E.

£15.—**Lathe**, 6in., 4ft. V and flat bed, slide-rest, chucks; a really good tool.—Address, Roberts, 46, Queen Victoria-street, City, E.C.

**Incandescent Lamp**, Battery, Chemicals, Wire, &c., in box, 2s. 6d. Carriage 3d. New.—24, Dean-street, Soho.

Leclanché **Batteries**, No. 2, 17s. 6d. per dozen, best make only; sample 2s. 6d. New.—24, Dean-street, Soho.

"**English Mechanic,**" 22 volumes, XI. and XIV. to XXXIV. not bound, Vol. XXXII., two numbers short; what offers?—Ravenscroft, Bolton-road, Small Heath, Birmingham.

**Mortising Machine**, perfect condition, cost £12. Price £5 10s.—67, Thomas-street, Aston-road, Birmingham.

10,000 **Missing Friends.**—A little Book with Photograph; send post card.—Fritz Camera, 41, High-street, Sydenham.

For sale, cheap, a good **Lathe**, by Holtzapffel, a quantity of various tools, several chucks, slide-rest, &c. Also large induction coil.—H. Thorpe, 85, Theobald's-road.

**Microscopic Slides**, a valuable collection, 7s. dozen Two samples, 15d. free.—Tylar, 33, Geach-street, Birmingham.

Remington **Type Writer**, in thorough order, cost £25, price 5 guineas.—S., 20, Montpelier-road, N.W.

Dollond **Telescope**. 4in., quantity apparatus, cost £75. Price £21.—S., 20, Montpelier-road, N.W.

**Building Paper**, light, cheap, waterproof, 40in. wide, 2d. yard, 10 yard rolls; sample roll, parcel post, 2s. 6d.—Chemical Papers Co., Limited, Lombard-court, London.

Albion **Printing Press**, folio foolscap, perfect, £6.—Francis, Rochford, Essex.

**Photo-chromoscope**, £5 and £3, as new, half-price, splendid effects for lantern slides.—Francis, Rochford, Essex.

**Melodium Organ**, 8 tunes, fine and powerful tone, 28in. by 14in. by 14in., as new, £3 10s.—Francis, Rochford, Essex.

**A Practical Engineer and Machinist's** Drawing Book, calf bound, covers little soiled by damp, cost 62s., price 25s.—J. H. E., 12, Rhys street, Trealaw, Glam.

Nearly all brass Horizontal **Engine**, 1¼ bore, 2in. stroke, in working order, 15s.—J. H. E., 12, Rhys-street, Trelaw, Glam.

Hardy British **Ferns**, including Aspleniums, Lastreas, Polypodiums, Athyriums, Polystichums, Cystoptera, Blechnums, 15 free 1s 3d. Twenty large Rockery Roots, 2s. Fifty, 4s. 6d. 100, 8s. Botanically named. Carriage paid.—John Burns, Fellside, Kendal, Westmoreland.

Choice **Alpine Auriculas**. Excellent strain. Large Flowering Plants, 2s. per dozen, free.—John Burns, Fellside, Kendal.

**Photography.**—Half-plate Camera, 7s. 6d. Lens, 12s. 6d. Also stand, double back japanned cases for plates, dishes, &c. Must be cleared.—A. Chambers, London-road, Ore, Hastings.

20 candle-power **Dynamo**, worth £4, offered for £2 10s. Real bargain.—Address, A. Hetherington, Claybrooke-road, Fulham.

Model **Engine Castings.**—Horizontal, Locomotive, Vertical, Beam and Marine. List, stamp.—Wood, Dalley-street, Broughton, Manchester.

Patent Spiral Grip **Letter Racks**. "An invaluable invention." Parcels post, 1s. 3d.—Iles, Highgate-street, Birmingham.

**Tricycles**, Bicycles, Safeties. Large discount. Write early stating requirements.—J. Argent, 6, Clarendon-street, Bradford, Yorks.

**Colonel Ross's** condensing **Smoke Filter Pipe**, forwarded for 2s. 2d. by his agent.—G. Hester, Tobacconist, Richmond.

Large Astronomical **Telescope**, 4½in. o.-g.. 5 eye-pieces, massive garden tripod, £21.—3, Essex Villas, Fillebrooke, Leytonstone.

Four achromatic **Microscopic Objectives**, 1in., ⅔, ½, ¼, 50s. Polariscope, with selenite, 15s.—99, City-road.

Strong 1 H.-P. **Engine and Boiler**, £6; 6ft. shafting, 3ft. and 1ft. wheels, 50s.—99. City-road.

**Battery**, bichromate, highest electrical efficiency, Contains 10 per cent. more chromic acid than potash bichromate, Lee's new double Bichrome. Soluble in own weight water. 7d. lb., 7lb. sample parcels. 6½d. lb. in 56lb. lots.—R. A. Lee.

**Wire**, double cotton-covered, No. 8 to 18, highest conductivity; 2s. per parcels post, lb., free; ditto, 18 to 22, 2s. 3d—R. A. Lee.

Chaster's **Electro-Motor** (Registered), as described in English Mechanic, Nos. 1026, 1027, 1029, and 1041; price £4.—R. A. Lee.

Chaster's **Electro-Motor.**—By special permit, R. A. Lee supplies carburetted annealed castings of above, 3s. 6d. set.

Chaster's **Electro-Motor**, planed. bored, and turned throughout, including wire and all materials; price £2.—R. A. Lee.

**Dynamo Machine**, 20-light, continuous working, patent disc armature, low speed, requires ¼-h. to drive, £15.—R. A. Lee.

**Electro-Motors**, Batteries, Dynamos. For Lee's other electrical specialities, see advertisements last week.—R. A. Lee, 76, High Holborn, London.

**Photographs.**—12 Carte-de-Visite, Royal Family, Eminent Men, Actresses, and Comic, 1s. 2d. 12 Cabinet ditto, 3s. 6d.—B. M., 76, Theobald's-road, London, W.C.

**Universal Trade and Amateur Supply.**—Lecture requisites; light, heat, air, water, geology, engineering, chemistry, photography, &c. Wholesale and export.—Caplatzi.

**Astronomy.**—First quality O.G.'s in cells, warranted, 3in., 50s.; 3¼, 70s.; 3½, 100s.; 4in, 180s. Unrivalled for prices.

**Achromatic** 2½, 45in. tube, good stand and case, 50s. Stands alone, 20s Astronomical Clock Movement, 60s.

**Tubes.**—5ft. metal, for 4in., with cell, rack, eyepieces, 40s. Various smaller; Altazimuth Stand, Heads, Finders.

**Photography.**—Heap of Apparatus of all kinds. Good ½ Lens, 5s. ¼, 12s. Excellent Stands, Baths.

**Catalogue, 2d. Caplatzi, Science Depot, Hire and** Exchange, Chenies-street, Tottenham-court-road, near British Museum.

**Stocks and Dies**, Whitworth, or Gas, Wonderful Tools; List free.—F. M. Rogers, 21, Finsbury-pavement, E.C.

**Books.**—"Mechanic's Workshop Companion," 5s. 6d.; "Engineer's Machinist's Practical Assistant," 2s. 9d., per post.—E. F. Baldwin, Robinswood-hill, Gloucester.

Steel **Name Stamps**, 2d. per letter. Figures (set), 2s. 4d. Letters, 6s. 4d., per post.—E. F. Baldwin, Robinswood-hill, Gloucester.

**Name Burn Brands**, 5d. per letter. Indiarubber Name Stamps, 1s. 8d. per post.—E. F. Baldwin, Robinswood-hill, Gloucester.

**Gas Engines**, 1, 2, and 4-man. Simple and strong. Numerous references.—Ellis Butterworth, Rochdale.

Superior **Engine Castings**, all brass, horizontal slide valve, ¼in. bore, 1in. stroke, 2s. 3d. Boring and turning cylinder, 7d.

¾ bore, 1½in. stroke, 3s. Boring and turning cylinder, 10d. This size and upwards have parallel guide bars.

1 bore, 2in. stroke, steam ports made, 5s. Boring and turning cylinder, 1s., postage extra. Stamp for reply.

1¼ bore, 10s.; 1½in. bore, 13s. Post orders preferred.—S. Cookson, Ravenscliff road, Kidsgrove, Staffordshire.

**Recipe** for mixing all kinds of Paint, quick-drying colours. Varnish colours, oil colours, &c., 15 stamps.—F. Taylor, 6, Canterbury-street, Hill Fields, Coventry.

**Ventriloquism.**—How to acquire this wonderful art. Success certain. Never fails. 7 stamps.—See below.

Fac-simile **Printing Press**, how to make; print hundreds of one copy. Costs few pence. 7d.—See below.

**Recipe** for Self-shining Waterproof Blacking, 7 stamps, genuine and inexpensive.—See below.

**Recipe** for Rubber Stamps. Simple and costless, 7d. All four, 1s.—G. Marquis, Allhallowgate, Ripon.

**Formulas Worked Out** for winding Dynamos and motors from 10 c.-p. to 500 c.-p., 14 stamps. Drawings and Diagrams from 5s.—H. Jones.

**Dynamos**, patent improvements, No. 2,122. 70 c.-p. machines, £5. 32 volts, 7 ampères.—H. Jones.

**Dynamos**, best small machines in the trade, and cheapest double-covered Wires to 20 gauge, 1s. 8d. lb.—H. Jones.

**Motor Castings** (model 5-light dynamo), laminated armature, 20 per cent. better than solid. 3s. a set.—H. Jones.

**Dynamos** for Home Lighting.—5 lights, or arc of 500 c.-p. Price £6 10s., approval. Warranted.

**Dynamo Castings**, with laminated armatures, 8 c.-p., 5s.; 16, 5s. 6d.; 20, 6s. 6d.; 30, 7s. each.—H. Jones.

**Dynamo**, laminated armatures, no heating, ventilating; 70 c.-p., 16s. a set; finished, £5. Warranted.—H. Jones.

**Dynamo Machines Repaired**. 100 c.-p., 9s. Motors, with wire, 5s. 6d.—H. Jones, 48, High-street, Lambeth, S.E.

**Incandescent Carbon Lamps**, low resistance, 3s. each; Fairy Lamps, 3s. 6d.; Platinum Lamps, 1s. 3d., post free.—Todd, 14, Wentworth-road, Manor Park, Essex.

**Incandescent Lamp Holders**, new pattern, best in the trade, 12s. dozen; sample, post free, 1s. 3d.—Todd, as above.

**Microscopic Objects.**—Small collection to dispose of cheap.—Particulars, W. White, 17, York-street, Nottingham.

Great Bargain.—Three-man **Gas Engine**, faultless; guaranteed perfect.—Smith, Higginshaw Post Office, Oldham.

Tudsbury and Sons' "High Tension" **Wimshurst** Machines, with their new compound ebonite plates, more powerful than glass, unbreakable. Price, 16in., 65s.; 12in., 48s.; 8in., 20s. List, one stamp.—Edwinstowe, Newark.

Hand **Drilling Machine**, drills ⅜ holes 6 inches from edge, 25s.—S. Beeching, Mareham-le-Fen, Boston.

**Bijou Stove and Quart Kettle**, most portable made, 18 stamps.—Shaw, 76, Harrogate-road, Hackney, London.

**50in. Club**, ball pedals, in first-class condition, £5.—Wray, North hill, Highgate.

Screw-cutting **Lathes**, 5½in. and 6in. centres, £13 and £16 each.—79, Dudley-road, West Bromwich.

**Am-meter**, calibrated to 20 ampères, for amateurs, 6s. 6d.—W. A. Walton, London-road, Gloucester.

**Steam Canoes**, with machinery complete, from £30. Photo, 4 stamps. Send for particulars.—Chenhall, Eastville, Bristol.

**Engine and Boiler** combined, vertical, 4-horse, complete, £36; a bargain.—Rigby Smith, Fazackerley, Chorley.

**Pocket Knives.**—Mechanics requiring good useful knife, 15 stamps, to W. Belk, 13, Bradley-place, Grammar-street, Sheffield.

For sale, **Telescope and Stand**, with brass fittings, object glass 3in. diameter. Price, £4 10s. Maker, Slugg.—19, Ellesmere-street, Moss Bank, Higher Crumpsall, Manchester.

To Boaters.—**Canoe Gas Engine**, generates its own gas. Castings, 50s. Drawing, 5s. Litho, 3 stamps.—A. Dorrington, West Gorton, Manchester.

**Working Plan and Details** of Canoe suitable for the above engine, 5s. Litho, 3 stamps.—A. Dorrington, West Gorton, Manchester.

The Amateur's **Gas Engine Castings**, 42s. Working Drawing, 5s. Litho, 3 stamps.—A. Dorrington, West Gorton, Manchester.

**Drilling Machine**, self-acting feed motion. Castings, 7s. 6d. Forgings, 5s. Drawing, 18 stamps.—A. Dorrington, West Gorton, Manchester.

Half horse-power Horizontal **Engine Castings**, ports in cylinder, 12s. 6d. Drawing. 18 stamps. Litho, 2 stamps.—A. Dorrington, West Gorton, Manchester.

Launch **Engine Castings**, 2in. cylinder, 12s. 6d.; 3in., 26s.; 4in., 50s.; 5in., 70s. Litho, 3 stamps.—A. Dorrington, West Gorton, Manchester.

A nearly new portable **Wooden Building** for sale, 13ft. long, 9ft. high, 8ft. wide; could be used for a workshop or coachhouse, price £10.—W. Cobb, 300, Mile End-road.

## Wanted.

Old **Microscopes**, by Adams, Amici, Baker, Dollond B. Martin, Pritchard (Goring's "Engiscope"). Varley, and other old makers.—J. Mayall, Junior, 224, Regent-street, London, W.

Wanted, piece of well-seasoned Straight-grained Greenheart, 7ft. long by 3in. by 1½in.—Price to J. S., Holly Bank, Budleigh Salterton.

Wanted known, Capps, Engineer, Hop Exchange, Southwark-street, S.E., is London Agent for Morgan's Boiler Compound.

Wanted, good second-hand Foot Lathe, 5in. or 5½in. centre gap-bed, screw-cutting.—Capps, Hop Exchange.

Wanted, second-hand double-action Steam **Pump**, about 4in. steam, 2½in. water.—Capps.

Wanted known, Bailey's Sight Feed Lubricators supplied and fixed by Capps, Engineer, Hop Exchange, Southwark-street, S.E.

Wanted, several gross of small Glass-stoppered and other bottles. Send wholesale list.—Harding, 196, Holloway road.

Wanted, Slide-rest for 9in. Lathe, Stocks and **Dies**, large size.—Hy. Walker, Cliff, Whitby.

Wanted "Dictionary of Mechanical Movements," also 4in. compound slide-rest, cheap.—Griffith, Llansannor, Cowbridge, Glamorgan.

Modern Tricycle, good, nickelled and enamelled, no objection to Coventry, £8.—H. Woodville, Abbey-road, St. John's Wood, London.

Deer Horns Wanted.—M. Day, Hook and Handle Manufacturer, 56, Driffield-road, Old Ford, London.

Wanted, "Miller's Chemistry," Vol. II. "Roscoe and Schorlemmer," 1 and 2, "Bloxham's Laboratory Guide," "Tyndall Sound and Heat."—H., 174, Charrington-street, N.W.

Wanted, Vertical Boiler, internal firebox, about 2ft. 6in. by 4ft. high.—R. Chaplin, 61, Spring-gardens, Doncaster.

Wanted, Lancaster's ½ plate Instantograph, or Meritoire, Chemicals, Apparatus; cash; approval.—C. J. H. Hamilton, Marle-hill, Godstone Station, Surrey.

Wanted, strong Iron Pedestal, with heavy many-grooved flywheel, treadle, &c.—H. Parson, The Firs, Guildford.

Wanted, Astatic Horizontal Detector, "Maxwell's Electricity." and books on Thermo-Chemistry.—J. S., 41, Manor-road, Brockley,

## Addresses.

Address wanted.—Makers of Firework Tools of every description.—Taylor, Milbourne-street, Blackpool.

To "Walsrek."—"Yesallaw."—G. BILLINGTON, 23, Falkner-street, Liverpool.

## A STANDARD METHOD OF TESTING AND RATING STEAM-BOILERS.

THE economical efficiency of a steam-boiler is of as much importance to a steam-user as the indicating of the engine, and the American Society of Mechanical Engineers is doing good work by endevouring to bring about a recognition of a "standard method" of trial that will determine the steaming capacity of boilers under any given set of conditions. It is not quite so easy a matter as it may at first thought seem, to accurately test the economical efficiency of a given boiler; but so much has been done in this country, in the way of elaborate trials, that, if everything is straightforward, there is no room to doubt the correctness of the results obtained. Still, much diversity in practice prevails in this country, and, except amongst scientific engineers, we may be sure that in the United States the diversity is greater still. The object of the American Society of Mechanical Engineers was to give some system of testing a sort of authoritative stamp, and they therefore appointed a committee to frame a code of instructions, which, if carefully followed, would enable any fairly skilful engineer to obtain all the facts needed for ascertaining the economical efficiency of a steam-boiler with substantial accuracy at the least possible expenditure of time and money, and also without the use of any special apparatus. This committee consisted of W. Kent, J. C. Hoadley, R. H. Thurston, C. E. Emery, and C. T. Porter, and, experts as they are, they found some difficulty in reconciling the opposing views of recognised authorities; but as their object was not to devise a system giving results exact to the degree necessary in purely scientific work, they have carefully considered the advantages and disadvantages of various practices, and have formulated a code which may be relied upon for giving the substantial accuracy which satisfies the commercial requirements of the steam-users. At the same time they have presented their view of the recent refinements, which will be useful to engineers who wish to obtain results of the utmost possible completeness and scientific exactitude. So far as the commercial considerations are concerned, the purchaser of a steam-boiler wishes to know with precision the quantity of steam that a generator can supply continuously under prescribed conditions; what is the state of the steam, and what amount of fuel is consumed in producing it. He also wants to know what is the character of the combustion, and the actual conditions of operation for the boiler to do its best. It is clear that before a purchaser can expect to obtain the kind of boiler he requires, he must definitely state the conditions under which it is to be worked; then the engineer from previous experience can determine the size and pattern that are most likely to yield satisfactory results; but when the boiler is set and ready to proceed with its work, it is advisable to make a trial of its economical efficiency, and if all the necessary data are provided with tolerable accuracy, then we know that it should be as efficient at any future period, or some alteration has occurred which renders the generator less economical. It follows, then, that the trial of a steam-boiler should be made with every precaution to prevent errors in weighing-in coal and measuring water, in observing the state of the fire at the commencement and end of the trial, in noting the state of the steam, and in testing the temperature and composition of the escaping gases. In tests made in earlier times, the coal consumed was frequently estimated, on the well-known "near enough" principle, and as no one thought it necessary to look to the state of the steam, it is easy to show, if one believes implicitly in old reports, that our modern boilers are not so efficient as some of those made half a century ago. We know, however, that these old reports are altogether untrustworthy, for some of them actually give an evaporative efficiency higher than is theoretically possible. Nowadays we know that it is not possible to test a boiler on all points at once. Maximum steaming capacity and maximum economy of fuel consumption cannot be tested at the same time, and it is necessary, therefore, in any trial to state the object, and to keep that object in view during the whole time the trial lasts. It is advisable, too, to measure the boiler exactly, to facilitate subsequent calculations, and also to detect defects in construction or in the arrangements of the setting. The fuel to be used must be decided upon, and if its composition is not known an analysis should be made. The instruments should be inspected and standardised, for upon the accuracy of their work the whole trial depends. Scales and weights are easily tested; but the thermometer, barometer, and gauges should be standardised before and after the trial, while the apparatus used in connection with the calorimeter for determining the quality of the steam demand exceptional care, and even when of sufficient delicacy and accuracy, a mean of several observations must be taken to obtain a result within reasonable limits of error. The trial should be carried on for at least 10 hours, and during the whole time the utmost uniformity in the conditions should be preserved. For that reason the committee are unanimous in recommending that graphical methods of recording the conditions should be adopted wherever practicable. They also attach much importance to the method of starting and stopping the trial; so much, indeed, that they suggest an alternative method in case the first may not be practicable. In the "standard" method steam is to be raised to the working pressure, and the fire drawn as rapidly as possible, the ashpit cleared, and a new fire with the weighed fuel started, noting the time and the height of the water-level just before lighting the fire. At the end of the test the fire is to be drawn, the grates and ashpit cleared, and the water-level observed when it is in a quiescent state; it should be, if possible, the same as at the start; but if not, the difference must be noted and a correction made by computation, not by operating the pump. The pressure of the steam is to be kept as near as possible to the average during the trial by regulating the discharge by means of the stop-valve while the fires are being drawn. It will be seen that there are decided objections to this method, and the alternative provided by the committee will satisfy most experts. Instead of drawing the fires, they are to be allowed to burn low, and are then thoroughly cleaned, when the amount of coal on the grate is estimated as nearly as may be. When everything is straightforward, it is easy to contrive to have about as much fire on the bars at the end of the trial: at all events, no very serious error is likely to creep into the results by the adoption of the simple "alternative" method of the committee. The amount of fuel being estimated—it is usual to level the burning coal and estimate it as thickness of fuel,—the pressure of steam and height of water-level should be noted, and the time entered as the point of starting. The weighed coal is now fired, and the ashpit cleared. As the end of the test approaches, the fires should be cleaned so as to have about the same thickness as at the commencement and the same condition, the pressure and water-level should be brought to the point they were at when the start was made, and the time of the end should be noted. The boiler should be run continuously without stopping for meal times, or in consequence of any rise or fall in the pressure due to the demand made by the engine. The pressure should be kept as uniform as possible; but in case it rises above the desired point, an extra outlet should be provided, fitted with a stop-valve, so that steam can be released when necessary. When the boiler is connected with others—that is, delivers its steam into a main pipe—the committee suggest that the safety-valve on the boiler being tested should be set to blow-off at a few pounds higher than the valves on the others, so that in case of a rise in pressure above the limit, the valves on the other boilers will lift and relieve the excess of pressure without necessitating any interference with the damper or fire of the generator under test. As to that, it would be better in every way to temporarily disconnect the experimental boiler, and even waste the steam, for the trials are to be of such value that the mere loss of fuel during a ten hours' trial is as nothing to the economy which is to be effected in the daily working of the boiler. The committee recommend that the boiler should be worked for a week before being tested, in order to dry the mortar of the settings and thoroughly heat the walls and chimney; then, if steam is got up a few hours before the trial, the conditions so far will be suitable for obtaining a fair test of the evaporative efficiency of the generator. We need not, however, dwell on these simple conditions, for they are well understood, and are, at least, in this country, almost universally secured when tests of boilers are made; but the object of the committee is to establish some definite value for "the unit of evaporation," and to determine what shall be considered a "commercial horse-power," so that purchasers may know exactly what is meant when a boiler is said to be of such and such power. After a careful consideration of this matter, the committee recommend that the "unit of evaporation" be considered as one pound of water at 212° Fahr. converted into steam of the same temperature, which is equivalent to the utilisation of 965·7 British thermal units (B.T.U.) per pound of water. The relative economy of the boiler would then be expressed, as is now customary in this country, by the number of units of evaporation obtained by the combustion of one pound of fuel. That is a definite, easily-understood datum; but the unit to be chosen to express the "power" of the boiler is not so easily settled. On this point the committee say that since the boiler is simply an apparatus for the generation of steam, and since the province of the steam-engine is to develop power from that steam by the conversion of heat into mechanical energy, and since, furthermore, the engine develops power with a degree of efficiency which may vary enormously with differences in construction and operation of that machine, it cannot be properly said that we have any natural unit of power for rating steam-boilers. They think the most nearly scientific system of power-rating yet proposed is that which considers the power of a boiler to be that expended by it in driving out all the steam which it makes against the pressure of the atmosphere—simple evaporation that is,—but that system does not meet the wants of engineers. What is wanted is a standard unit of boiler-power which may be used commercially in rating boilers, and in specifications prescribing the power demanded by the purchaser and guaranteed by the vendor. It is obvious that there are almost insurmountable diffi-

culties in determining this point, and the best that can be done is to assume a set of practically attainable conditions under which it would be fair to assume that any boiler can be worked in average practice, and to take the power so obtained as the measure to be used in commercial transactions and engineering calculations. The unit which has been most generally used is the weight of steam demanded per horse-power per hour by a fairly good engine; but that weight has been gradually decreasing since the time of Watt. Good average engines of the non-condensing type use 30lb. of dry steam per horse-power per hour, while large engines with condensers use from 20 to 40 per cent. less. The committee determined to adopt 30lb. of steam as the unit, and as the conditions under which it is generated and used must be taken into account, they finally resolved that the unit of boiler power should be 30lb. of water evaporated per hour from a feed-water temperature of 100° Fahr., under a gauge-pressure of 70lb., which shall be considered equivalent to 34½ units of evaporation—that is, 34½lb. of water evaporated from feed at 212° Fahr. into steam of the same temperature. The committee consider that any boiler rated by the above unit should be capable of developing its stated power with easy firing, moderate draught, and ordinary fuel, while exhibiting good economy, and should at the same time be capable, on emergency, when maximum economy is not the object aimed at, of yielding at least one-third more than its rated power. The Committee have obviously brought a good deal of skill and thought to bear on the question, and it is for the advantage of all interested that a standard method of rating both engines and boilers should be adopted and recognised by the trade and the profession.

## THE AMATEUR WORKSHOP. — V.

### Planing Machines—Driving Gears.

In this hand machine I propose to drive the table by a pinion gearing directly into the rack, and actuated by a cross. I choose this because it is the easiest method of construction; but I shall also describe a train of gearing having fast and loose pulleys for a power-driven belt. But before doing so it will be well to enumerate some of the ordinary methods of driving planing machines.

These differ in regard to the mechanism employed, but for the most part they are designed with the purpose of bringing the table up to the cutter at a rate proportioned to the cutting capability of the tool, and taking it back with as little loss of time as possible. A heavy table is made to travel more slowly than a light one, but the feed of the tool is made greater. The forward travel of an ordinary machine takes place at a rate of about fifteen feet per minute, but the usual rate of the return stroke is from two and a half to three times that of the forward or cutting stroke. The exceptions to this practice are the screw-driven machines, with reversible tool boxes, which permit of cutting in both directions, and some few machines of the smallest class which are driven by crank or disc arrangements.

These variable rates of travel are provided for in the majority of ordinary machines by a train of gearing similar to that illustrated in Fig. 39. In such an arrangement a single driving belt always drives in one direction; hence it becomes necessary not only to vary the rates of backward and forward travel, but also to provide for the reversal of motion without changing the direction of the belt.

In the figure the wheels for forward motion are all marked F, and those for backward B, and the arrows indicate the direction of rotation, those for forward being drawn in full lines, and those for backward in dotted outline. The driving pulleys are two in number, the central one being merely an idle pulley to carry the strap when the machine is not in motion. The shaft to which the inner pulley is attached, and which drives the wheel *k*, is made hollow to allow of the shaft of the outer pulley passing through to the wheel *c*, Fig. 40. The idle or carrier pulley *m* runs loosely upon this smaller shaft. The driving therefore, is effected as follows :—

The outside pulley *a*, for the forward motion, being keyed directly on the shaft *b*, drives wheels *c*, *d*, *e*, *f*, *g*, and the rack *h*. The inner pulley *i* being keyed on the hollow shaft *j*, which runs loosely upon the shaft *b*, drives wheels *k*, *f*, and *g*, and the rack *h* for the backward or quick-return motion. The proportions of the wheels are calculated for the difference in speeds, and if wheels *e*, *k*, and *c* are all of the same size, it is obvious that the wheel *d* alone produces the difference in the rates of travel, and to treble the speed this should contain three times the number of teeth in *k*, or *e*, or *c*.

Commonly the wheels *d*, *e*, *g* are within the framing of the machine, and the others, *e*, *k*, *f*, with the pulleys, on the outside. In some instances, however, the wheels of machines of medium size are compactly arranged on the outside of the framework, the rack pinion alone being within the bed. Fig. 41 shows such an arrangement with the indicative letters and arrows placed as in the last illustration.

A different train is shown in Fig. 42. Here the forward pulley *a* drives shaft *b*, wheel *c*, the idle wheel *d*, the wheel *e*, and pinion *f*, which last gears into the rack. The backward pulley *g*, keyed on shaft *h*, drives pinion *i*, wheel *j*, and rack pinion *f*, and the difference of speeds is due to the difference in the ratios of the pairs *i* and *j*, and *e* and *e*; the idle wheel *d* of course counting for nothing in the velocity ratios.

These spur gears are used in almost all machines of large and of moderate size. But there is one type of large machine, the invention of Sir Joseph Whitworth, in which there is no spur gearing and no provision for quick return. In these the table is driven by a longitudinal screw running underneath it, and since this screw is actuated by bevel wheels of equal sizes, Fig. 43, and therefore travels at an equal rate in both directions, the tool box is made to reverse, and the cut is taken on each traverse of the table. An automatic arrangement of cords whisks the box round at the end of each cut, hence the term "Jim Crow" applied to these machines by the workmen.

Frequently however, the driving screw is retained while the tool box remains stationary, and then bevel wheels of unequal diameter are employed, as shown in Fig. 44. In these the forward or cutting stroke is given by the pinion *a* gearing into the large wheel *b*, the backward or quick return by the pinion *c* gearing into the smaller wheel *a*. The bevel gear arrangement is also applied to small machines, and is likewise a very favourite method of converting hand planers into power-driven ones. Fig. 45 shows how differential bevel gear is applied to small rack planing machines.

Again there are cases where the quick return is provided for apart from cog wheels by making a difference in the relative diameters of the driving or of the driven pulleys, the gearing for backward and forward motion (either by cog wheels or by a screw) remaining the same. An open and a crossed belt are then necessary for reversing the table (Fig. 46.)

Fig. 47 shows an arrangement of gear in a *small* power driven machine which has no quick return, and Fig. 48 illustrates the old-fashioned chain gear. The wheels in the latter (not shown) are similar to those of an ordinary machine, but the chain has yielded to the more modern rack and pinion.

In the vast majority of planing machines, the work is travelled by the last pinion in the train of gearing, engaging with a rack fastened to the underside of the table. The racks may be single or *double*, or alternate, or stepped, and their teeth may lie upwards, downwards, or sideways. A single rack is shown in Fig. 49, a double and alternate rack in Fig. 54, a doubly and trebly stepped in Figs. 50 and 51. The Fig. 49 illustrates the rack which when bolted to the underside of the table will have its teeth pointing downwards, which is the usual custom. Fig. 52 shows one whose teeth occupy the reverse position, while Fig. 53 indicates the vertical form, shown also in Fig. 47. For this last arrangement there may be some reason in the case of machines where the table slides against vertical guide faces; but I can see no advantage in its employment for ordinary machines.

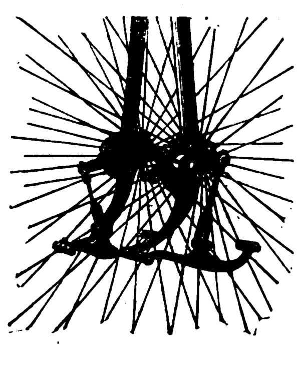
There is a decided advantage, however, in the employment of the rack in Fig. 52 where small machines are concerned. The tables of these are apt to lift, especially when made with flat bearing faces, or with double vee's. With a badly made pinion and rack the danger of lifting is increased, and with bearings worn loose, the pinion teeth may even ride over the points of the rack teeth, and either break the tool or injure the work by the upward jerking of the table. But with the inverted rack the table cannot rise at all, since the tendency is to pull it down upon its bed. In the heavy machines there is no risk of lifting occuring, and in these therefore the rack is downwards.

The use of a rack and pinion in the ordinary form having been objected to on the ground that it produces a ridged and wavy surface upon the work, various devices have been employed with the object of getting rid of this, as, for example, the screw-motion noticed above. One device consists in the employment of two racks placed side by side (sometimes united in one casting) in such a position relatively to each other, that the teeth of one come opposite to the tooth spaces of the other. (Fig. 54.)

The stepped racks (Figs. 50, 51) embody an extension of this principle. It is the slicing of the tooth width into short lengths and placing them one behind the other, the relation between the number of slices and the pitch being proportional. Thus if the breadth of the rack were divided into four parts and the pitch were 2in., each slice would be $\frac{1}{4}$ of 2in. = $\frac{1}{2}$in. behind its fellow. The idea of such a modification of the ordinary tooth form originated with Dr. Hooke in the 15th century, and singularly enough is now, in an improved shape, coming into general use in the helical form of tooth. Dr. Hooke's idea in stepping the teeth of wheels was to diminish the wearing of the tooth flanks and to insure greater uniformity of motion, for evidently the division of the breadth of the wheel teeth into numerous parts or sections insures the constant change of the parts in contact, so that the rubbing action is exchanged for momentary contact only along a succession of narrow faces.

## THE FACILE BICYCLE WITH SPEED GEAR.

To oblige some of their customers, Messrs. Ellis and Co., the makers of the now well-known Facile, who have recently removed to 47, Farringdon-road, have fitted specimens with a speed gear as shown in the illustration. The proportion adopted is as 4 to 5, so that a 40in. wheel will run as a 50in., and on the path or a good road, with a strong rider, the geared Facile will probably be found a trifle faster than the ordinary make, in spite of the additional weight and extra friction. A higher gear can be had if desired, and as not a few riders prefer the heavier and slower foot-action to the lighter and quicker motion of the ordinary Facile, the arrangement will probably meet their views; but it should be stated that the manufacturers have no intention of stocking the machine, as they consider that for the average rider and for general road work the Facile without gear is to be preferred. The illustration explains itself.



## PHOTOGRAPHIC BLOCK-PRINTING PROCESSES.

The announcement that an international competition between the operators with the new methods of automatic engraving is to be held this year (see p. 538, last vol.) lends an interest to the following patents which have been recently completed. The first relates to the invention of a veteran in the art, Mr. W. B. Woodbury, and refers to methods for producing blocks by means of photography, from which prints may be obtained in the ordinary press. Several processes of the kind are now employed with more or less (generally less) success, and the invention relates to improvements on these methods. The qualities necessary in a surface printing block produced from photographic pictures have usually been obtained by breaking up the continuous half-tone of the negative or positive into a series of lines, dots, or grains similar to the impression obtained from a lithographic stone. Mr. Woodbury first makes a series of negatives or positives from such objects as fine-ruled lines, netting, gauze, dots, or a print from a plain stone, which he uses as "resists" from which to make in the ordinary way what is known as a carbon transparency for transferring to the negative or positive, and then washing away the soluble portions. Sometimes he uses a photo-lithographic transfer, which is applied to the negative or positive, and if sufficient density is not obtained, he dusts bronze or other opaque powders over the image. In another method, in which he employs what is known as the dusting process, he coats a sheet of glass with a compound of gelatine or albumen, grape sugar, and bichromate of potash, and after exposure under a negative or positive, sifts over it suitable granular powders, or the material used for flocking paper, thus producing a grain negative or positive suitable for the purpose, or a negative or positive being coated with the solution, is treated in the same way as plain glass. Sometimes, by means of the Woodbury process, he makes a relief image from the combination of negative or positive and any of the various resists mentioned, and having obtained a suitable relief image by any of the above mentioned processes, by rolling or other convenient pressure, makes a reverse relief of the same on a sheet of fine card-board to which has been attached a sheet of transfer paper, and this image being inked over carefully with an ink roller and (after detaching the transfer paper, which may be temporarily attached to the card by means of indiarubber solution) is transferred in the ordinary way to zinc or other metal material for etching or to stone for lithographing. Another process which it would appear is applicable to almost any metal, has been recently patented by Mr. J. Brown, of Halsey-street, Chelsea. The patentee having selected a drawing, print, engraving, or photograph which it is desired to reproduce on a flat or other surface of steel, iron, copper, zinc, brass, bronze, and the more precious metals, prepares a solution of suitable gum, to which is added bichromate of ammonia or potash, in the proportions, for example, of about two parts of gum to one part of bichromate of potash or ammonia; these quantities varying in accordance with the temperature at the time of operating. In some cases it may be advantageous to add albumen, or fine soap, in the proportion of about 5 per cent. to the other ingredients. The solution is then applied to the surface of a plate or cylinder of metal, and the selected drawing or photograph is placed face downwards on the sensitised surface, and submitted to the action of light. By this means the image is imprinted on the sensitised surface of the gum sensitiser on the plate. The patentee then proceeds to develop the picture by means of a dabber or roller with a bituminous or acid-resisting varnish; after which the plate is immersed in a bath of spirits of wine or methylated spirit, which has the effect of disintegrating all those parts that have not been affected by the light, whilst hardening or coagulating those parts that have been so affected. The plate in this condition is ready for the action of the various mordants to which it is submitted, which may be either electric action, or any acids ordinarily employed, and suitable to the metal to which they are applied, the action of the mordant being allowed to operate until the requisite depth has been bitten into the plate.

In another process patented by M. L. de Roux, of Bègles, near Bordeaux, a positive taken from a negative in the usual way, is placed upon carbon paper, which has previously been dipped in a bath containing water to which four per cent. of bichromate of potash has been added. The positive and the carbon paper are then placed in a frame and exposed to the sun for an hour or two according to its strength. The carbon paper is then laid upon a copper plate in a trough, the paper being first moistened, and is caused to adhere to the copper plate by means of a roller. Boiling water is then poured upon the paper, and after an interval of time which experience alone will indicate, the paper is removed and there remains on the copper plate the mass of carbon from the paper. This is then washed off the plate with hot water, and there remains the engraving in relief upon the copper plate. The copper plate is then dried. The patentee then prepares an alloy composed as follows:—Mercury 10 parts; lead, 8 parts; tin, 12 parts; metal d'Arcet, 70 parts. This alloy, in a state of fusion, is put into a special trough, and upon the alloy is placed the copper plate, with the engraved side upon and next to the alloy. The whole is then put under a press and allowed to get cool. When the alloy is cold, the copper plate is carefully removed, and the alloy bears the fac-simile of the object to be reproduced. After removing the superfluous metal, the plate may be used as a stereotype plate, from which prints may be taken as in ordinary letterpress printing, or as in copper or steel plate printing, or as in printing from a lithographic stone.

The total commerce of the Pacific coast of the United States with Europe, Asia, Australasia, and Oceania during the fiscal year 1884 was 83,565,814 dols.

## UPSETTING STEEL AND IRON.[*]

I HAVE recently read some things in relation to the upsetting of iron and steel which are so much at variance with the generally-accepted ideas on the subject, and at the same time so flatly contradict what the everyday experience of many mechanics shows to be facts, as to prompt me to offer some testimony. First, as to the "upsetting of iron"—for under this heading may be found in a trade journal of recent date a very interesting reference to the "quality of movements of the particles of iron under pressure or percussion. * * * Red-hot iron can be pressed to fill a mould as clearly and exactly as so much wax could be. * * * Cold iron can also be moulded into form by pressure. * * * The heading of rivets, bolts, and wood-screw blanks shows some surprising results in the compression of iron; a No. 6 1in. screw requires a piece of wire slightly more than 1½in. long to form it. Yet the total length of the screw blank headed is just 1in. * * * Now, it has been proved by experiments with shorter bits of wire that less than 5-16ths. of an inch of the extra 8-16ths is required to form the screw-head. What becomes of the remaining more than 3-16ths of an inch in length of an original 1½in. that make the 1in. screw blank? There can be but one answer; the iron is driven upon itself * * * so that $1\frac{1}{16}$in. of wire are compressed into 7-8ths of an inch in length without increasing the diameter of the wire."

This flatly contradicts the assertions of scientific investigators, who have, after making many exhaustive experiments, concluded that cold working of iron and steel, such as hammering, rolling, drawing, pressing, upsetting, &c., do not increase the specific gravity. Is it likely that in the many careful experiments made by the most painstaking of men, the experiments involving the most accurate measurements possible, added to unquestionable tests of specific gravity, there has been uniformly a misconception of the real facts, and that experiments made by measuring a blank piece of wire—possibly with a box-wood rule—before heading, and again measuring the length of blank produced by heading the same wire, are to upset this proven fact, that ordinary cold working does not make iron and steel more dense?

Where does the iron go, then? It goes to round up the contour of the die, in which the blank is headed, that entire part of the block constituting the body, and to fill the die for the entire length of the body of the blank, through the upsetting process, to a fulness which in solid dies defies the efforts of any but the best of carefully-hardened and tempered steel punches, from best of steel, to push out of the dies after heading, rivets, and screw blanks, making the question of what steel to use for "punching out in solid die heading" one of the most important connected with the business.

In heading a screw-blank or rivet, the first effect produced by the longitudinal pressure applied is to upset the piece of wire for its entire length. The diminution in length will produce an exactly proportionate increase in diameter up to the point when the wire fills the die so tightly as to transfer the most of the upsetting effect of the continued pressure to that part of the wire not encircled by the die, and then comes the heading, which begins by increasing diameter, and proportionately decreasing length, the metal being in a measure held by contact with the die and heading punch from lateral expansion. As the pressure continues, it assumes first a pear shape, simply following the not necessarily written law under which all metals under pressure yield in the direction of the least resistance, and soon a shoulder is formed, which, coming in contact with the face of the die, or bottom of countersink, depending upon the shape of die, the direct or entire resistance to the pressure applied has no longer to be supplied by the body of the wire as at first. But still, as the pear-shaped bulb is gradually pressed out of that shape into the shape required in the completed blank or rivet, a time will come when a portion of the superfluous metal back of the body of the blank, or representing the centre of the head, can escape more easily in the direction of the pressure, thereby still further increasing the diameter of the body of the blank, than to escape altogether in a lateral direction under the immense pressure required toward the completion of the heading process.

"Without increasing the diameter of the wire," we quoted, it would not be possible, in any commercial sense, to do anything of the kind. Did the writer who stated as a fact that this was the rule realise the improbability of the statement which he virtually makes—*i.e.*, that over 17½ per cent. of the wire entering into the body of the blank described by him has been lost, if, as he says, the diameter remains unchanged?

I once made some carefully-conducted experiments to prove or disprove the truth of the assertion, which I had often made, that cold swaging did increase the specific gravity of steel, but which was denied by those who, having learned by actual experiment that other cold working did not, felt sure that the effect of cold swaging would be the same as that of other methods. My experiments were made with pieces of steel rod, each 2ft. in length, by reducing them by cold swaging until they were nearly 8ft. long, and, having first carefully measured the original length and diameter, the increased length and decreased diameter, was to show by measurement whether the specific gravity had been increased by swaging. I have not the figures at hand, but they showed on my side; still, when I presented them to my opponents, they met me with the statements that "there was too little difference to talk about, and, if my measurements had been absolutely correct, I had established nothing further than to appear to show the exception, which proved the rule. Cold working did not increase density; this was a well-known principle." Well, it was not much. The fraction of an inch which showed the difference in length of pieces from what they should have been had the specific gravity remained unchanged was represented by a figure in the third or fourth place in decimals—not much like the 0·1875 = 3-16in., which the writer from whom we have quoted would have us believe was lost from 1½in. in length, when it is considered that in my experiments there were pieces sixty-four times as long in which lost metal might hide, and still not more than the one hundredth part as much had hidden in the 8ft. as is claimed for 1½in. Some facts are hard to swallow unless dressed up to appear reasonable. "Upsetting iron," as applied to heading, can be easily upset by anybody who will take the time to compare diameters and specific gravity of wire before heading with those of headed blanks.

"Upsetting steel" is spoken of by some persons, whose information on the subject of steel working is very extensive, as one of the most pernicious of practices, and, by the way the subject is treated, one might suppose that they fully believed that steel was made up of fibres, which must be always worked in the one direction. Steel is of a crystalline nature—not fibrous—and such of it as will be ruined by upsetting within reasonable limits, the operation being performed intelligently, is not good, sound steel.

Pursuing the subject of heading, I can testify that in the days when our grandfathers worked steel I made heading dies of 2in. diameter by upsetting 1¼in. octagon steel, which stood to do as much work as any that I could make from steel of other shape and size. Of hundreds which were made in this way, I do not remember that seams or cracks resulted from upsetting in a single instance. If the steel was sound, and the work in upsetting was so distributed as to affect all parts of the mass alike, why should they?

As to upsetting cold chisels, strips of sheet steel, iron, or pieces of steel of any shape which are so slender as to double up like straws from the power of the blow, there are not enough blacksmiths wasting time and injuring steel in that way to call for any protest. Steel is hammered with a view to improve it many times, in these later days, in a manner so much like that in vogue with the "old chaps" that it is a wonder that so many of them have ceased from labour without ever having been told that they had "monkeyed" steel. Well, if the devil has only got those smiths who hammered cold steel, there are not many smiths in his ranks yet. Heating steel as hot as it will bear and working it while hot, with injunctions not to try to draw cold steel, never to upset, may be construed to mean: hot as is best for steel, no hotter; not cold, but continue hammering till the grain of the steel is well closed up and finer for hammering at a low heat than it could possibly be made if the hammering was all done while the steel was hotter. It dont't seem that everybody does write in the papers against heating steel too hot, and nobody can come to the conclusion that half the trouble is caused by too little heat, if his experience and opportunities for observation have been the same as mine.

What a difference it makes where a chap, old or young, stands to look at a thing. But I am off the track; upsetting steel is the question. The screw-blanks which were headed in the upset dies were threaded with rotary cutters. These cutters may be described as a section of a worm gear, the shape of tooth being that of the space between threads on a wood screw, and the cutter having a rotary motion in keeping with the rotary motion of the screw and with its own longitudinal motion, as it traversed the length of the screw which it cut. The best of steel, according to our best judgment, was used for these cutters; but running through many of the best brands, from "Jessup's" to "Hobson's Choice Extra Best," these cutters did not stand as it seemed they ought to do. I was anxious to try a high grade of a certain brand, of which I could get none of the right size till it could be imported (this was in the days of the old chaps—grandfathers). I had some ½in. or ⅝in. round; the cutters were to finish round, over ¾in. diameter; I could not wait, so I made some cutters by upsetting the steel which I had. These cutters stood to do five times the work of the cutters I had been using; and, willing to "let well enough alone," I continued using the same size of steel and upsetting.

I once had for my job the lathe work on the hook for the Wheeler and Wilson sewing machine. As it came to me it was nothing more or less than a round-headed steel bolt, made in just the same way that a blacksmith would make any solid head-bolt, by drawing a body to pass through the heading tool and upsetting the head. After this lapse of time—thirty years—I can hardly be expected to remember the character of each particular hook, but I don't remember that one of them was unsound as a result of upsetting. If steel gets too much work in one part, and not enough in another, in any direction, hot or cold, it is likely to get broken up. Upsetting need not take all the blame. How much difference in fracture does anyone suppose will be found between breaking a bar of steel crosswise and breaking a piece of the same length of the width of the bar the other way of the grain? Cut two pieces of steel, each 2in. long, from a 2in. square bar, and draw one of them down to 1in. square, or 8in. long in the direction of the length; draw the other piece to the same size and length by upsetting at every other blow, or drawing crosswise. Who believes that the tool made from this last piece will be inferior to the one made the right way of the grain? Some bars of steel, and steel for some uses, can be improved by the work which they can get on the smith's anvil. Some bars of steel, and steel for some uses, will be injured by the same treatment. When it is necessary or desirable to use the centre of a bar of steel, and it is found to be in a coarse condition by reason of having been brought to shape and size by blows disproportioned to its cross-section, there is, perhaps, no better way of improving the grain at and near the centre of the bar than to upset, and alternate the upsetting with work from the outside of the bar.

Upsetting is not a cheap, easy, or desirable thing to do, and is not likely to be resorted to often except when necessity compels, but I see no use in making a bugbear of it when, if properly done, there is no harm in it, and in some cases actual good is done by it. It does not at least break up the centre of the bar, as blows at right angles with its axis often do; and after seeing, as I have, thousands of good cutters made by upsetting, for uses requiring the utmost soundness and best condition of steel, I don't like to see the process tabooed without saying a word in its favour.

## EXPLOSIONS IN PARAFFIN-OIL LAMPS.

AT the Royal Institution on Friday evening last, under the presidency of Sir F. Bramwell, a lecture was given to a very large assemblage by Sir F. Abel, C.B., F.R.S., on "Accidental Explosions Produced by Non-explosive Liquids." Sir F. Abel, referring to a discourse delivered ten years ago on the subject of accidental explosions, stated that his attention had of late been specially directed to one class of such accidents, those connected with the transport, storage, and use of volatile inflammable liquids employed as solvents and as illuminating agents. Particulars having been given of a large number of explosions resulting from the application of flame to vessels which had contained volatile coal-tar or petroleum products or spirituous liquids, the lecturer referred to cases in which the vapour of volatile hydrocarbons had travelled considerable distances from the vessels containing the liquids, and becoming ignited had conveyed flame to such liquids. Instances were also adduced of explosions resulting from the accidental escape of benzoline and similar products into sewers and wells. The violently explosive nature of a mixture of hydrocarbon vapour and air was illustrated by reference to several cases wherein ships conveying petroleum spirit or benzoline had been destroyed, with loss of life, by the ignition of such a mixture which had accumulated in the hold of the vessel, and he pointed out that a fire in a cargo of petroleum oil might be extinguished by battening down the hatches, and so excluding the air. The danger resulting from the carriage of volatile inflammable liquids with gunpowder and other explosive substances having been alluded to, the subject of explosions traced to the existence on board ships of even a small quantity of some preparation containing petroleum spirit or benzoline was dealt with in detail, and it was shown that the explosion which primarily caused the loss of the *Doterel* was due to the escape and volatilisation of a paint "driers" issued to all Her Majesty's ships under the name of "Siccative." The burning of the *Goliath* Poor Law training ship off Grays, Essex, in 1875 was next referred to as an illustration of the conditions under which mineral oils, not easily volatilised, might become dangerous. The development of the employment of liquid hydrocarbons as illuminating agents then received attention, the growth of the shale oil industry, founded in 1850; of the petroleum trade of the United States, dating from the sinking of the Drake Well in 1859; and of the comparatively recent petroleum trade of Southern Russia being traced. The concurrent evolution of the many excellent mineral oil lamps of the present day from the primitive appliances available in the early days of the trade was illustrated by the representative collection of lamps. The lecturer proceeded to discuss the question of accidents occuring in the use of mineral oil lamps, and gave particulars of many such accidents. A careful investigation of the circumstances attending numerous accidents, together with a critical examination of the construction of various lamps, and the results of many experiments, had, up to present time, led the lecturer and Mr. Redwood to arrive at several definite conclusions with respect to the immediate causes of lamp accidents, and to certain circumstances which tended to favour the production of such explosions. If a partially filled lamp were carried or rapidly moved, a mixture of oil vapour and air might be caused to escape from the lamp in close vicinity to the flame, and by becoming ignited might determine the explosion of the mixture existing in the reservoir. A sudden cooling of the lamp by its exposure to a draught or by its being blown upon, as, for instance, in adopting the common practice of blowing down the chimney to extinguish the flame, might give rise to an inrush of air, and the flame might be at the same time drawn or forced into the reservoir. If the quantity of oil in the reservoir were but small, and the air-space large, an explosion would obviously exert greater violence than if these conditions were reversed. If the wick were lowered very much, or if for some other reason the flame were burning very low, the lamp would be liable to become much heated, and the tendency to the production of an explosion would be increased. The character of the wick very materially affected not only the burning quality of lamp, but also its safety. A loosely-plaited wick of long staple cotton would draw up the oil to the flame regularly and freely, while, if the wick were very tightly plaited and made of short staple cotton, it would be of inferior capillary power, the oil would be less copiously drawn up, and undue charring of the wick—with considerable heating of the lamp—might ensue. If the wick were damp when taken into use, or if the oil contained moisture, the capillary action of the wick would be impaired. Many lamps of the newest fashion, too, were so designed as to facilitate the production of explosion, openings or channels being provided through which the flame might pass into the oil reservoir. The adoption of simple suggestions would materially reduce, if not remove, the risk of accident which attends the use of petroleum and paraffin oil, and these were stated at length. It was, he said, desirable that the reservoir of the lamp should be of metal. It should have no opening or feeding-place in the reservoir, nor should there be any opening or channel communication to the reservoir at or near the burner. The wick used should be of soft texture and loosely plaited, it should fill the entire space of the wick holder, but should not be so broad as to be compressed within the latter, and it should always be thoroughly dried before the fire when required for use. The fresh wick should be but little longer than is required to reach to the bottom of the reservoir, and should never be immersed to a less depth than about one-third the total depth of the reservoir. The reservoir of the lamp should always be almost filled before use. If it was desired to lower the flame of the lamp for a time, this should be carefully done, so as not to lower it beneath the metal work more than was absolutely necessary. When the lamp was to be extinguished, and was not provided with an extinguishing apparatus, the flame should not be lowered until there was only a flicker; the mouth should then be brought to a level with the top of the chimney, and a short puff of breath should be projected across the opening. The lamp should remain on a firm support when it is being extinguished. In conclusion, the lecturer expressed the hope that pending the more thorough treatment of the subject by himself and Mr. Redwood, when the investigations referred to were completed, the points dealt with in his discourse which related to accidents with petroleum lamps might, on the one hand, tend to dispel groundless alarm as to the dangerous nature of petroleum and paraffin oil as illuminants, and might, on the other hand, serve to convey some useful information respecting the causes which lead to accidents with lamps, and the readiness with which they might be avoided. Sir F. Abel illustrated the lecture by causing several explosions with gas arising from liquids not in themselves explosive.

## NEW HARTFORD DRILL CHUCK.*

THESE chucks are adapted for holding drills, taps, reamers, wood-boring tools, long stock for cutting or working up, and a variety of other purposes. Fig. 1 is a perspective view, Fig. 2 a longitudinal section, Fig. 3 a transverse section, and Fig. 4 represents in perspective one of the jaws. A is the body of the chuck, and B B′ the jaws. The general construction will be readily understood from an inspection of the engravings. The interlocking teeth, with the V-shaped notches, permit the grasping of any drill, tool, or wire, however small, and at the same time centre it accurately and hold it firmly, without inclination to spring or bend, or otherwise injure it. The square form makes it convenient to apply a wrench to remove it from the lathe or other machine upon which it may be used, and also affords a longer bearing for the actuating screw. The manner in which the jaws are guided, and the actuating screw arranged, tends to preserve truthfulness of the jaws. A. F. Cushman, Hartford, Conn., is the manufacturer.

## A NEW STORAGE BATTERY.

AMONG the most recent types, is a small zinc storage battery devised by M. Reynier, intended to replace the primary cells hitherto used for telegraphy, telephony, railway signals, call bells, etc. It bears an exterior resemblance to the ordinary Leclanché cell; and this resemblance extends to the cylindrical amalgamated zinc and porous cell, but ends there. The positive electrode, placed in the porous pot, is a sheet of peroxydised lead, folded in three directions longitudinally, pierced by numerous transverse slits, and rolled into a spiral; it is reinforced at its upper part by a diametrically placed cap or clamp of copper, surmounted by a screw-post for the connecting wire. The useful surface of the electrode is about 62 square inches; the holes with which it is pierced putting the interior portions in communication with the exterior. The liquid is a solution of bisulphite of potash. This salt in crystals is placed in the central space left by the lead electrode.

To put the battery in operation, it is only necessary to pour water into both compartments. The acid salt dissolves gradually in the porous cell; it diffuses slowly and without great excess in the exterior compartment, where it dissolves the zinc when the circuit is closed. This couple operates like Reynier's ordinary zinc storage batteries, with this difference, that in this case the sulphuric acid is borrowed from the bisulphate of potash. The salt yields an equivalent of acid, the chemical reactions involve then, two equivalents of bisulphate. The substitution of the bisulphate of potash for the free sulphuric acid, and the use of a porous pot, have for their objects the almost entire suppression of local action on the zinc. This small zinc "accumulator" has an E.M.F. of 2·2 volts in use, with one ampère, and a resistance of 0·4 ohm. Its electromotive force, its delivery, and its total work are greater than the Leclanché cell, while its resistance is much smaller—a useful quality in all of its applications, but especially valuable in all of its applications, but especially valuable when used on the carbon transmitters of telephone systems, for it renders the variations in the resistance of the transmitter more sensible, and in consequence augments the strength and clearness of the sounds transmitted. In practice, one of these accumulators will fully replace two Leclanché cells of the same size; the retail price of both being about the same per cell, the substitution of the new system for the old will result in a saving of 50 per cent. on the cost of installation. The regeneration of the accumulators may be effected in two ways:—First, by replacing the electrodes and exhausted liquid; second, by passing through the cell, during 40 to 50 hours, a current of about ·5 ampère, furnished by a dynamo machine. The expense of this work is, at the most, about $\frac{1}{10}$th of 1 h.p. This method being much more economical than the first, would be exclusively employed where the accumulator was used on a large scale for telegraphy and telephony. The small zinc accumulator possesses a great elasticity of performance; it may either expend its charge in a few hours, or extend its work over a period of six months. Under ordinary circumstances, the regeneration should be practised at intervals of three months. As the electrodes will bear 100 chargings, the life of the accumulator will exceed 25 years.

## PLATINISING GLASS.

THE following method of depositing brilliant films of platinum on glass was described recently at a meeting of the London and Provincial Photographic Association, when samples were shown. The method is that devised by Prof. Böttger. In order to succeed in coating porcelain or glass with a perfectly faultless film of platinum, of the brilliancy of silver, it is indispensably requisite to make use of a perfectly dry chloride of platinum, which must be as free from acid as possible. To that end pour some oil of rosemary over the perfectly dry chloride of platinum in a small porcelain mortar, and knead it up with the pestle, renewing the oil about three times, and continue this operation until at length there is produced from the brownish-red chloride a soft plaster-like mass, the colour of which is as black as pitch, and wherein no particles of undecomposed chloride of platinum are discoverable. The oil of rosemary assumes hereby a more or less yellow colour, in consequence of its partially taking up chlorine from the chloride of platinum. When at length we have arrived at converting the whole of the chloride of platinum into the black plaster-looking mass spoken of, rub it well up with the pestle, after pouring the oil of rosemary off, with about five times its weight of oil of lavender, and continue to do so until it has become a perfectly homogeneous thin fluid. It must then be left to stand for half an hour or so, for it is not until after that interval that it can be used with advantage for platinising. For the production of the brilliant platinum film, all that is now required is to apply the mass as uniformly as may be, and in the thinnest possible coat, to the objects of porcelain, earthenware, or glass by means of a soft, delicate brush. The thinner the coat of the above described preparation, the more brilliant the film of platinum subsequently proves. When, in fine, the articles have been gone over as thinly as possible with the fluid conformably with these instructions, all that is required further is to subject them for a few minutes to a very low, scarcely-perceptible red heat, either in a muffle, or in the flame of a Bunsen's gas blow-pipe used with caution. The articles receive from this baking (supposing always that the temperature described has not been exceeded), without requiring any subsequent treatment, an incomparable beautiful lustre, as brilliant as silver. If, by any oversight, the coating of platinum upon the articles has turned out faulty, or in the case of breakages occurring during the baking, every trace of the metal may be recovered with facility, from the objects that have suffered, by means of the following very simple galvanic process, without being obliged to have recourse to the use of aqua regia. Nothing more is required than to pour common hydrochloric acid over them, and then touch them with a zinc rod. On doing this, as quick as lightning, in consequence of the hydrogen evolved both at the upper and lower surfaces of the film of platinum, which acts as the negative pole, we see the shining metallic coating peel off in the form of infinitely thin leaves from the base of porcelain or glass, and, notwithstanding the specific gravity of the metal, ascend partially and float on the surface of the acid. On separating the hydrochloric acid by the use of a filter, the whole of the platinum, which would be otherwise lost, is recovered, so that no complaint arises as to the waste of any of the metal in question. In conclusion, I have to observe that one should prepare at once only as much of the platinising fluid as is required for the day's use, inasmuch as it loses in efficiency by keeping. That which, according to my observations, forms the active principle in the fluid, which results from treating chloride of platinum with oil of lavender, as above described, is an organic platinum salt, which, in point of fact, one can obtain, after some time, in the form of small elongated octohedral crystals, of a pale yellowish colour, by washing out carefully with alcohol a tolerable quantity of the fluid. The crystals have the property of taking fire with a brilliant flame on being brought near a lighted candle, leaving a residue of compact platinum of a dazzling whiteness.

## WATER MOTORS.

THE following is the substance of a lecture delivered by Prof. W. C. Unwin, M.Inst.C.E., before the Institution of Civil Engineers. It formed one of a course of lectures on the "Theory and Practice of Hydro-Mechanics."

The lecturer remarked that water-motors were not in this country so important as heat-motors, but yet a larger amount of water-power was utilised than was commonly supposed. Either a rise in the price of coal or greater ease in the electrical transmission of mechanical energy would make water-motors more important. At Windisch 1,000 h.p. were utilised, and at Bellegarde 3,700 h.p. But it was in America that the largest installations were found. For instance, at Holyoke, a weir 30ft. high and 1,000ft. long had been built across the river, and the water, taken off above the dam in a canal 140ft. wide and 22ft. deep, supplied power to the mills. Two other canals on lower levels had also been constructed. The whole water-power available was 20,000 h.p. in ordinary dry seasons, and the power was leased to the mill-owners at the rate of £1 per effective h.p. per annum. When water was descending from a higher to a lower level, in a pipe, for instance, it would in general have acquired, at any point, velocity and pressure. Then if H was the total fall,

$$H = h + \frac{p}{G} + \frac{V^2}{2g}$$

where the terms on the right represent three forms the energy took—viz., unexpended fall, pressure head, and velocity head. Corresponding to these were three classes of water-motors.

1. Cell or bucket wheels utilised the energy of an unexpended part of the fall. They were simple, had a fairly high efficiency, but were applicable only in a limited range of fall, and were cumbrous. They had one good point—that the efficiency varied little with a varying water-supply.

2. There were water-pressure engines, which utilised water pressure, just as a steam-engine utilised steam pressure. Water-pressure engines were used in mining districts, and hydraulic cranes and hoists were machines of the same kind. Still it was not generally best to utilise water-power in this way. The reasons that a cylinder and piston acted so well with steam, and less well with water, were these:—(1) The frictional losses in fluids were proportional to their weight for equal velocities of flow. If water were 500 times heavier than steam, then the friction at given velocities would be 500 times greater. Hence the piston-speeds, which might be 400ft. or 500ft. per minute in a steam-engine, were rarely greater than 60ft. in a water-pressure engine. In the pipes the steam might flow at 100ft. per second, but water only at 6ft. to 10ft. Hence the water-pressure engine was much more cumbrous than a steam-engine. (2) From the incompressibility of water, the same volume was used in a pressure-engine, whatever the amount of work to be done. The system of hydraulic-pressure-mains introduced by Sir W. Armstrong had proved entirely successful for intermittent work, such as lifting, but not so successful for ordinary power purposes. Probably the reason was that the consumption of water in pressure-engines was extravagant. The only engine in which the consumption of water varied with the work to be done was in that invented by Mr. Hastie, and which, in an improved form, was being introduced in London by Mr. Ellington. In this, by automatic gear, the stroke of the engine was lengthened till the resistance was just overcome. (3) There were other difficulties which arose out of the weight and incompressibility of the water. The whole column of water between the engine and the supply-reservoir virtually formed part of the piston, so that a pressure-engine had a very heavy piston, and this in general tended to render the effective effort variable. In certain cases the action of the friction and inertia of the water were favourable to particular operations. Mr. Tweddell's hydraulic riveter furnished an example of a machine in which the inertia of the parts was virtually that of 300 tons acting at the riveter-ram. To control such a mass, powerful brake action was necessary, and this was supplied by the automatic action of the friction of the water in the supply-pipe. The friction, while preventing the velocity becoming excessive in the early part of the stroke, when there was little resistance, diminished when the velocity was checked in closing the rivet, and allowed the development of a high effective pressure at the end of the stroke.

3. There were motors in which the head was allowed to take the form of energy of motion, and in which the water acted in virtue of its inertia. It was first necessary to consider in what ways this energy might be wasted. There was a waste of energy if the water broke up into eddies or irregular motions. Energy might be rejected from the machine into the tail-race; and lastly, energy was lost in friction against the surfaces of the machine. In a good motor the loss due to breaking-up could be almost completely avoided, if the passages changed gradually in section, if the surfaces had continuous curvature, and if the inclination of the receiving edges of the vanes was in the direction of relative motion. The loss due to rejection of energy could also be made very small, but by reducing this beyond a certain point, the loss from skin friction was increased.

The nature of a turbine would be best understood by considering first some simpler machines. In an ordinary undershot wheel, about 25 per cent. of energy was rejected into the tail-race, and about 25 per cent. was lost in shock, besides the losses due to shaft-friction and leakage. Suppose that instead of striking normally a flat float the water struck a hollow cup. Then both the losses in shock and in energy rejected were greatly reduced. An interesting motor of this kind has been introduced in California. Water power was there obtained from canals or ditches built to supply the mines, at elevations of from 1,000ft. to 3,000ft. above the valley. The fall was too great for an ordinary turbine, and a kind of undershot wheel with cup-shaped floats was used. Thus, at the Idaho mines, seven of these wheels were used, working to 320 h.p. The water was brought in a 22in. wrought-iron main, the head being 542ft. The water was delivered on to the wheels from nozzles $\frac{15}{16}$in. to $1\frac{15}{16}$in. in diameter. These wheels were said to give 80 per cent. efficiency, and in the special circumstances, where the jets were of small diameter under very high pressure, a high efficiency was probably obtainable. Such a wheel was the simplest form of an impulse turbine.

Next, consider a machine well-known at one time as the Scotch turbine. The water, entering the centre of the wheel, was discharged from tangential jets, and drove the wheel by reaction. The water issuing from the jets had a backward velocity, and energy was therefore rejected. It was the study of a wheel of this kind which led Fourneyron to the invention of the turbine. Fourneyron saw that the only way of reducing the backward velocity of discharge, and to prevent the waste of energy, was to give the water an initial forward velocity. The Fourneyron turbine was a reaction wheel in which initial forward velocity was given by fixed curved guide-blades. In the Fourneyron turbine, the water descending into the centre of the wheel issued radially outwards. Its greatest defect was the form of the regulating sluice, which diminished seriously the efficiency for diminished water-supply. It was followed by the Jonval turbine, in which the water flowed parallel to the axis, and by the inward flow turbine first perfected by Professor James Thomson. In the ample space outside an inward flow turbine, better regulating apparatus could be arranged than with any other form.

In all turbines as first constructed, the water issued from the guide-blades with a velocity less than that due to the head, and, therefore, there was a pressure in the clearance-space between the guide-blades and the wheel, and such turbines were called pressure turbines. Mr. Girard was the first to perceive the advantage of departing from Fourneyron's practice, and to allow the water to enter the wheel with the whole energy of motion due to the head. Such turbines were called impulse turbines. In pressure turbines the water must enter the whole circumference of the wheel simultaneously, and fill the wheel passages, or the pressure in the clearance space could not be maintained. Further, there must be a definite rate of flow through the wheel to maintain the distribution of pressure and velocity for which the turbine was designed. In impulse turbines each particle of water acted for and by itself; the wheel-passages were not filled, and the water might be shut off from any part of the wheel-circumference without affecting the action of the water. Regulation was, therefore, easier in impulse than in pressure turbines.

The consideration of the action of water in a turbine was facilitated by replacing the turbine-wheel by a turbine-rod, that was by supposing the turbine to have straight instead of circular motion. From such a rod, the transition to the case of a turbine-wheel by simple projection was easy. The water, entering vertically, was deflected by fixed guide-blades, till it had a horizontal velocity, $w_i$; it then entered the wheel, the vanes of which were so placed as to receive it without shock, and was deviated back to a vertical direction, having given up all its horizontal energy of motion. Hence, applying Newton's second law, $\frac{w_i}{g}$ was the horizontal pressure driving the wheel, due to each pound per second of water. But V being the velocity of the wheel, the work done on the wheel, $\frac{w_i V}{g}$ feet-pounds per second. Now the work might also be written $\eta$ H, where H was the effective fall, and $\eta$ the efficiency. Hence

$$\frac{w_i V}{g} = \eta H.$$

was the fundamental equation in designing a turbine.

There was one point in the action of a turbine which was unfavourable. The efficiency varied with the speed. There was a speed of maximum efficiency. But with pressure-turbines the speed of maximum efficiency diminished with the closing of the sluice. Now, in general, a turbine must be run at one speed. If it was run at the speed of greatest efficiency for a full sluice, then for a partially-closed sluice the efficiency was reduced both by the action of the sluice, and by the fact that the speed was not the best for that position of the sluice. In the mode of regulating turbines, great differences of efficiency arose. The worst mode of regulation was by a throttle-valve, which acted by destroying part of the head. Next to this, perhaps, the worst was the circular sluice, used with the Fourneyron turbine. Some modern turbines gave, in experiments which appeared to be reliable, much better results. The best mode of regulation for a pressure turbine was by means of movable guide-blades, invented by Professor James Thomson. In a Girard turbine the regulation was not so difficult, and results of an experiment carried out under the direction of Professor Zeuner, on a 200 h.p. Girard turbine, gave 79·5 per cent. efficiency with full sluice, and 80·1 per cent. with half-sluice.

## SCIENTIFIC SOCIETIES.

### ROYAL ASTRONOMICAL SOCIETY.

THE Society held a meeting on Friday, the 13th inst., at their rooms at Burlington House, Ed. Dunkin, Esq., F.R.S., President, in the chair.

Mr. Lecky stated that a few months ago a remark had been made at the Society to the effect that the manufacture of crown glass for optical purposes had practically ceased. He was glad to be able to state that Mons. Charles Feil, the son of the celebrated Paris maker of crown glass, had started business again, and we are now likely to have as large and as perfect discs of crown glass as formerly.

Mr. Downing read a paper on "Star Places in the *Nautical Almanac*." He said that in the *Nautical Almanac* for 1884 a change was made in the mean Right Ascension of 182 stars, whose places were derived from the Greenwich Nine-Year Catalogue. In looking over the Right Ascensions for these clock stars, he came to the conclusion that the average discordance was under five-hundredths of a second, there were 24 stars with a discrepancy of more than five-hundredths, and the average of their discordance only amounted to ·064 of a second. These discordances appeared to arise from inaccuracies in the proper motions which had been adopted. In the 1883 *Nautical Almanac* there would be 22 years' proper motion to be applied. The proper motions he had adopted had been taken from the values computed by Prof. Main and Mr. Stone, and by comparing Airy's earlier Greenwich observations with Bessel's reductions of Bradley's places. By applying these new proper motions the average discordance had been reduced from ·064 to ·042 of a second. This demonstrated the superiority of Prof. Auwers' proper motions, and showed the desirability of their adoption in this country.

Mr. Knobel read a paper by Prof. Oppolzer on "The Proposed Change in the Astronomical Day," advocating the adoption of universal time reckoning from midnight, and pointing out that little difficulty would be experienced in changing the heads of the columns of the *Nautical Almanac*.

The Astronomer Royal said that he had received a letter from Prof. Oppolzer stating that he was going to give practical effect to his views by adopting the new reckoning of time in a list he was now preparing of 8,000 solar and 5,200 lunar eclipses between B.C. 1207 and A.D. 2061. He felt very glad that Prof. Oppolzer had expressed his opinion so strongly, because at the Washington Conference there was no scientific Austrian delegate present, and the Austrian diplomatic delegate had abstained from voting. M. Struve, the director of the Pulkova Observatory, had recently written to him, stating that he was about to adopt the new time for internal use in the Pulkova Observatory, and suggesting that the change should not be made till 1890, by which time it could be adopted for the predictions of the *Nautical Almanac*, and other other national ephemerides, which are all published three or four years in advance.

Capt. Wharton said: I wish to remind the society that the Governments of the world print these almanacs chiefly for the use of sailors, and that their use by astronomers ought only to be a secondary consideration. If any change is to be made in the time to be used in the *Nautical Almanac*, it ought not to be made without very ample notice. A very large proportion of the ships of Great Britain are navigated by men who make their calculations entirely by rule of thumb, and who would be very easily confused by a change of twelve hours. I am, myself, in favour of the change; but think that it should not be made until some years have elapsed, and ample notice has been given to the educated sailor of what is about to be done.

General Strachey said: My having been present as one of the delegates of Great Britain at the Washington Conference entitles me to say a word on the subject. I think that we are bound, now that other nationalities have accepted our meridian, not to take any further steps without consulting the civilised world. It so happened that at the time the conference was sitting the change in the presidency of the United States took place, and the American Government has not yet taken any action on the report of the conference. No doubt before long some action will be taken either by the American Government, or some other of the governments which were represented. It will then rest with our Government to move, but it would not be decent for us, having pledged ourselves to consult with the rest of the civilised world, to take independent action; but no doubt that reserve on our part need not last beyond a reasonable time.

Mr. Spitta described an observation of a transit of Jupiter's fourth satellite. As it approached the centre of the disc it became black in colour, and assumed an oval shape, the longer axis of which was parallel to the belts.

Mr. Knobel said that he had observed the transit, and noticed that when it was first seen upon the disc it appeared as a bright spot. After five minutes it became slightly darker upon the disc, and after a quarter of an hour it seemed to be quite black; but it had appeared to him as a perfectly round black spot.

Mr. Ranyard asked whether Mr. Spitta had examined his observing eyepiece for the purpose of testing whether it was astigmatic with a vertical axis.

Mr. Spitta said he had carefully examined his own eyes, and he was not astigmatic. He had referred to several accounts of observations of transits of satellites, and had found that several observers had stated that the disc of the satellite when seen up on the body of the planet appeared not to be round. In some instances they described it as irregular, and even triangular in shape.

Mr. Common said that such appearances might possibly depend upon the instrument as well as upon the observer's eye. If the instrument made use of was a reflector, a little want of adjustment might make it appear elliptical.

The Earl of Crawford said: I was in hopes I should have had a comunication from Dr. Copeland, which I could have read at this meeting, describing an observation of a transit of one of the satellites made so near to the time of opposition that Dr. Copeland was able to observe the satellite occult its own shadow on the body of the planet. It was a very curious observation, as it showed that the sun, the earth, the satellite, and the part of Jupiter's disc occulted, must have been all in one straight line at the time, and as seen from the disc of Jupiter, the earth must have appeared to be transiting the disc of the sun.

Mr. Knobel read a note from Capt. W. Noble on the *Nautical Almanac* dimensions of the Saturnian system. The note was accompanied by some drawings illustrating the fact that the ball of the planet appears larger than it would appear according to the dimensions given in the *Nautical Almanac*.

Mr. Green said that he quite coincided with Capt. Noble as to the discrepancy in the *Nautical Almanac* dimensions. According to the proportions given in the *Nautical Almanac* the ball would not touch Cassini's division in the rings.

Mr. Stone said: I do not see Mr. Hind here, but I think that the matter has already been brought to his notice, and that he intends to make some changes in the measures of Saturn and its ring which have hitherto been adopted in the *Nautical Almanac*.

The Astronomer Royal read a paper on "Spectroscopic Observations of the Motions of Stars in the Line of Sight made at Greenwich during the Year 1884." The observations were made by Mr. Maunder and Mr. Nash with similar spectroscopic means to those which had formerly been employed an unusually large number of stars had been observed, 54 of which have been reobserved five times. The displacements have also been checked by observations of the planets. The displacement in the case of Venus does not agree very well; it is considerably larger. That for Mars is not far out—they are both right in direction. The displacement for the two limbs of Jupiter agrees very well with the computed displacement. It should be remembered, however, that the observations are subject to large discordances; but there are, nevertheless, some results which seem to be satisfactorily proved. Mr. Maunder has made 25 measures of the displacement of lines in the spectrum of Sirius on thirteen nights, and these give a mean motion of approach of 22 miles per second. This corresponds to the direction of motion which has been observed of late years; but it is opposite to the direction of motion which was deduced from the earlier Greenwich results and from the observations of Dr. Huggins. We have now a progressive change of motion from 25 miles per second of recession to 22 miles or so of approach. These observations have been carefully made at different times of the year, because it is possible to suppose that there might be a very rapid orbital motion of the star in a few months round some dark body in its neighbourhood; but in no instance has such very rapid motion been detected.

The Earl of Crawford said: I should like to know, before the meeting breaks up, whether any statement is to be made at the instance of the Council with reference to the request which has been signed by more than a hundred Fellows of the Society, asking that a change may be made in the by-laws, permitting voting by proxy.

The President said: I do not think that I have anything to communicate to this meeting. Lord Crawford will find that a resolution on the subject has been passed by the Council; but I have not been instructed to make any communication to this meeting on the subject.

The Earl of Crawford: Then I suppose the Council will not be surprised if, in the ordinary course of events, they receive a requisition to call a special general meeting to take the matter into consideration. I apprehend that there is a strong feeling amongst the Fellows of the Society who are non-residents in London, that they should have a voice in the management of the Society which at the present moment is denied them.

Mr. Common: May I be allowed to interpose, in the interests of order? In the first place, Lord Crawford is utterly wrong in moving in a question which relates to the alteration of by-laws of the Society at an ordinary meeting. In the second place, I think a great deal of misunderstanding might be removed if the President were to state the conclusion which the Council have arrived at to-day—it must come out sooner or later.

The Earl of Crawford: I am not moving any motion with regard to the alteration of the by-laws. I am simply asking what answer has been made to the Fellows who signed the request?

Mr. Beck: Would you allow me to inquire whether the constitution of the Society permits matters relating to the by-laws to be discussed at the evening meetings. I conceive that it does not, and as this matter relates to the by-law, it ought not to be referred to.

Mr. Stone: As this matter has been before the Council, they ought to be able to communicate the decision which has been come to.

The Astronomer Royal: I must protest against a meeting for scientific purposes being converted into a meeting for the discussion of by-laws. There is a great distinction between the ordinary meetings and special meetings, and I think we shall spoil the character of these meetings if we allow a discussion of this kind to be sprung upon us.

Mr. Beck: I conceive that it would be altogether out of order for the Council to give to this meeting any information with regard to the result they have arrived at. (Cries of "No.") As I understand it, the alteration of the by-laws rests with the meeting of the Fellows of the Society specially convened.

The Earl of Crawford: I am blamed by the Astronomer Royal for rising up in my place to inquire what information is going to be placed before us this evening. No harm can possibly be done by making the statement I have asked for, and if the statement is not made, the Fellows who have signed the request to the Council will lose a month, for they will not be able to prepare a requisition for a special meeting until they know the action that has been taken by the Council. If their notice is put off for a month, the special meeting is put off for two months, and that means to the end of the session, when the matter will be shelved.

Mr. Knobel: I do not know how Lord Crawford gets over the by-law which says that certain matters may be brought before ordinary meetings, "provided always that the same do not relate to the by-laws." The requisition which Lord Crawford refers to distinctly stated that it was a request to alter the by-laws. Therefore the subject he brings forward does relate to the by-laws, and how Lord Crawford can conceive he is in order, I am at a loss to understand.

Lord Crawford: I have not asked any question with regard to the by-laws, or attempted to move any motion with regard to their alteration. I have asked for information with regard to the business of the Society.

The President: I am quite prepared to read the resolution which has been come to, and I think that had better bring the discussion to a close. The Council has spent a considerable time to-day over the question, and they have discussed it with great fairness, and the conclusion they have come to is as follows:

"That the signatories to the request to the Council to take steps for altering the by-laws so as to permit Fellows unable to be present at the annual meeting to vote by proxy, be informed that the Council do not propose to recommend such a change. The Council, however, are of opinion that to enable all Fellows who cannot attend the Annual General Meeting to vote for the election of officers and Council by post under suitable precautions, might fitly form the subject for discussion at a special general meeting of the Fellows."

The Earl of Crawford: Will you kindly inform me how I can put myself in order in moving an amendment to that resolution?

The President: By getting five Fellows to sign a requisition to the Council to call a special meeting for such and such a purpose. That will be laid before the Council at their next meeting, and they will give the usual notice, and it will be considered after the May meeting.

The meeting adjourned at ten o'clock.

## ROYAL MICROSCOPICAL SOCIETY.

THE sixth meeting of the session was held on the 11th inst., at King's College, Strand, W.C., the President, the Rev. Dr. Dallinger, F.R.S., in the chair.

Hardy's Collecting Bottle with Improved Stopper.—Mr. Crisp said that, while it was not usual to look a gift horse in the mouth, it was necessary to warn microscopists against the use of Mr. Curties' so-called improvement, which consisted in substituting for the original indiarubber stopper a rectangular one of glass, which was greased in order to make it water-tight. The nuisance in the field of a collecting bottle with a greased stopper was sufficiently obvious.

Mr. Hardy disclaimed any responsibility for the change that had been made.

Mr. Crisp exhibited (1) Winkel's Class Microscope with movable stage, (2) Tolles' Clinical Microscope, (3) Siebert's Portable Microscope, and (4) Swift's Microscope for Examination of Disease in Skin of Sheep, and having a very long working distance, (5) Griffiths and Bertrand's Objective Adapters, and (6) a new form of "Finder."

Mr. H. G. Madan exhibited some new kinds of glass. He found that a combination of ordinary blue glass with a peculiar bluish-green glass, known as "signal-green" glass, was much more convenient than the usual glass cell filled with solution of cuprammonium sulphate. Glass coloured with cobalt absorbs most of the rays of medium refrangibility, but transmits, besides blue rays, a portion of the red rays in the neighbourhood of Fraünhofer's line A. The "signal-green" glass (so called from its being used for railway signal lamps) is remarkably opaque to red and yellow rays, and hence if a piece of it is superposed on cobalt blue glass, the only light transmitted by both is that which lies between Fraünhofer's lines F and G, constituting a beam at any rate not less homogeneous than that transmitted by cuprammonium sulphate. In cases where the double thickness of glass may be an inconvenience, as in discs for stage diaphragms, a plate of "flashed" blue glass may be cemented, flashed side downwards, upon the signal-green glass, and then the whole of the colourless part of the blue glass can be ground away, leaving only the coloured film upon the signal green, and thus forming a plate hardly thicker than the latter alone.

Mr. Baker exhibited some object boxes in book form for placing on a shelf with books, the objects then lying flat.

Dr. C. V. Zenger's letter was read, describing a new mounting medium, consisting of tribromide of arsenic in bisulphide of carbon, and giving a refractive index of from 1·6696 to 1·7082. An improved slide for viewing the object on both sides was also described.

Mr. C. H. Hughes' description was read of a stage for use with high powers, to prevent the decentring of the condenser, especially when used with immersion contact. Vertical, horizontal, and oblique motions are given to the slide while the stage remains stationary, but can be rotated.

Mr. E. M. Nelson exhibited a drawing of *Bacillus subtilis* made with Dr. Beale's neutral-tint reflector and a 1-12in. oil-immersion objective.

The President remarked upon the unusual appearance of the object, which was represented as a series of beads without any connecting tissue, instead of a tube with possible spores within.

Mr. Nelson explained that being mounted in balsam the tube would most likely become obliterated. His main object was to show the flagellæ.

Mr. J. Mayall, jun., described the original ruling machine of the late Herr F. A. Nobert (now the property of Mr. Crisp), which was exhibited to the meeting. He said he should not enter minutely into the details of the construction, as they could hardly be understood without a close inspection of the machine, many portions of which were too delicate and complex to be handed round to the meeting. The foundation of the machine was a dividing engine calculated to produce parallel divisions far finer than could be marked by any ruling point yet discovered. The division-plate had 20 circles of "dots," and these were supplemented by extremely fine graduations on two bands of silver imbedded near the edge, which were viewed by means of two compound microscopes, each provided with eyepiece screw-micrometers of special construction. The movement of rotation was effected by a fine tangent screw acting upon a worm on the vertical edge of the division-plate. The tangent screw was controlled by a large milled head about 4in. in diameter, and a graduated drum showed the amount of motion. The method employed by Herr Nobert for obtaining the minute divisions of his test-plates (ranging from $\frac{1}{1000}$th to $\frac{1}{20000}$th of a Paris line) was to convert the radius of the division-plate into a lever to move the glass plate on which the rulings were made at right angles to the motion of the ruling point. For this purpose, he attached to the centre of the rotating division-plate a bent arm on which slided a bar of silver, having at one end a finely-polished steel point which could be adjusted by a scale and vernier so as to project more or less beyond the centre of the division-plate or axis of rotation. The radius of the division-plate thus became the long arm of the lever, whilst the radius of the projection of the polished steel point beyond the axis of rotation formed the short arm, the centre of the division-plate being the fulcrum. The motion of the short arm of the lever was communicated by contact with an agate plate to a polished steel cylinder adjusted to slide at right angles to the movement of the ruling point in V-shaped bearings of agate. The steel cylinder carried a circular metal table on which the glass plate to be ruled was fixed by wax and clamps. The motion of the lever arms was, of course, in arc, and hence the divisions would not be strictly equidistant unless compensation were made for the difference in length of the arc and its sine; but since the actual space included between the first and last lines of Herr Nobert's test-plates hardly exceeded 1-50th inch, this difference would be inappreciable. The arrangement for carrying the diamond point was, he believed, wholly designed by Herr Nobert, and was a most ingenious combination of mechanism—not "ingenious" in the sense often alluded to by Mr. Crisp, which generally meant both complicated and useless, but in the sense of combining inventiveness and efficiency. The questions to be solved were (1) To provide means to adjust a diamond edge to any angle (within required limits); (2) to balance it truly so that the weight-pressure for ruling might be perfectly controlled; (3) to raise and lower it strictly in one plane—that is to say, mechanically free from lateral play, so that the consecutive divisions of the ruling depended solely on the motion imparted to the glass plate by the dividing engine; (4) to cause the diamond to oscillate freely in one plane; (5) to control the length of the lines to be ruled; (6) to connect the whole with mechanism to insure an even rate of speed in the ruling movement of the diamond. These matters had been worked out by Herr Nobert with extraordinary perseverance, as evidenced by the elaboration of the adjustments. From the point of view of so accomplished a mechanician as Dr. Hugo Schröder—to whom he (Mr. Mayall) must publicly express his obligations for explanations connected with the machine—the design of this portion of the machine might be much simplified without loss of accuracy or delicacy of action. In particular Dr. Schröder noted that the whole of the movements might be made to act automatically, whereas Herr Nobert went through the process of adjusting the dividing engine and winding up the train of wheels for each line ruled on his test-plates—a labour demanding prodigious patience. It should be observed, however, that Herr Nobert had always to work with very limited means. The success of his efforts must be estimated by those who were familiar with his ruled plates, and who had compared them with others. For the production of diffraction gratings and ordinary micrometers, where the equidistance of the lines was an essential factor, and where the breadth of space covered by the lines was so large that the lever motion in arc of the dividing engine would have introduced errors in the evenness of the division, Herr Nobert removed the bent arm from the centre of the division plate and substituted a vertical cylinder, on which he coiled an extremely thin flat steel spring having a hook at the free end; this hook was attached to a stud beneath a straight cylinder of polished steel, which carried the glass plate to be ruled under the diamond, and which took the place of the more delicate arrangement for the test plates. The rotation of the division-plate caused the vertical cylinder in the centre to rotate, coiling the steel spring, and thus, after the manner of a windlass, hauled along the diffraction-plate carrier at right angles to the ruling motion of the diamond. Presumably Herr Nobert used the stud and "dots" of the division-plate to divide the diffraction plates and micrometers, for the verification of 12,000 consecutive divisions (of which some of his diffraction gratings consisted) by means of the microscope, would have been too much for even his patience. Mr. Mayall then referred briefly to the preparation of the glass plates for the rulings, which he said were of specially "mild" composition. He believed that Herr Nobert's earlier rulings were upon artificially prepared surfaces on the slips themselves, and that later on (about 1860) he came to the conclusion that the melted surface of cover-glass was better for his test-plates. Subsequently Dr. Schröder instructed him in a method of polishing the "mild" glass, which induced him to revert to artificial surfaces again. The later test-plates were probably all ruled on the prepared "mild" glass, thinned down to suit high-power objectives. Mr. Mayall said he must defer his remarks on the diamond points till the next meeting; he mentioned that the ten diamonds that accompanied the machine presented varieties of preparation. Some had two worked surfaces brought to a knife edge; others one worked surface and one surface of fracture meeting in a knife edge; others had two surfaces of fracture meeting in a knife edge. By reference to Herr Nobert's memorandum book, Mr. Mayall said he hoped to be able to explain the character of the diamonds which were noted upon as being successful. In conclusion, Mr. Mayall said it was abundantly proved by Herr Nobert's work that the perfection of the mechanical part of the dividing engine was not the only difficulty which he had understood and conquered. There was a still greater difficulty which he had understood, and which he had met with a success that gave him pre-eminence in this department of micro-physics, and that was the preparation of the diamond ruling points.

The President expressed the thanks of the meeting to Mr. Mayall for his description of a machine which exhibited such an immense amount of commendable ingenuity in its construction. He thought it must be a source of gratification to the society to know that as the machine now belonged to Mr. Crisp, they might hope at some future time to hear more about it, and to see something of its performances.

Mr. Beck said that a paper upon this machine, giving all the details of its construction with illustrations, would be extremely interesting, and he hoped that Mr. Mayall would not only describe its perfections, but would also point out all its weak points, which were sometimes even more interesting and instructive, as showing the manner in which the inventor had been able by practice to overcome them. He remembered that many years ago the micrometer ruling machine by Mr. Jackson produced in his hands some of the best work of its kind that had then been seen; but when after his death it passed into other hands, some of the worst productions resulted. Mr. Jackson had, no doubt, found out all its weak points, and had overcome them by the exercise of his own manipulative skill; and it would be very interesting to know how Nobert had got over all his difficulties, so as to be able to produce bands of lines which stood altogether unrivalled.

Mr. Crisp said that Mr. Mayall had kindly undertaken to describe and illustrate the machine in a future number of the *Journal*.

Mr. Mayall said that on looking over Herr Nobert's memoranda, he found that in ruling his 30-band plate, after satisfying himself that the diamond point was in order, his next care was to ascertain exactly what weight was required to give the necessary pressure, and no more. The memoranda showed that he began the first band of lines with a weight of 30 grammes, and reduced the weight for each successive band until he arrived at about 3 grammes for the highest band.

Dr. Matthews inquired if there was any provision made for dropping the point upon the plate on commencing a line?

Mr. Mayall said this seemed to be one of the weak points of the machine, for it would be seen, on examination of the test plates, that there was frequently a small fracture at the beginning of a line, and that at the end of it there was a slight hook-shaped irregularity. A very delicate arrangement had been devised for causing the point to be lifted automatically; but the shock produced by the sudden arrest of motion was translated on the end of each line by a hook.

Mr. C. Beck exhibited a modification of the "Complete" lamp, fitted with a shallow glass reservoir instead of the original one of metal. It was thought this alteration would tend to prevent condensation or "sweating" of the paraffin upon the surface. He also exhibited a "Vertical Illuminator," with a new form of diaphragm.

Dr. Van Heurck's note was received sending a copy of Prof. Abbe's opinion on the photographs of the "beads" of Amphipleura pellucida, in which he stated that he had no reason to doubt the reality of the beads.

Mr. Crisp said there was one very curious misapprehension in connection with this diatom discussion. Dr. Flögel, it would be remembered, inveighed somewhat strongly against Prof. Abbe's theory, which he considered to be antagonistic to his researches. The fact was, however, that Prof. Abbe had always considered Dr. Flögel's methods of investigation as the only proper and rational ones in regard to diatom striæ, and his own theoretical views strongly confirmed this.

Dr. J. D. Cox's note was read as to actinic and visual foci. Statements have recently been made that with modern undercorrected microscopic objectives there is no difference between these foci, and that no allowance need therefore be made in focussing. Dr. Cox, while finding this correct for the generality of objects, remarks that it does not apply when large amplifications are in question. When powers of 1,500 and 1,600 are used for photo-micrography, there is a distinct difference between the two foci, and it is, therefore, still necessary to give particular attention to the focussing in order to obtain sharp photographs.

Mr. J. Kitton's remarks on Balsam of Tolu were read as follows:—It is stated in the February number of the *Journal* that this medium is objectionable for mounting purposes, as crystals are apt to form in it sooner or later. I tried it shortly after reading Dr. Kain's recommendation (early in September last) and have now over one hundred preparations in this medium. In February I went through them with some trepidation, but was gratified to find that no symptom of crystallisation had appeared. This I should have attributed to the short time that had elapsed since the preparation had been made, had it not been stated that recent preparations (made about the same time as mine) are already full of crystals. I can only account for this by supposing that either Tolu is variable in its composition, or that my method of preparing and using it prevents crystallisation. Dr. Kain recommends alcohol or chloroform as solvents; I employ benzole. I remember some years ago inquiries were made as to the cause of crystals sometimes occurring in preparations made with balsam or dammar dissolved in chloroform: as I never found them in my own preparations made with pure balsam I attribute them to the chloroform. Shortly after I began using Tolu a correspondent informed me that some of his slides were spoilt by a kind of crystallisation, which he described as being like a delicate cobweb. Having noticed a similar appearance in balsamed slides that had been overheated and in consequence the balsam had become brittle, I have sometimes seen the formation of it when cleaning off the superfluous balsam. A sudden change of temperature, such as the heat of the hand, will produce it. The appearance is caused by innumerable fissures permeating the film of balsam. Tolu, if hardened too much, will, no doubt, act in the same manner. Tolu being of slightly higher refractive index than Styrax is useful for many forms, and I hope that the defect may be remedied either by the use of benzole or by making the Tolu less hard.

Dr. G. D. Brown's letter was read as follows:—In the current No. of the *Journal*, in a review of Mr. Busk's "Report on the *Challenger* Polyzoa," it is stated that the use of the chitinous element as an aid in the classification and descriptive geology of the Polyzoa is entirely due to Mr. Busk. Allow me to call attention to Mr. Busk's first mention of the subject—viz, in the *Journal* of the Linnean Society, Zoology, Vol. XV. (1881), p. 357. In this paper he adopts and develops the facts corroborating the opinion of the importance of these organs in this connection; but he himself states that he is indebted for the suggestion to a paper by Mr. A. W. Waters in the *Proceedings* of the Literary and Philosophical Association of Manchester, 1878.

Mr. Crisp said that undoubtedly Mr. Waters should have the credit of priority as acknowledged by Mr. Busk. The review in question, however, was written by so eminent an authority (Prof. Allman) that it had been printed without the thought that any correction could be required.

Dr. Ord exhibited and described some objects illustrating the erosion of the surface of glass when exposed to the action of carbonate of lime and a colloid. From experiments made by Mr. George Rainy, it seemed that when lime was deposited upon glass in the presence of a colloid, the globule it formed adhered so firmly as to require removal by means of an acid. After this it was seen that the surface of the glass was dimmed, and microscopical examination showed that this was due to the presence of numerous little pits, which evidently corresponded to the points of adhesion of the globules, although no chemical substance capable of eroding glass had been employed. Further experiments by the speaker were detailed, showing that he had caused lime to be so deposited by mixing carbonate of potash and chloride of lime in solutions of gum, albu-

-men, glycerin, and gelatin, and that in each case, except that of gelatin, the dimming of the glass from the same cause had been observed. Some slips of ivory and mother o' pearl were also eroded in the same way by the glycerin solution, and it was inferred from this that the substances mentioned had been eroded by purely molecular action. The observation, it was considered, offered an explanation of the effects of boring sponges upon shell and rock, as well as of the phenomena of the similar removal of shell and bone in the process of their remoulding.

The president thought that Dr. Ord's communication was one of remarkable interest which appeared to open up a new matter for promising investigation, and which he hoped Dr. Ord *himself* would develop at greater length in a form for publication.

Mr. J. Charters White mentioned, as bearing upon the subject, the molecular disturbance which took place on the surface of glass in the case of photographic negatives.

Dr. Matthews said there were certain kinds of glass which appeared to undergo spontaneous decomposition; this was particularly noticed in the case of the very old glass found in tombs and causing the iridescence.

Mr. G. D. Brown said that a somewhat similar effect had been observed in the case of old glass in windows; particularly those which faced the south-west.

Prof. Stewart thought that the disintegration of glass which was the cause of the colours referred to, belonged to a different category, as indicated by Sir David Brewster in a paper which he published upon the subject. In examining decomposed glass the primitive surface might be frequently observed to be broken up into concentric films, frequently following definite lines. When this layer breaks off it leaves the surface pitted with spheroidal depressions. There were, he thought, some difficulties to meet in endeavouring to account for all the phenomena by molecular movement, as, for instance, in the case of *Hydractinia arborescens*, where a film of chitin separated the protoplasm of the organism from the incrusted shell. As regarded the boring powers of certain sponges and the removal of lime, he thought that the suggestion of Dr. Ord was very likely to be correct, and that the movement of the heavy molecules of the colloids might, sledge-hammer-like, increase the motion of the molecules of the body acted upon, and finally produce the observed effects.

Mr. Cheshire thought that there was a curious mathematical side to this question as bearing upon the velocity imparted by the stroke between the heavy molecule of the colloid and the lighter molecule of the lime.

Dr. Ord replied to the remarks that had been made, and exhibited a specimen and also enlarged diagrams of a spheroidal calculus of uric acid, found in the kidney of a patient, surrounded by a layer of a chitinoid nature, and showing extensive erosion of the uric-acid nucleus by its colloid investment.

Prof. Stewart mentioned a case of the peculiarly resistent substance of oxalate of lime calculi being similarly eroded.

Mr. J. W. Stephenson read his paper "On a New Catadioptric Illuminator," having an aperture exceeding that of any existing objective—or equal to 1·644 N.A. in flint glass, and 1·512 N.A. in crown glass. The subject was illustrated by diagrams and by the exhibition of the apparatus.

The President thought that all who were in the habit of using high-angled lenses would feel indebted to Mr. Stephenson for giving his attention to this subject, which was one of great practical interest in these days of extended research on micro-organisms. He regarded as of special practical value the power of obtaining black ground illumination with objectives of the largest aperture.

Mr. Cheshire and Mr. Cheyne's paper "On the Pathogenic History of a New Bacillus (*B. alvei*)" was introduced by Mr. Cheshire, who said that attention had been called to a very serious disease which had prevailed amongst hive bees, attacking the larvæ to so great an extent that in some instances whole stocks had been exterminated. The disease was known as "foul brood," from the disagreeable smell which came from the affected hives, and from the idea that it was confined to the larval state. On careful investigation, however, it appeared that the disease was due to a bacillus, and that the bees themselves, including the queen, suffered from it. It was very satisfactory to be able to announce that they had discovered that the disease yielded very readily to treatment, which consisted in feeding the larvæ with a syrup containing 1-600 per cent. of phenol.

Mr. Cheyne followed with a detailed explanation of the methods adopted in tracing out the life-history of the *Bacillus*, and exhibited in illustration a series of tubes and bottles in which its propagation had been carried on. It was not possible to rely upon the shape as determining whether the *Bacillus* was a new form or not, but the completion of a series of experiments and observations enabled him to say that this was a new form, and that it was really the cause of the disease. It had been named *Bacillus alvei*.

Mr. Dowdeswell regarded this communication as one of great interest, and especially remarked upon the fact that this was the only instance he had heard of in which the virus of the disease had been taken in with the food instead of being communicated by inoculation. He felt that they were greatly indebted to Mr. Cheyne for so clearly demonstrating the methods employed for the observation of the development of the organism.

Mr. Crisp said that that was not the only claim which Mr. Cheyne had upon their admiration, as it would be remembered that it was he who had organised the Biological Laboratory at the Health Exhibition, which had proved so great a success.

The President expressed his regret that the hour was so late as to preclude the possibility of further discussion on the paper, in which there were many points of exceptional interest.

Mr. Fowke read a paper "On the First Discovery of the Comma Bacillus of Cholera," illustrating his remarks by photographs and drawings. He showed that the bacillus was known and recognised 35 years ago by two Englishmen, Messrs. Brittain and Swayne.

Mr. Maddox pointed out that it was by the breaking up of the rings discovered by the original observers that the so-called "comma" bacilli were formed.

The President announced that the second conversazione will be held on April 22nd. Sixteen new Fellows were proposed and elected.

## LIVERPOOL ASTRONOMICAL SOCIETY.

THE sixth meeting of the session was held on March 9th, the president occupying the chair. A paper by Dr. Klein was read on the dark spots between Copernicus and Gambart. These spots were only visible under a high illumination, and had, up to the present time, remained an enigma to the observer. Schmidt had reported on them in his work on the moon; but he did not include them in his map, because they were of too evanescent a character, and being only visible when the sun attained a high altitude, and, of course, when the true shadows had departed. They were traversed in every direction by rays, and it was almost impossible to determine their exact positions. Schmidt had, however, always been anxious that their mystery should be solved, and he had urgently commended a close study of their appearances and positions. For a more exact knowledge of the physical nature of the moon, the discovery of the true nature of these spots was of the greatest importance. Respecting his own observations, which had been already reported, he had not been able, during a considerable number of years, to perceive anything that would tend to a decisive conclusion as to the real nature of these formations; but, after many vain efforts, he had been able, only last January, to fix the positions of a number of these spots, so that their identity under high illumination could not leave any uncertainty.

The region E. of Copernicus showed numerous dark and frequently isolated hills, from about 328 English feet in height down to the finest spots, which had the appearance under a high power of isolated masses of rock, and which were only visible under the most favourable circumstances. Quite different was it on the W. and brighter part. There the number of the smallest craters, whose diameter could not exceed 500ft., was quite enormous; the minute craters between Copernicus and Eratosthenes appearing of great size by comparison. On January 25, 1885, he was induced by the wonderful clearness and tranquility of the air to scrutinise them very carefully. At this time the remarkable crater, indicated by Schmidt as *m*, had already shown its grey nimbus very distinctly, and the whole area towards Gambart C appeared perforated, like a sieve, with the smallest craters. He had been observing a faint dark streak which appeared to be sweeping over that region from S.W. to N.E., when, at 7h. 3m. p.m., there suddenly came forth a small black spot at the S. border. It appeared in the region where numerous craters of the very smallest kind exist, but could not be identified with one of them, and it certainly had not been visible a quarter of an hour earlier.

Mr. W. S. Franks, F.R.A.S., was glad to see that Mr. Gage was taking up star colours, which, he thought, was an interesting but neglected branch of astronomy. Ever since the time of Sir W. Herschel the colours of *double* stars had been carefully registered to the almost utter exclusion of naked eye stars which did not happen to have *comites*. The Rev. T. W. Webb was, he believed, the first to call attention to the colours of single as well as of associated stars, and it was by his advice that he had made some observations of the colours of nearly all the naked eye stars visible in these latitudes between 1877 and 1878. He intended, probably next winter, to form a new catalogue of star colours, and proposed that the objects should be simultaneously observed.

The president said Dr. Copeland, of Dun Echt, had been kind enough to call his attention to the occultation of Jupiter's II. satellite by its own shadow on the night of February 19th. The evening, which began exceedingly clear, had, however, turned foggy later on, and he missed the most important part of the observation. He presented a list of 32 red stars, which, so far as he was aware, were not included in Birmingham's or any other red star catalogue. Several of them had been discovered by photography. In the zone at present being photographed, the great nebula in Andromeda occurs. The nebula appears much more sharply defined on the *p.* side, and several dots appear on the negative *s. p.* the nucleus, which are probably additional stars; though the difficulty of determining which were stars and which were specks on the plate was very considerable, and it was quite possible that some of the stars entered in the drawing would turn out not to be stars at all. On the *s.f.* side of the nebula a star of 6·5 mag. is buried in the nebulosity, which seemed more diffused at this part, the north being very sharp. The limits of the nebula, as laid down by Argelander, and those on the negative agreed very fairly, with the exception of the *s p.* portion, which seemed to be less in the photo. than in the telescope. The nebula was, no doubt, deficient in photographic light; whilst the Orion nebula, on the contrary, very quickly penetrated the sensitive film. The equivalent star magnitude of the centre of the nebula varied in Pickering's photometer from 6·1, on the 17th of September last to 4·8 on the 5th November, whilst the photographic magnitudes of both these periods was 8·3.

Prof. Piazzi Smyth, Astronomer Royal for Scotland, described some interesting phenomena attending the disappearance of Aldebaran at the last occultation. At 5 p.m., the moon being high, up in the sky, and with the star close outside its dark limb, formed a very pretty but faint group in the little telescope, for the sun was still shining. Unfortunately the air, although quite free from actual cloud, was so full of illuminated coal smoke as to quite conceal any trace of the dark limb whereat the star was to be presently occulted. Presently, while he was still earnestly looking, the star disappeared, so suddenly and completely that he called to his assistant "mark," with the utmost confidence, though, fortunately, without taking his eye from the telescope. Almost immediately he saw the star again for 2·6 seconds, when it disappeared once more, and this time finally. As to the heretical feature of seeing two immersions of the star, he gave it simply as it occurred; though he would have had more confidence in its being a reliable observation if the dark limb had, at the time, been visible, or if the telescope had been larger and under the protection of the dome on so gusty and inclement a night.

In submitting a voluminous report from the planetary section on Saturn, Mr. W. S. Franks said few prefatory remarks were needed. He had issued a circular last October directing the attention of the members to such salient features as might be best studied during the then approaching and unusually favourable opposition. Thirty-eight sketches of the planet were given in, accompanied by careful notes by the observers, who included the Revs. S. H. Saxby, T. Perkins, J. Bone, and Messrs. J. M. Offord, G. T. Davis, S. M. B. Gemmill, J. Ellis, E. Miller, and A. F. Miller, of Toronto.

Mr. R. G. Leigh described an observation of the dark transit of Jupiter's IV. satellite. At 10 o'clock on the night of the 27th February the satellite was well on the disc of Jupiter, and just below the S. belt. It appeared in his 6½in. Calver equatoreal as a conspicuous dark spot of a dark brown or chocolate colour, many shades darker than the belt, which was of a light reddish hue. When the shadow immerged the contrast in colour was very apparent, the satellite being still of the same tint, whilst the shadow was almost black.

Mr. R. C. Johnson, F.R.A.S., in observing the same transit through one of Cooke's 7in. refractors, had been particularly struck with the dark colour of the satellite. It could, in fact, only be distinguished from its shadow by its smaller size and the position it occupied on the face of Jupiter. Five large photographs were presented to the society by Mr. A. A. Common, and a monograph of the Orion nebula by Mr. W. S. Franks. A unanimous vote of thanks was accorded to the donors. Eleven gentlemen were elected members, and 11 candidates were proposed.

THE American production of Bessemer steel last year amounted to 1,538,355 tons, being a decline of 116,272 tons from the figures for the previous year. The American production of rails was 1,140,932 tons.

As far as can be at present estimated, there were about 3,572,155 tons of pig iron made in Germany last year.

# SCIENTIFIC NEWS.

WE learn from Dun Echt Circular No. 93 that M. Raoul Gautier, of Geneva, has communicated some interesting particulars respecting the return of Tempel's periodic comet 1867 II. It appears from M. Gautier's calculations that the disturbing action of Jupiter, in the interval 1879 to 1885, will retard the comet's approach to the sun by 148 days, besides considerably enlarging the orbit while decreasing its eccentricity. As the comet will not approach the earth within one and a half times the distance of the sun, it is doubtful if it will become visible even in the most powerful telescopes. The following ephemeris gives its calculated place for Berlin midnight (11·6 G.M.T.):

| | R.A. | N. Dec. |
|---|---|---|
| March 21·5 | 12h. 5m. 12s. | 18° 28·4′ |
| April 10·5 | 11h. 49m. 24s. | 18° 57 7′ |

M. Borrelly, of Marseilles, discovered another minor planet on the evening of the 13th inst. Its position at 9.7 on that evening was R.A. 11h. 6m. 13s., N. Dec. 7° 9′ 17″. This is the thirteenth minor planet discovered by M. Borrelly, and, according to the *Times*, is the first discovery amongst these bodies during the present year. If so, it will reckon as No. 245; but we believe that Mr. Pogson, at Madras, discovered the first this year, whilst searching for Isis on the 6th of February.

Observers in the West of England will have a chance of observing the occultation of Aldebaran on March 21, as it will have an altitude of 4½°.

The Royal Society of New South Wales offers prizes for the best communication on each of the following subjects, by way of encouraging original research: — The Anatomy and Life-history of the Echidna and Platypus; the Anatomy and Life-history of Mollusca peculiar to Australia; and the Chemical Composition of the Products from the so-called Kerosene Shale of New South Wales. The communications must be sent in not later than May 1, 1885, and provided it is of sufficient merit, the best on each subject will be awarded the society's medal and £25. The subjects for 1886 are: — On the Chemistry of the Australian Gums and Resins; on the Tin Deposits of New South Wales; on the Iron Deposits of New South Wales; and List of the Marine Fauna of Port Jackson, with descriptive Notes as to Habits, Distribution, &c. The subjects for 1887 are:—On the Silver Ore Deposits of New South Wales; Origin and Mode of Occurrence of Gold-bearing Veins and of the Associated Minerals; Influence of the Australian Climate in producing Modifications of Diseases; and On the Infusoria peculiar to Australia. For each subject the prize is £25 and the Society's medal, and the communications must be addressed to the hon. secs. at the Society's house, Elizabeth-street, Sydney, and reach them not later than May 1 in each year. The Society is fully sensible that the money value of the prize will not repay an investigator; but it hopes that the honour will be regarded as a sufficient inducement and reward. The competition is open to all, but a prize will not be awarded to a successful competitor should he happen to be a member of the Council. Communications to be successful must be either wholly or in part the result of original observation or research on the part of the contributor.

The Minister of Education in France has appointed a commission to report on the opportuneness of extending the decimal system to astronomical distances and time.

A plan for the transmission of the mails between Paris and London by the pneumatic process, devised by a M. Berlin, is attracting considerable attention. The pneumatic tubes or subway would be laid down along side the existing railways for convenience sake. The total distance between the two capitals is 475 kilometres (295 miles)—viz., Paris to Calais (rail), 184·5 miles; Calais to Dover (Channel), 24·2 miles; and Dover to London (rail), 86·3 miles. The pneumatic subway would be constructed of cast-iron pipes of 15·3in. in diameter and 13ft. lengths, connected by means of indiarubber joints. This arrangement is claimed by the inventor as giving great flexibility and elasticity to the whole, and of making it water-tight besides. The carriage suggested is composed of a wire frame covered by a sheet of asbestos cloth with a metallic warp. This covering would have a kind of metallic brush coating, to enable the compressed air to dilate to a certain extent around the truck and cool the latter, thus counteracting the heat produced by the friction. The truck would travel the distance between the two capitals in one hour, and a truck could be despatched every ten minutes. An engine of from 20 to 30 horse-power would be sufficient to produce the required vacuum.

"F.R.S.," writing to the *Times* in reference to a recent colliery disaster, expresses astonishment at the neglect of owners to avail themselves of the simple means which science places in their hands for enabling explorers to carry out their humane work with comparatively little danger from suffocation by the deadly afterdamp. Mr. Lindsay's plan for placing iron nails in the mouth is practically valueless, as the quantity of carbonic acid gas thus absorbed is inappreciable; but a respirator filled with cotton-wool and slaked lime or caustic soda, or. better still, a cylinder filled with the same material carried on the back with a flexible breathing tube and mouthpiece, will enable an explorer to remain for some time in an atmosphere charged with choke-damp which would be at once fatal if inspired directly.

A Skrivanow battery, which is contained within two small boxes 10in. long, 8in. wide, and 6in. high, is said to be capable of supplying an arc lamp of 600 c.p., or 75 small incandescent lamps. It is the chloride of silver form of the Skrivanow battery, and a large number of cells can be put into a small compass. Extraordinary statements about this battery may be expected, and one of the electrical periodicals warns local authorities to "consider what is being done to provide at far less than the cost of gas a more brilliant and beautiful illuminant."

Prof. Ayrton having been appointed to the chair of Physics at the Central Institution of the City and Guilds of London Institute, Prof. Silvanus P. Thompson has succeeded him as principal and professor of physics at the Finsbury College.

Dr. Venable contributes a paper to the American Chemical Society, in which he shows that spring water which had passed through 200 yards of galvanised iron pipe took up 4·29 grains of zinc carbonate per gallon. The French Ministry of Marine prohibited the use of galvanised-iron tanks on board men-of-war some time ago; but they are extensively used in this country, and so are zinc-lined cisterns. It would be interesting to learn how much zinc is contained in our cistern water.

Prof. Charles E. Munroe reports in the *Journal* of the American Chemical Society a case of spontaneous decomposition of "explosive gelatine." The liability of this substance to decomposition cannot be too widely known, as it is now largely used for blasting purposes.

An electrical exhibition will be held in the galleries of the Paris Observatory, under the auspices of the Société Internationale des Electriciens. It will be inaugurated on the 21st inst. by M. Grévy, president of the Republic.

The photographic work is being successfully continued at the Paris Observatory by MM. Paul and Prosper Henry. One of their latest productions is a fine photograph of the cluster in Perseus, showing the stars down to the 13th magnitude. The negative was obtained in 50 minutes with a 6·3in. object-glass of 83in. focal length; it has been enlarged four times, and reproduced by helio-engraving. These copies are on a scale of 5in. to a degree, and contain 509 stars.

**Soluble Glass.**—To apply soluble glass for the preservation of porous materials, take a solution of silicate of potash of 35° Baumé, dilute it with twice its weight of water, paint with a brush or inject with a pump, give several coats. The *Pottery and Glassware Reporter* says:—"Experience has shown that three coats applied on three successive days are sufficient to preserve the materials indefinitely, at a cost of about 15 cents per square yard. When applied upon old materials, it is necessary to wash them thoroughly with water. The degree of concentration of the solutions to be used varies with the materials. For hard stones, such as sand and freestones, rock, &c., the solution should mark 7° to 9° Baumé; for soft stones with coarse grit, 5° to 7°; for calcareous stones of soft texture, 6° to 7°. The last coating should always be applied with a more dilute solution of 3° to 4° only."

# LETTERS TO THE EDITOR.

*[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.]*

*All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, 332, *Strand, W.C.*

*All Cheques and Post-office Orders to be made payable to* J. PASSMORE EDWARDS.

⁂ *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks a vice from whence great inconveniences derive their original."
—*Montaigne's Essays.*

## THE TOTAL SOLAR ECLIPSE IN SEPTEMBER, 1885.

[23950.]—So many inquiries have been addressed to me recently by readers of the ENGLISH MECHANIC resident in New Zealand, and so much interest appears to be taken in reference to the forthcoming eclipse of the sun, the central line of which passes through that colony, that I have thought it worth while to compute the circumstances for various places mentioned below by the partially graphic method which I have recently devised, and which is so admirably adapted for the purpose. A *total* solar eclipse is a rare and unique phenomenon in England; such an event has not occurred for many generations, and many generations more must occupy our places before there will be an opportunity of witnessing such a spectacle. The inhabitants of New Zealand may therefore congratulate themselves that they are permitted to behold a sight which the oldest inhabitant of the mother country has been precluded from seeing, and it is to be hoped that some useful additions to our knowledge in regard to the constitution of the sun, its chromosphere and corona, may be the outcome of the observations which scientific people at the Antipodes may make on this auspicious occasion.

I proceed, then, to give the following as the times and angles which mark the course of this eclipse at different places:—

At Wellington, lat. 41deg. 20min. South, geographic; long. 11h. 39min. East.

| | h. | m. | s. | |
|---|---|---|---|---|
| The eclipse begins at | 18 | 40 | 15 | Mean astronomical time at Wellington. |
| ,, middle ,, | 19 | 44 | 45 | |
| ,, ends ,, | 20 | 56 | 20 | |

Duration of totality, 1min. 53sec.

Angle from vertex at beginning, 50deg. towards West.

Angle from vertex at ending, 107deg. towards East.
For direct image.

At this place the eclipse is *total.*

At Castle Point, lat. 40deg. 54min. South, geographic; long., 11 hours 44min. 56sec. East.

| | h. | m. | s. | |
|---|---|---|---|---|
| The eclipse begins at | 18 | 45 | 47 | Mean astronomical time at Castle Point. |
| ,, middle ,, | 19 | 52 | 0 | |
| ,, ends ,, | 21 | 2 | ·0 | |

Duration of totality, 1min. 58sec.

Angle from vertex at beginning, 62deg. towards West.

Angle from vertex at ending, 106deg. towards East.
For direct image.

At this place, also, the eclipse is *total.*

At Masterton, which is not very remote from Castle Point, the eclipse begins at 18 hours 44min., and ends 21 hours 0min. Castle Point mean astronomical time. The eclipse will be total, and the angles the same as those at Castle Point (nearly). The time of commencement and end of totality may be computed by subtracting and adding the semi-duration of totality from and to the time of the middle.

At Napier, lat. 39deg. 30min. South, geographic; long. 11h. 48min. East.

| | h. | m. | s. | |
|---|---|---|---|---|
| The eclipse begins at | 18 | 47 | 20 | Mean astronomical time at Napier. |
| ,, ,, middle ,, | 19 | 54 | 50 | |
| ,, ,, ends ,, | 21 | 5 | 40 | |

Magnitude = 0·98—i.e., 98 parts of 100.

Angle from vertex at beginning 58deg. towards West.

Angle from vertex at ending 105deg. towards East.

For direct image.

At this place a thin rim of the solar disc will be seen on the *upper* part of it.

At Dunedin, lat. 45deg., 50min. South, geographic; long. 11h. 22min. East.

| | h. | m. | s. | |
|---|---|---|---|---|
| The eclipse begins at | 18 | 30 | 40 | Mean astronomical time at Dunedin. |
| ,, middle ,, | 19 | 35 | 20 | |
| ,, ends ,, | 20 | 42 | 20 | |

Magnitude = 0·94—i.e., 94 parts out of 100.

Angle from vertex at beginning 67deg. towards West.

Angle from vertex at ending 109deg. towards East.

For direct image.

At this place a thin rim of the solar disc will be seen on the *lower part* of it.

The inhabitants of Australia will only see this eclipse as a very partial one, and the only place for which I have obtained results is Sydney. The mists and fogs of the rising sun will, most probably, prevent any distinct vision of it; but it will be interesting to see the sun emerge out of the ocean, partially eclipsed, with considerably more than half of the *lower* part of his globe hidden, or rather *cut out* by the disc of the moon, if the weather should prove favourable. Twenty minutes, however, will have elapsed beyond the time of greatest phase at the instant of sunrise.

At Sydney, lat. 33deg. 51min. 41sec. South, geographic; long. 10h. 4m. 51s. East.

| | h. | m. | s. | |
|---|---|---|---|---|
| The eclipse begins at | 16 | 57 | 20 | Mean astronomical time at Sydney. |
| ,, middle at | 17 | 50 | 0 | |
| ,, ends at | 18 | 51 | 0 | |

The sun rises at 18h. 10m., and the magnitude at greatest phase, which, of course, will be invisible, will be 0·85, or 85 parts out of 100.

Angle from vertex at beginning 40deg. towards W.

,, ,, ,, ending 142deg. ,, E.

For direct image.

**James Pearson, M.A., F.R.A.S.**

Fleetwood Vicarage, March 12.

## BESSEL.

[23951.]—THE question of the shadow of Bessel being double-peaked was discussed some time ago, and in the *Astronomical Register* for January, 1884, there is a paper by Mr. T. Gwyn Elger on the subject. It may be worth recording that on February 20, 1885, 8h. to 9h. 15m., I saw it with two considerable peaks, the crater being full of shadow and the terminator on Eudoxos. The edge of the shadow was somewhat ragged, and it was rather broader on the sonthern wall of Bessel than on the northern. Its shortest length, half-way between the peaks, was about half the diameter of the crater. As it grew shorter it still preserved the two peaks, and was thus seen up to 9h. 15m. I made two sketches, one at 8h. 25m. the other at 9h. 15m. I have now seen Mr. Birt's sketch which led to the discussion, and which was also made at morning illumination with the terminator on Eudoxos. The other sketches mentioned were, I believe, made at sunset. My sketch does not show the horns so long as they are in Mr. Birt's, or the hollow between them so deep. **M. A.**

## OCCULTATION OF ALDEBARAN.

[23952.]—THE disappearance at the occultation of Aldebaran on February 22 was not seen, owing to clouds, but a few minutes before the reappearance they cleared away, leaving the moon perfectly clear in a blue sky. The moon was crisp and bright, though at moments there was a little passing mist. The edge was rippling gently at first, but scarcely at all when the star appeared. Its appearance was very sudden, and its progress till its final clearance from the limb very rapid. The first thing seen was half of two diffraction rings, which suddenly sprang into view; in about two seconds more the star itself appeared equally suddenly, and in six or eight seconds more it was perfectly clear from the limb. When the star itself appeared two wings started into view from it, and remained until it was quite clear from the limb. Then it assumed its ordinary appearance, with the diffraction rings surrounding it equally on all sides. When the star first appeared it was a very deep crimson. I believe this crimson hue was also visible on the two rings that preceded it, and that it became much more intense as the star appeared; but whether it was on the rings as well as the star I am not quite sure—the star came into view so rapidly after the rings, and the first impression was of an intense crimson. A few seconds after, before the star was quite clear, I think there was a shade of green; but, if so, it was but slight. **M. A.**

## JUPITER—DARK TRANSIT OF SATELLITE III.

[23953.]—WE have at last been favoured with some remarkably fine observing weather. The prevailing wind has been from the east, and during it, as I find frequently to be the case here, definition has been very good. Several changes have taken place in the markings of Jupiter since last season: the great south belt seems to me rather paler in colour, and the great north belt somewhat darker. The outline of the Great Red Spot is still very plainly visible with my 8½in. Calver as a pale red oval line; it is preceded in the same latitude by a small dusky grey spot, and is followed at an interval of about 1¾ hour by a dark crimson streak, which is followed after 1¼ hour by a small crimson spot, and this again by another somewhat longer. These three last lie just within the southern edge of the great south belt. About 3½ hours before the Great Red Spot reaches the central meridian, a dusky patch a little north of the Equator crosses the c.m. Several brilliant spots are to be seen in the Equatorial regions, and a long wavy bright streak in the South Polar regions.

On March 13, on going to the telescope at 19h. 30m. to make a drawing, I noticed a round grey spot, just within the north edge of the great North red belt. This I suspected to be a Satellite, as it was not dark enough for a shadow. On reference to the *Nautical Almanac* my suspicions were confirmed, as I found that III. was in transit. Thin clouds scudding before a high wind, at times blotted out Jupiter, but I saw the Satellite whenever the sky was clear until 22h. 10m., when clouds came up, and when they passed off at 22h. 25m. I could no longer detect the Satellite, which, however, at 22h. 30m. was seen bright as it approached the limb. The shadow of III. came on at 21h. 9m. and looked perfectly black, the Satellite all the time being dark grey, and not black.

Shaftesbury. **Thomas Perkins, M.A.**

## SATURN.

[23954.]—TO-NIGHT, during exceedingly fine air, I was surprised to see (with 800 on the 10in. dialyte) a perfectly sharp, fine, black line, in place of Encke's division on the outer ring. I was unprepared for, and not looking for this line, so that there was no mistaking the appearance which was seen in both ansæ, and nearly all round the ring.

I am very glad to have this to add to my former remarks, and it would seem, in conjunction with my late observations of the bright inner edge of the outer ring, which was absent on this occasion, to favour the theory of variability. The night, however, was exceedingly fine.

**Herbert Ingall.**

Champion-hill, S.E., March 14.

## "A PLEA FOR GOOD MANNERS."

[23955.]—I HAVE read Mr. Ledger's letter in your issue of March 6th, and heartily concur with him in his wish to see personalities avoided, and a more serious tone adopted in criticising the grave evils of endowment hunting. I am fully willing to acknowledge differences of taste as to what is dignified and proper language to use in a scientific periodical, and to own that Clerk-Maxwell and De Morgan and other men of great weight have indulged a curious sense of the ludicrous without injuring their usefulness. But in an uphill battle, such as those who oppose the endowment party are attempting to fight, it seems to me that one cannot adopt too serious and Parliamentary a tone.

In remonstrating recently with a friend who feels quite as I do about the injury to science which is caused by the search after endowment, but who allows his indignation frequently to find vent in strong and not always dignified language, he replied to me: "I wonder how far Lord Randolph Churchill would have secured a hearing if he had adhered to the polite phrases you recommend?" My friend seemed to hold that we had arrived at an age when only slang will arrest attention. I do not agree with him. I think that, whatever may be his audience, an earnest man will always arrest attention, and his opinions will in time be examined. If he has a difficult case to argue, where the self-interest of his hearers is thwarted—and it may be presumed that at first they will be against him—he is likely to lose ground by using a single word which his opponents can take exception to. They will devote their time to criticising his language rather than to answering his arguments; and he will find that a large proportion of his hearers are so weak, that they will be led to believe that making an undignified joke is a crime, while helping a job is not. **A. C. Ranyard.**

## VIOLINS.

[23956.]—IN replying further to "Orderic Vital" (23916), I may add that excellency in violins is not confined to any special form of arching or outline, or to any exact thickness of wood, although it is now definitely known between what extremes of thickness success may be looked for. It may, however, be stated generally that the high model, by which is understood an elevation of more than about ⅝in. in the back and belly, conduces to a sweet and mellow tone without much power; and in the best instruments of this class there is often found a quality of tone more or less wanting in the majority of flat models. Some of the violins of Steiner are so high as to appear quite "tubby," and the tone is described by Davidson as being pure and liquid, but not powerful, which renders them particularly well adapted for use as chamber instruments. The makers who followed the Amatis, the chief of whom was Stradivarius, gradually found out that the flat model was the best for the production of an intense, deep, full, and broad tone, and that the curvature should be gentle and easy, and free from any abrupt elevation. Violins of a flat model are often found to possess power at the expense of quality. The most renowned makers combined these two desiderata with more less success; but to Stradivarius belongs the honour of having combined in the highest degree all the different qualities which can be desired in a violin. His finest instruments are described by Davidson as "possessing the following esteemed qualities: delicacy, mellowness, free power, penetrating brilliancy, and roundness of tone." The character of the curves vary very much in the high models, but in the finest Strads they are gentle and harmonious with an elevation of about ½in. The accompanying sketch is reduced from a full-sized working drawing of a Strad of the most finished elegance in a recent work, entitled "Violin Making, as it Was and Is," by Edward Heron-Allen. The curve is that of the belly lengthwise, and it will be noticed that there is rather more dip at the neck end, A, than at the tail, B. It is, however, difficult in a reduced drawing to catch the exact character of a curve which cannot be drawn with compasses.

The difficult question as to what constitutes the superiority of one violin over another remains yet to be solved. It cannot altogether be in form and workmanship; otherwise copies would more frequently be equal to the originals. One of the most important points (if not *the* most important) is, undoubtedly, the quality of the wood. We know that old makers paid great attention to this, and that sometimes they only used wood cut from the south side of the tree. Many of the Cremona fiddles have pieces added on to the widest part of the back, in order to utilise wood of good quality, which would otherwise have been too narrow. The climate of Italy may also be specially suitable for the seasoning of the wood. We have heard a good deal lately about the Italianising of the human voice by breathing artificial Italian air. Possibly we may next hear of the Italianising of wood for fiddle makers! It is now well known that violins made from wood artificially seasoned by heating or steaming, are, in the long run, a complete failure. Another most important point is the suitability of the back and belly to each other. Each may be good in themselves, but when unsuitably mated (like human beings) discord, instead of harmony, prevails. Every piece of wood gives out some note, and it has been found that there is a difference of about one note between the back and belly of those of Strad.'s best fiddles which have been dissected. It has also been found that the mass of air in the best instruments of Strad. and Guarnerius gives a note of 572 vibrations in a second. There is, however, no evidence that these and similar theories were known to the old makers. There is considerable difference of opinion as to the theoretical knowledge which they possessed. There are the *premeditation* and the *consequential* theories. The author of "How to Choose a Violin" states the following facts in favour of the latter: "That the Cremona neck was shorter than at present; that the standard of pitch was much lower; that, therefore, the tension of the strings and general pressure was much less; that the old instruments well bear the additions of long necks, thicker strings, and much increased strain; that, being strong enough to do so now, they must originally have been much too strong in proportion to the then existing strain to produce the best tone; and that the makers consequently could not have known the full capabilities of their instruments, as they did not realise the amount of strain they would be brought to bear." It should be clearly understood that fiddle making is as much an art as it is a science, and the old makers were artists in the true sense of the word. While some give them credit for a theoretical knowledge more complete than that possessed by any of their successors, there are others who think, as I am inclined to do, that their knowledge of mathematics and acoustics was of a very limited description, but that they combined perfect workmanship with a correct judgment in the selection of wood acoustically good; that they were able to tell intuitively by an artistic eye and touch, and perhaps by some rough and ready experiments, the suitability of bellies and backs to each other; that they were able by the same means to adjust the thickness to suit the varying qualities of the wood and the curvature of the instrument; that, having found out that a low model, with a gentle and flowing curvature, gave the best results, they then in all other matters simply strove to please the artistic eye. It is related of Turner, the painter, that, on first reading some of Ruskin's elaborate criticisms of his works, he said: "That man puts thoughts into my head that I never had before." Possibly the old Cremona makers might make a similar remark could they read some of the learned theories on the construction of their instruments. Sometimes a cheap and roughly-made fiddle turns out to be very good, but not often. Scarcely any manufactured article varies so much in price as the fiddle, ranging as it does from 2s. 6d. to £1,000. The following extract from Mr. Heron-Allen's book is interesting, as showing the actual cost to the manufacturer of the common shop-window fiddles, which are sold at prices varying from 10s. to 30s.: "The manufactories at Mirecourt turn out many thousands of crude 'noise boxes' annually, labelled, as a rule, "Antonius Stradivarius," "Joseph Guarnerius," &c. These are extraordinary for their quantity and cheapness. M. Gallay, in his report on the Vienna Exhibition, noticing the establishments of Thibouville-Lamy (who have a London house in Charterhouse-street), quotes, as follows, the actual cost of the manufacture of one of these fiddles: Wood for back 2d., wood for belly 2d., manufacture of same 1½d., wood for neck ½d., making same 1½d., finger-board (stained) 2d., cutting 1½d., moulding back and belly 12½d., varnish 10d., fitting-up, strings, tail-piece, bridge, &c., 7½d.; total 4s. 2d. M. Gallay goes on to say that he heard such a fiddle as this, chosen from a number of similar ones and carefully mounted and strung and played, the tone and results obtained from which, at a concert in Vienna, were most satisfactory."

**A Country Parson.**

## VIOLINS.

[23957.]—I FIND a great improvement in the tone of my violin by rubbing the strings once or twice a week with neatsfoot oil. I put my first finger to the neck of the bottle containing the oil, and rub the strings over from tail-piece to nut, until all the strings are moistened. I generally do it when I have done playing for the night; and the next time I require the instrument I wipe the strings before commencing. Some of "Ours" please try it and report results. I have tried other oils, but never found them make the same improvement.

**T. R. S.**

## A NEW METHOD OF FORMING CRYSTALS BY PLAITING.

[23958.]—YOUR report of a meeting of the Liverpool Science Students' Association on page 7 reminds me that a new process of plaiting is lying idle on the table of the inventor of the pupil-photometer, which I described in your last volume, and this process is lying unused because publishers do not care to publish a new book on crystallography while the study of that science is confined to so few.

After a careful analysis of the zones of the primitive forms of mineral crystals, Mr. Gorham has discovered that models of all may be formed by calling in the aid of the ordinary plait of three or four fillets.

Fig. 1 represents the ordinary plait of three fillets. In this we notice that the fillet A passes twice over B and twice under C; the fillet B passes twice under A and twice over C; the fillet C passes twice over A and twice under B.

Having noticed how the fillets intersect, we unravel them, mark them with the same numbers, and arrange the fillet C at right angles to the other two (Fig. 2). The mark – before a number implies that in plaiting that number goes under the same number which has not the minus sign. Plaiting according to the way indicated we get a *cube*.

Having by this simple process formed a cube, it is to see that the process may be extended to any form having the same number of faces, edges, and solid angles; and, further, the process may be extended to forms having 8, 12, or 24 faces.

Now take a plait (similar to Fig. 1) of four fillets, and going through the same process we get Fig. 3. The plans 11 and 12 are repeated to get starting-points and to lock the plates. We obtain a second cube, and from these two cubes we may obtain the primitive crystalline forms. I will now mention a few of these forms, and reserve a few of the more complex for another letter, if the Editor will be kind enough to insert it for me.

*Cube.*—Bounded by six square faces—

$$\angle \text{ of inclination of faces} = 90^\circ$$

$$\therefore \text{plane of } \angle a \text{ of faces} = 90^\circ$$

The cube is an intermediate form betweeen the obtuse and acute rhombohedrons A formula, which enables us to find the plane ∠ *a* of a cube when ∠ of inclination of lanes A is given, enables us to find the plane ∠ *a* of any rhombohedron.:

We have—

$$\frac{1}{2\sin.\frac{A}{2}} = \cos.\frac{a}{2}$$

But—

$$A = 90^\circ;\ \tfrac{1}{2}A = 45^\circ$$

$$\angle \sin.\frac{A}{2} = 9{\cdot}849485$$

$$\therefore \angle \frac{1}{2\sin.\frac{A}{2}} = 9{\cdot}849485$$

$$\therefore \angle \cos.\frac{a}{2} = 9\ 849485$$

$$\therefore \frac{a}{2} = 45^\circ$$

$$\therefore a = 90^\circ$$

*Right square prism*, bounded by four oblong and two square faces.

L of inclination of faces = 90°
Plane angles = 90°

Six planes, twelve edges, eight solid angles.

To obtain this, therefore, we alter Fig. 2 into Fig. 4, and plait according to the indications.

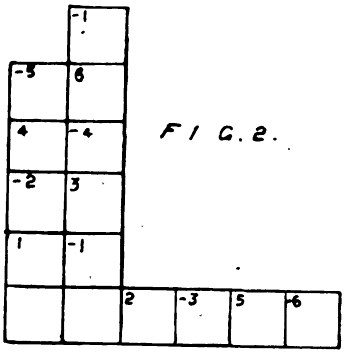

FIG. 2.

FIG. 1

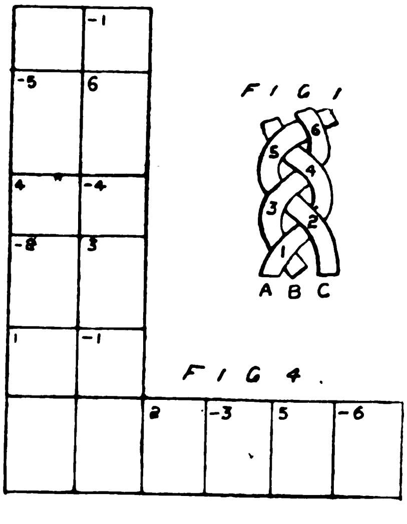

FIG. 4.

I have no doubt that from this imperfect description many readers of the "E. M." will be able to understand a portion of what I mean. As Mr. Gorham has kindly placed his manuscript in my hands, I shall be able to extend this letter in future communications. But as a figure will be necessary with most of the forms I mention, I will endeavour only to mention typical forms. By far the best material for making the models of is glazed cambric, and I do not hesitate to say that any reader will find the time he may spend in making the models well repaid by the beauty of the result. The diagrams inclosed are not very accurately drawn ones; but I hope they will be sufficient to convey an idea of my meaning.

Park House, Tonbridge. **E. A. Tindall.**

## LATHE MATTERS.

[23959.]—MR. WENHAM (23946) may assume that which I do not say; but it is rather an anomaly on his part to state that the best makers true up their mandrels by means of diamond tools, and afterwards that there is no need for such a process, because they can be hardened perfectly true.

I have not personally attempted to harden a mandrel for many years; but I have old and tried workmen whom I taught myself, and as I pass their lathes it is a pleasure to observe how beautifully true to the eye a new mandrel will appear on its first trial after being hardened; but the application of the finger nail destroys this illusion, and although by many it is possible this would be considered near enough, it has to pass the ordeal I have previously mentioned to come out with that degree of perfection which it has always been my study to obtain.

If Mr. Wenham has indeed "made mandrels innumerable, from the heaviest to the smallest," it is very remarkable that he should give such directions as he does for the hardening of our traversing lathe mandrels. When brought to book for the address of "some of our best lathe makers who now prefer to true up their hardened steel mandrels by a diamond splinter," it is remarkable again that Mr. Wenham evades the question.

We all know that it is possible to use a diamond for such a purpose; but the diamond so frequently breaks or gets loose, and the cut taken is so small, that no one would think of using it when a 2s. 6d. emery wheel answers every purpose quickly, safely, and cheaply.

As "Vulcan" has also pointed out, Mr. Wenham is altogether wrong in imagining that a revolving V-cutter or V-lap wheel produces a distorted thread—there is no difference between a thread so produced and that of an angular tool in the slide-rest; but there is this great advantage—that the fixed point tool does not produce a cut of its own full angle unless it is centred exactly and put in on a true radius of the cylinder which is being screwed; with the revolving cutter the cut is always upon the line of centres, and therefore cannot go wrong. This is why, in modern steel standard taps and other tools, the revolving grinder has been adopted.

Mr. Wenham is, as "Vulcan" explains, all wrong, because he imagines the contact between a revolving cutter or grinding wheel to be a surface. The contact is a line not a surface, and the convexities of the angular spiral thread and of the cutting wheel cause them to abundantly clear each other as the cylinder revolves; the case is not, in fact, the same as that which he argues from.

Mr. Wenham's remarks upon the model mandrel are equally at fault; it is well established that a screw cannot be used to centre accurately with: if such an accurate screw were made the first bruise on the end of the mandrel would spoil it. Dr. Edmunds intentionally leaves his screw rather loose, and makes the cylinder base produce the centring and prevent eccentric variation: the width of the face is necessary to prevent angular variation; but, of course, for less perfect interchangeability, a face zone of smaller diameter might be used. This is a mere question of degree, as has already been shown by other writers besides

Griffin Works, Norwich. **Edward Hines.**

## LAMINATED ARMATURES.

[23959*.]—I IMAGINE that the laminated armature condemned so strongly by Mr. Chaster in his article upon "Electromotors" is the one described by me on page 136, Vol. XL., of the ENGLISH MECHANIC. In that case, I may state that it in no way resembles Mr. Jones's patent laminated H-armature, nor are either of the types of armature a "clumsy imitation of a Siemens."

I am not surprised to read that the armature was difficult to wind, and that sufficient wire could not be wound upon it, as I am well aware that successful winding of armatures is only obtained by long practice, and it is of rare occurrence that an amateur electrician makes a good job of his first two or three armatures. The fact that the strips of iron became loose, and so destroyed the insulation of the coils, is only to be attributed to neglect in not properly tightening the nut upon the spindle, such strips of iron requiring at least 1in. of compression before the armature can be safely tight, and then it is a moral impossibility for the discs to shift during rotation.

It is evident to all practical electricians that the old solid H-armature contains too much iron either for a motor or generator, and, therefore, the reduction of the mass of metal by lamination has a three-fold advantage, in that it provides an increased surface in actual contact with the air, so keeping the coils and core perfectly cool; also that such lamination prevents to a great extent the circulation of Foucault or "eddy" currents," and thereby increases the efficiency of the machine, while in the Jones's patent armature exactly the same amount of wire may be wound upon the core as on the same size of solid H-form.

**Fredk. Walker.**

## THE FUTURE OCCULTATIONS OF ALDEBARAN

[23960.]—A reference to the *Nautical Almanac* of the present year shows that eleven occultations of Aldebaran take place in 1885; and out of this number four are recorded as being visible at Greenwich. Much attention having been bestowed on that which occurred on Feb. 22, it is probable that many observers will await with interest the succeeding one, which is set down for March 21. It is to be feared, however, that any expectations in reference to this phenomenon will end in disappointment. The moon will be sinking too low in the west at the time of immersion, whilst at the time of emersion the star will have actually set. In any case, the fogs and mists of the horizon will seriously interfere with any accurate observation. It commences at 11h. 43m. p.m., and ends at 12h. 32m. a.m., as seen at Greenwich. The occultation on April 17 will be wholly invisible in Great Britain and Ireland. None will take place in May or June; but there is one which takes place on July 8, to which I desire to call the attention of amateurs. It occurs in the *daytime*—in fact, almost at noon, and for that reason, I suppose, no details of it are given in the *Nautical Almanac*; but to those who take pleasure in daylight observations this occultation will be both instructive and interesting. At the time of its occurrence the moon will be twenty-five days old, a small waning crescent, but still distinctly visible in the field of any common telescope, and Aldebaran will also be plainly perceived by the same means before disappearing behind the moon's bright limb. The immersion takes place on July 8, at 23h. 23m. 26s. astronomical reckoning; in other words, on July 9, at 23m. 26s. past 11 o'clock in the morning civil time. The emersion takes place in the afternoon at 15m. 16s. past noon. The Angle from Vertex at immersion is 83deg., and at emersion 351deg., reckoned towards the right hand in an inverting telescope: and the least distance of the centres is 10·5′. Such are the details of the phenomenon, and if the weather be favourable the observation will afford as much pleasure as any occultation observed at night. The moon will be declining towards the west at an hour angle of 2h. 4m. at immersion, and of 2h. 56m. at emersion. The occultation of Aug. 5, may give pleasure in other climes in the opposite hemisphere, but not in ours. In September, however, fresh opportunities are afforded. That which occurs on Sept. 1 is described at length in the *Nautical Almanac*, although the immersion alone is visible, and that, too, at the untimely hour of 20 minutes before 2 o'clock in the morning. There is another occultation, however, on Sept. 29, which deserves, I think, some recognition in our national ephemeris, even though it also takes place in the daytime, and so I will proceed to give some particulars of it. At the time of immersion—viz., 33min. 9sec. past 8 o'clock on the morning of that day, the moon will be declining towards the west at an hour-angle of 4h. 37m., her age being 20 days, or six days past full. The emersion takes place at 19m. 54s. past nine the same morning, the least distance of the centres being 10·0′. The angle from the vertex at immersion will be 175°, and at emersion 273°, the angles being reckoned as before. October brings no favourable occultation, but on Nov. 22, at 9h. 48m., the star will immerge behind the moon, reappearing again at 10h. 57m. This is the last of the season, and is described in the *Almanac*; but what I wish to observe is, that as far as amateur astonomers are concerned, the *daylight occultations* of July 8 and Sept. 29 are quite equal in interest and importance, and are quite as favourably circumstanced for observation as those of which the particulars have been more fully calculated by others, as I have done these for Greenwich.

**James Pearson, M.A., F.R.A.S.**

Fleetwood, March 9.

## THE NEW TIME.

[23961.]—I cannot agree with Mr. Hopkins, p. 36, that it is a matter of "considerable uncertainty" whether or not the "new time" will ever become part and parcel of our everyday life. It is a long fly from here to "ever"; but at present I have not been able to discover a single valid reason why the change should be introduced, though I can quite understand that for records of meteorological and astronomical observations, including time-tables and the *Nautical Almanac*, there is an obvious advantage in using a day of twenty-four hours. It is not easy to make a change, but before the public is asked to talk about "Come to dinner at 18 sharp," I think the astronomers might be requested to use at least a natural day, and commence a new one at midnight instead of noon. That may be advisable, but I think it is tolerably certain that the public generally will still divide the day into two halves of 12 hours each. In what way would railway time-tables be "less liable to confuse" if the abbreviations a.m. and p.m. were rendered unnecessary? The "masses" do not consult time-tables, and what sort of people are they who are "confused" now. On p. 367 of the last volume I asked "Is there any hour in the whole round at which a mistake could be made" in connection with the ordinary purposes of life? and I am still waiting for an answer. I suppose Mr. Hopkins did not see Sir E. Beckett's letter in the *Times* of Feb. 2nd, and I will, therefore, ask you to preserve some portions of it in these columns for the benefit of those who still appear to think that every change is an improvement. Says Sir Edmund: "I have asked everybody who has proposed such scheme to me what he thinks will be the good of it. I have never yet got anything in the shape of a practical answer except that it 'will save so much trouble and prevent so many mistakes in doing Bradshaw.' Will it? I answer. Have you ever considered whether four figures in a Bradshaw column, such as 12.45 (which is the way they are printed) are nicer to read and less liable to mistakes than 2.45 or a space equivalent to the spot, which would become 14.45? To that I have never got an affirmative reply, and of course not to the further question whether they have considered how many more figures the whole of Bradshaw will have to hold when all the most working hours of the day—i.e., from 1 till 9 p.m., will want four figures instead of three. There is practically no confusion between the "mrn." and "aft." of Bradshaw, and they occupy no space that could be saved or used otherwise. I have been looking for a page in which one could make a mistake without gross carelessness, and I cannot find one, though I do not profess to have examined every one. It occurs to me, however, that time-tables might well adopt 0 instead of 12 for either noon or midnight, by agreement, which would catch the eye still more.

"It is, no doubt a curable difficulty by Act of Parliament, like the permissive use of that French blunder which Sir J. Herschel always wrote against, the metric system, founded moreover on a wrong measure of the earth's axis, but there is no such legal time in England at present as anything beyond 12 o'clock. Scientific men may indulge in the affectation of millimètres and kilomètres and kilogrammes, and imagine that anybody realises those fantastic designations of lengths and weights except themselves, if they do. But we cannot have two kinds of time going at the same time. And so for the purpose of considering practical results we must take it that all public and most private clocks are to be reconstructed to show and to sound up to 24 o'clock! Have people considered what that means?"

After some remarks about the striking of the hours and the pointing of the divisions on the dials, Sir Edmund proceeds:—

"And what is the basis of all this nonsense? Simply the priggish notion that it is the scientific and correct thing to do, whether anybody wants it or not; and that it is going to be the fashion and therefore we must adopt it at once. Who does want it? The paragraphs sent to you and other newspapers go on asserting the absolute fiction that the astronomers at the 'Prime Meridian Conference' want it. If they did it would not signify a farthing unless they could show us what real good it is to do. But they never said a word of the kind. It is true that our new astronomer at Greenwich wrote something about 'the public meeting him half-way' when he set back Sir G. Airy's Greenwich gate 24-hour clock, which astronomers always note their observations by, to its new zero at midnight of last 31st of December instead of noon on the 1st of January. But what reason is that for our reconstructing all our clocks and half of our language about time? The celestials altered their zero for their own convenience and good reasons. Twenty-four hours still suit them best, only with our zero instead of their old one. Twelve suit us terrestrials best for a multitude of reasons; and for once the reasons are absolutely all one way, which seldom happens. And one alteration is greater infinitely than the other. Noon is in itself a substantial and real physical epoch for reckoning our hours from, though it is not so good a one as the dead interval between two working days to reckon days from. It is altogether a confusion of those two ideas to have a time running through the great epoch of the day and treating it like any of the more arbitrary divisions, such as 11 or 1 o'clock."

"The watchmakers are bewildered to know whether they should put their XXIV. at the handle, or 'pendant' (as we call it at the Horological Institute) or leave the XII. there and turn the XXIV. upside down. I can only give the well-known answer, 'which you please, my little dear;' there is no wrong nor right in such a matter, except that either is absurd and wrong, and will never be got into use. People talk boldly and largely about some other countries using it. But I also hear that they do not really use it. Not that I care if they do. That does not make it a bit more convenient than it is. That will not make 300 strokes a day of Big Ben or the clocks on our stairs as easy to strike or to count as 156; nor enable any human being to tell what o'clock it is by a mere glance at the position of the hands; nor any human mind to realise as rapidly the effect of 20 o'clock as of 8 o'clock; nor do any single thing for us that the old reckoning and the old machinery does not do better."

I think there is one addition needed—the watchmakers are no longer "bewildered"; those firms who went in for 24-hour watches find that after the first "rush" they don't sell at all, and look much like becoming dead stock; but, now, after all this, I hope if any one has a word to say in favour of the change, he will give some reason for it, and not deal in vague notions that it would prove a great advantage, and be a more "scientific method of dividing the day."

**Nun. Dor.**

## HINTS ON MAKING COLD CHISELS.

[23962.]—Of all the quackery in the workshop there is none to compare with the so-called "secrets" of hardening and tempering. Many smiths have a secret welding powder, the composition of which they would not disclose for less than a fortune; but welding fluxes are not in it with solutions for hardening. It is annoying, though, when somebody rather more intelligent than the average mystery-holder comes along and hardens a chisel or what-not in plain water just as well as can be done by the man with the "secret"—the possession of which has given him all the pre-eminence he is entitled to hold in the shop. The following remarks I saw recently in an American paper, and they appeared to me to be so much to the purpose, that I cut them out and posted them up in our shop for the benefit of all who would care to read. I send them to you in order that they may be criticised by those who are competent for the task. The writer says:—"I have seen smiths heat a drill or chisel for about ⅝in., and then strike 300lb. blows to draw the steel, just back of the hot place. It causes terrible strains in the chisel, and if a fire crack comes in and about half the width of the chisel breaks off, they pitch it into the scrap heap, or tail-race, and cuss the man that made 'that poor steel.' Everybody writes in the papers against heating steel too hot, or 'burning it,' but half the trouble with cold chisels is caused by too little heat. Heat steel as hot as it will bear, and work it while hot. If you wish to work ¾in. of the end of a chisel, do the heating back of where you intend to hammer. Heat 1¼in. of the tool. It takes a trifle longer, but you can work it much better. It will hold the heat and work easy. Don't try to temper a chisel with the remains of the forging heat. Use a fresh heat for tempering, and heat enough to harden. Leave all tempering 'medicines' for somebody else; if you cannot get a temper with good fire and water, you have mistaken your vocation, and had better try some other track. When tempering cold chisels, or any other steel articles, heat to a very dull red and rub with a piece of hard soap, then finish heating, and harden in clear, cool water. The soap prevents the oxygen of the atmosphere from uniting with the steel and forming rust or black oxide of iron. The article will need no polishing to enable the colours to be seen. Never 'upset' a cold chisel. It is sure death to the steel. Make chisels short for hard, rough work. They transmit the power or force of a blow much better. Long chisels are apt to 'broom up' on the hammer end, as the long steel through which the blow passes has more chance to absorb the force of the blow. The harder the metal to be worked, the quicker the blow should be transmitted. Cast iron works much better with a short steel chisel and light hammer than if the blow was struck upon a very long chisel with a heavy wooden mallet. In one case the blow is delivered 'all at once,' in the other it takes time, and much of the force is absorbed.

"If the head of a chisel 'brooms up,' don't forge it into shape again, but grind off the steel that curls over. Never harden the hammer end of a chisel. It is a nasty trick. The first thing you know a piece of steel will fly and strike your hand. It will cut where it hits, no matter whether it strikes hand, face, or eye. Keep the chisels nicely ground. One end needs grinding as much as the other.

"We cannot tell what 'colour to draw to' when tempering. We don't know, neither does anybody else, until he has worked the steel. If it works easy and appears rather soft, it is safe to assume that it will stand a harder temper than if it took two blows of the hammer to make one dent. I have used the hot sand bath and melted lead for drawing temper, but I must acknowledge that I like an open charcoal fire the best. Hold the article high up over the fire—just above the flame is the best place. Keep it in motion, turning over and over, and never hold still in one place. Let the temper down slowly. If a chisel, you can get ½in. of the point down to colour. If you run it down quick, the extreme point only will possess the right temper, and if it gets broken off a little it will be too soft after grinding out. Taps, tempered slowly, work much better than those which are drawn upon the jump."

**Essar.**

## THE MUSICAL SCALE.—TO S. E. HUNT.

[23963.]—The point in dispute between Mr. Child and myself is not quite as you put it in your letter on page 11. I do not suppose that I "create" a scale; but that, having certain tones and semitones, I arrange them in different ways, and call each variation the scale of such and such a keynote. It is just as if we arranged a number of colours in stripes: we may consider each particular arrangement of the order of the colours as a different pattern, and name the pattern from the particular colour that we make our first stripe. I, in common with, I suppose, 999 out of every thousand musicians, refer to and treat each pattern as distinct in itself, while Mr. Child prefers to call them "modifications." Of course, he is at liberty to do so; but it certainly savours considerably of impertinence when he declares that all those who differ from him and prefer the ordinary nomenclature are "misled," and so forth.

As regards the relationship of the tones to one another, your table of intervals is just what I wanted. I have now obtained the intermediate ordinates of the curve referred to in my former letter (the lengths of the octaves being taken as the primary ordinates), and have placed the results side by side with your own. A comparison between the figures is interesting, as showing to what extent the ratios, as determined by the musical ear, differ from the regular progression given by the mathematically-determined curve.

I have not made a distinction between D sharp and E flat, nor between A sharp and B flat; but if I had done so, there would probably have been a closer agreement between our figures at those points of the scale. I should perhaps add a line to inform Mr. Child that his recommendation to make some organ pipes comes a good many years too late; that my opinion "now" is just the same as it has been throughout the controversy, and that the information which he was unable to supply was quite clearly asked for at the time.

## HOW TO MAKE A SQUARE.

[23964.]—The following is at once so amusing, and so much to the purpose, that I venture to ask you to print it for the benefit, not only of apprentices, but also for the instruction of some of your older readers. It is from the pen of Mr. J. F. Hobart, and I found it in the *American Machinist*:—

"Tom has been promoted. He learned to chip castings and hammer his thumb. He did his first piece of 'Government work' by making himself a hammer, and now he has just spoiled his first iron with the bolt cutter, and his entire mind is bent upon making a square, while the background of the future is lined with visions of calipers, straight-edges and a surface gauge. Tom has got a piece of steel all ready, he has annealed it very soft, and is aching to begin his square. When he gets a chance, he marks out a square and begins to chip it out with a cold chisel. It was slow work. 'Guess I'll drill a hole in the corner,' said Tom. A good idea: it worked so well that Tom kept drilling holes until the whole square was cut out.

"What a time Tom had with that tool. He planed it all nice and smooth, rubbed it with file and emery paper, and wished he had a steel stamp to mark his name on it with. The first time Tom got a chance, he tried his square on old Tim's. What was the matter? Tom's square did not fit. It was open at the toe of the tongue when tried inside Tim's square, and 'wasn't anywhere' when tried outside. Poor Tom. He stuck that square in his breeches pocket, sneaked back to the bolt cutter, and kept thinking the rest of that day. Tom worked all his spare time on that square for the next two weeks. He filed, draw-filed and emery-papered until he was sick of it, and sick of squares too. It was awful work. Got the tongue so it would reverse on a line drawn across the planer bed, and Tom found the blade to be just a little 'hollow,' and by the time he got the blade in shape again, then the tongue was 'out.' Tom worked at the thing until the tongue got too narrow, and then he laid it up with his first hammer, which had a circle of fire cracks around its edge. Tom was bound to have a square. He intended to have a good one, too. He tried it again, and got three pieces of steel ¼in. thick, and big enough for blade and tongue. The two pieces for the blade Tom planed, filed and scraped. The blade to this square was to be thicker than the tongue, and was made in two pieces, riveted together, and Tom worked them out the same width. He got the surface plate and made one edge of each piece fit thereon. He didn't trust file and emery this time, not a bit; he got a scraper and did his best to make twins of those two pieces of steel. They were tried together on the plate until they would stand up square, close together, until they were just of a width and could be changed end for end, bottom side up or laid down flat-wise without showing an error.

"When Tom had done his best with the blade, he scraped the tongue true upon its flat sides, filed out the blade half the thickness of the tongue from each half, and scraped them to a fit. He kept trying together on the surface plate, and made the tongue stand true flat-wise. He fitted it so that it was a little less than 90° with the blade; then he was sure that no scraping must be done close to the blade, but whatever the error might be, it could be corrected at the toe of the tongue. Tom didn't try to make the tongue as he did the blade, that is, parallel edges, and fitted into the blade just 90°, or "square." He learned better than that when making his first square. After drilling the holes, reaming them, and riveting all together, being very careful not to 'cripple' a rivet, or spring the blade out of true, Tom was ready to true up the tongue with the knowledge that the blade was *right*, and nothing need be done to it.

"Our Tom has arrived at the dignity of running the 'Fitchburg Lathe.' He puts a piece of iron cut from a 4in. shaft, between the centres, and turns it as true as he knows how. He does his best to make both ends of that piece of iron the same size. When he can't make it any better, Tom cups out one end of the iron, leaving $\frac{1}{16}$in. around the outside, cutting the centre back so the iron will stand true on that head. Tom stands it on the surface plate and scrapes the outside of his square tongue until it is a fit. He tries that square all around that piece of iron, and cannot find a single place where it is 'out.' To true the inside of the tongue, Tom worked with the calipers, testing for straightness on the surface plate, and trying the square on the turned iron, letting the blade extend across the end, or cupped portion, and fitting the tongue to the side. When that square was done, Tom could draw a line across a straight edge, turn the square over, and draw again; draw two more lines along inside of the blade, and leave but a single line across the straight edge. It was a good square; Tom was proud of it, and everybody knew it, too. But Tom says the next time he wants a square, he will go to the store and buy one of Stubbs', or Brown and Sharpe's. If anybody catches him again working 82 hours on a square which he could buy for 2.50 dols., then he hopes to be a candidate for a lunatic asylum, or a job in the navy yard." **Economy.**

## A NEW AMERICAN LOCOMOTIVE.

[23965.]—The following particulars of a new design in American locomotives will, no doubt, interest some of your readers. It is known as the Cooke 10-wheeler, and is one of seven recently built by the Cooke Locomotive and Machine Company, Paterson, N.J., for the Elmira, Cortlandt, and Northern Railway. The most prominent peculiarity about the engine is that a four-wheel engine truck is placed entirely in front of the cylinders. This is, however, not the only point in which the design departs from the ordinary accepted American practice. The boiler, which is of the waggon-top type, has the cylinder part 54, tapering to 55¾ inches diameter, and is intended to carry a working pressure of 175lb. to the square inch. To sustain this extremely high tension the boiler shell is made of steel $\frac{7}{16}$in. thick. The longitudinal seams have welts on the inside, with rivets alternately on each side of main seam to strengthen caulking edge. There are 200 tubes, 2in. diameter and 10ft. 8in. long, fastened with copper ferrules at both ends, and brazed to flue on the fire-box end. The fire-box, which is made of the best Otis steel, is 73in. deep, 72in. long, 33½in. wide, and has a water space of 3½in. between the sheets. This boiler supplies steam to cylinders, 20 × 24in., which transmit the power to three pairs of coupled driving wheels, with 54in. centres. The valves are the Richardson balanced; pistons, cast-iron, corrugated shape, with three cast-iron packing rings ½in. square section. The boiler is covered with asbestos lagging; two sand-boxes are placed on top of boiler; an extended smoke-box and open stack are used. The engine is fitted with the Eames brake equipment, and the shoes are applied to both sides of the driving wheels. No pumps are used, the boiler feeing being done by two Hancock inspirators, one on each side. **E. A. M.**

## A FEW NOTES ON THE LEICESTER AND SWANNINGTON RAILWAY.

[23966.]—The recent correspondence relating to early locomotives has directed attention to this line, some notes upon which may therefore prove of interest to your readers.

The Leicester and Swannington Railway is one of the most ancient and most interesting lines in the kingdom, but probably the least known; in one respect it is perfectly unique—namely, that whereas all the other early railways have been very greatly improved, and the systems of working entirely modified, a considerable portion of the Leicester and Swannington line remains, and is worked to-day, upon the old style, adopted nearly fifty years ago; on this account it is frequently visited by engineers who desire to see links in railway history. The Company's Act received the Royal Assent 29th May, 1830, giving power to construct a railway from the navigable part of the River Soar, near West Bridge, Leicester, to the northward end of the village of Swannington, together with four branches, extending to the Whitwick, Ibstock, and Bagworth collieries, and from the ancient Fosse-road to the North Bridge, Leicester. The three former branches were constructed at the expense of the colliery owners; the latter, to the North Bridge, was never made. The line was commenced towards the close of the year 1830, and opened, amid great rejoicings, on the 17th July, 1832. It was the first railway in the midland counties, and, as it follows the short line from Canterbury to Whitstable, is believed to be the second south of Manchester. It now forms the oldest portion of the Midland Railway (the above remarks, of course, refer to locomotive railways, and do not include old tram-roads worked by horses).

From the commencement of the line and the completion of the board-room, until the year 1869, the whole of the official documents remained at the West Bridge station, Leicester; but at that date they were all removed, a few to Derby; but a very large proportion of these interesting papers were destroyed and sent to the papermaker, therefore much information relating to the line has been lost. The writer, for a number of years, took great interest in the history of this railway, and had fortunately taken copies of the sections and all the more important documents some years previously to their being destroyed. This fact being known to his engineering friends, he was specially asked to prepare and read a paper upon the subject. The early letters which passed between Mr. William Stenson, Mr. John Ellis, and Mr. George Stephenson, conclusively prove that the object of this railway was to supply Leicester with coal from the Leicestershire collieries. At the time Derbyshire coal was sent by canal, and the Leicestershire coal practically shut out of its own market. Mr. Stenson wrote: "Our carting beats us, but I see a way to relief if we can but get a railway. I've tried the ground with my theodolite, and find no difficulty."

Mr. Ellis and Mr. Stephenson went over the route, and the company was formed, a large portion of the capital having been raised in Liverpool, Mr. Robert Stephenson, at the age of 27, being appointed engineer. The length of the line (exclusive of branches) was 16 miles 5 chains, or 28,270 yards; it was single throughout, except at stations; the gradients were severe, but that was of little importance, as in a great measure they were favourable to the loaded coal trains. Leaving the West Bridge Station, Leicester, the railway runs past Glenfield, Ratby, Desford, Merrylees, Thornton, Bagworth, to the summit, the gradients being 1 in 147; level: 754, 480, 364, 211, 138, 119, 29, 97; thus, in a distance of 11 miles 30 chains, the line rose to a height of not less than 371ft. above Leicester, from this point it declined by gradients of 1 in 203-251, and 17 past Bardon-hill, the junction of the Whitwick branch, Snibston Colliery, and Swannington incline, to the level portion at the end of the line at Swannington.

The principal work on the line is the Glenfield Tunnel, about a mile and a half from Leicester. It is one mile one chain long, straight and level, built of brick. 500 yards of its course lay through loose running sand, the presence of which rendered it necessary to construct a wooden tunnel to support the soil while the brickwork was being executed; the construction of this tunnel was carried on from both ends, and from four large and ten small shafts. A serious mistake was made, either in the level of the rails or height of the engine chimney, for on the opening day the chimney of the engine drawing the first train was knocked down.

The gauge of the line was 4ft. 8½in., the rails being of the "fish-belly" pattern, weighing 28lb. per yard (for full details of the permanent way, reference should be made to Vol. XXXIX. p. 589).

The Bagworth incline was self-acting: the loaded waggons descending (by gravity) pulled up the empty ones by means of a rope, 1,000 yards in length, passing round a wheel fixed at the top. The Swannington incline was, and still is, worked by a stationary engine and rope. Some of the clauses in the early Acts are interesting, for instance, that of

1830 enacts: "That all persons shall have free liberty to use, with horses, cattle, and carriages, the said railway upon payment of tolls." Two lists of tolls are given, one if "propelled and provided at expense of the company," the other not by the company. These powers do not appear to have ever been exercised, and on the 10th June, 1883, another Act was passed, and states that: "Whereas the main line hath been constructed with a view to locomotive steam engines being used, it might be very injurious to the said railway, and inconvenient and dangerous if horses or cattle were used." They were, therefore, disallowed. The Act also gave power to construct a branch to Soar-lane, Leicester; this branch crosses the canal by a curious drawbridge, designed by Mr. Robert Stephenson, and still in use, the movable part being raised and lowered by means of chains at the four corners passing over pulleys and attached to counterweights. Branches were also made by private owners to the Groby granite quarries and to the Snibston No. 2 colliery.

By another Act of 1833, the Coleorton Railway Company made a railway from Swannington to join the ancient Ashby tram-road.

The Leicester and Swannington Railway was purchased by the Midland 27th July, 1846. An Act, 3rd August, 1846, was passed to alter and improve it; this was in the following year abandoned, and another Act passed 2nd July, 1847, by which the present Leicester and Burton line was made; also a deviation to avoid the Bagworth incline of 1 in 29. Six miles near Leicester, and 1¼ near Swannington remain unaltered, and are now practically as they were at first. The trains in 1832 consisted of coal and goods waggons, with passenger carriages attached, and so they do in 1885.

**Clement E. Stretton.**

### THE ACCIDENT AT ST. PAUL'S-ROAD JUNCTION.

[23967.]—I HAVE waited to see whether any of your readers besides Mr. Stretton would notice this question, and I now write to thank that gentleman for his letter on p. 519 last volume, giving the substance of Major Marindin's report on the collision above-named. With regard to Mr. Stretton's last sentence, I would ask, How can the public expect railway companies to take much notice of the reports and recommendations of the Board of Trade officials, when one of those highly-paid (£1,000 a year) gentlemen actually "passed" this very "junction," where it is clear to anyone that the down line from King's Cross ought to have been carried under the main up-line right away clear outside of Kentish Town Station? The direct cause of the accident was not the "combination" of the four reasons named, because, if the gas-pipes had been properly laid and fitted, the other three "reasons" would not have occurred. The direct cause of the accident was, then, the fact that the Midland Railway Company employs officials who cannot so lay gas-pipes as to prevent an accumulation of water, or who have never heard of means for drawing off water without stopping the supply of gas. It is also stated that "the position of the junction prevented the two drivers seeing the danger," a sentence that requires some explanation, for the driver of the down train would see just beyond the signal at the crossing the black darkness of the tunnel under Camden-square. I presume he thought the advancing lights belonged to a train going to King's Cross, while the driver of the main up might have thought the other was waiting for him at the signal-post, as frequently happens. If the gas-pipes had not been stopped by water, it seems clear that this collision would not have occurred. I cannot, therefore, agree with Mr. Stretton, that it was the result of a series of defects and errors of judgment, which were not of a character to necessitate any other verdict than "accidental." On the contrary, the collision could not have occurred except by negligence of the company's servants, or through defects in the arrangements for which the company is clearly responsible. As it happened, only a poor fireman was killed, and the company will not have to pay damages; but life was doubtless as dear to him as to any of us, and he and his fellows are exposed to quite enough risk, without having to run the gauntlet of such traps and snares as this junction has proved itself to possess. Of course a coroner's jury brought in a verdict of "accidental" death—just as they do when boilers explode because they are utterly unfit for the work they are put to do; but no one expects wisdom from them. "Accidental," as applied to railway disasters, means something that "could not have been foreseen," not merely something that "was not foreseen." I quite agree with Mr. Stretton as to the signal lights. I would suggest the use of blue or yellow for distant signals, or what would perhaps be better, red, with a broad bar of yellow across it.

**Nun. Dor.**

### EARLY CUT-OFF ENGINES.

[23968.]—THERE have been several letters lately in your paper respecting the advantages to be gained by the early cut-off engines. My own practical experience is that it is a fallacy; it has failed with me both in practice and in my own theory.

Some years ago I reproached one of my engine drivers for working his boilers at 50lb. pressure, instead of 65lb. pressure (these were a pair of simple condensing engines, with automatic cut-off). He informed me he could work with less fuel at 50lb. than he could at 65lb.; I, therefore, allowed him to do so, as he could do the same work with about 20 per cent. less than any other driver for the same load. At another firm I indicated an engine with automatic cut-off (single non-condensing). This engine cut-off at about one-tenth of stroke, the expansion line passing the atmospheric line at about six-tenths of stroke, the terminal pressure, of course, being below atmospheric line. I advised the firm to run the engines slower by altering the pulleys. This was done, and a saving effected in fuel of about one-third—60lb. pressure was carried on the boilers. Another firm had a patent automatic variable expansion engine, "horizontal, non-condensing," fitted with patent gear of every description: this engine consumed over four tons per week. This firm then fixed their old engine to be worked in case this patent machine required repairing at any time; this engine was a single horizontal non-condensing, with expansion plates on back of main valve, cutting off at four-tenths of stroke, 60lb. boiler pressure. The patent early cut-off engine being stopped for repairs, the old engine was, of course, started, and to the surprise of the firm, only consumed three tons of fuel per week against the other's four tons for the same work and same number of hours. These practical examples prove that early cut-off is a fallacy.

With simple early cut-off engines, according to the indicator card, they give a good result per pound of fuel used per indicated horse-power per hour; but this is a fallacy, because the method of calculating is incorrect.

With an early cut-off, say, at one-tenth, the full initial pressure is when the crank is at dead centre; and this is calculated the same as though the crank was at half-stroke or most effective and quickest speed. The present method of calculating these engines is, therefore, incorrect.

The speed of piston is variable, and the pressure per tenth of stroke being variable, the old system calculating by the average pressures and by the average speed is useless. For instance, an engine working at 400 piston speed per minute would have at half-stroke a piston speed of 628ft. per minute, when the crank was most effective; but when at one-tenth of stroke the piston speed would be only 172ft. per minute, when the crank was least effective and on its dead centre, the speed of crank-pin being 3·1416 the diameter or half-stroke. For the calculations at one-tenth of stroke, we must deduct something like 50 per cent. as useless effect, the crank being on dead centre.

By this method of calculating, we obtain three times the useful effect at half-stroke to what we do at one-tenth of stroke, theoretically and practically; six times the useful effect transmitted to the machinery (the supply of steam to an engine being intermittent, and not continuous) for the same consumption of steam and fuel.

When the position is at half-stroke, the piston and crank speeds are in unison; consequently, we must make our calculations by the normal, instead of the average, speed and average pressure.

In the compound engines, the steam can be carried to seven-tenths of the stroke, thus giving the greatest amount of pressure when the crank is at full leverage, or most effective.

This method does not apply to direct acting, non-rotative engines, the piston speed being almost constant, and effect constant. Any engineer will know that his engine will not start on dead centre, and that the steam is not so effective as when the crank is at half-stroke.

**Christopher J. Little, M.S.Arts.**

### A QUICK SPARK COIL.

[23969.]—THE following description of a coil I have lately made may be useful to some of "ours," though it is not offered as a specimen coil, as the secondary insulation is probably rather too heavy. This, however, if it has prevented my getting the full length of spark out of the wire used, has diminished the chances of breaking down the insulation from using too great battery power. Core: 12in. by 1¼in. No. 18 iron wire, softened in fire all night, bound with soft cotton tape, half overlap, and paraffined, primary (wound thereon) four rows No. 16 s.c., each row separated from next by layer of paraffined tape, last row finally surfaced with $\frac{1}{16}$in. paraffin over the tape. Over this is wound a layer of paraffined silk ribbon, and then a layer of silk tape half overlap, well paraffined, and with ⅛in. thereof for surface, secondary 3lb. 2oz. No. 35 s.c. wound from end to end, twenty-one rows altogether, narrowing from 9in. to 7in.; ends of secondary cleaned for about 6in., and twisted up with 6in. of No. 26 to attach to terminals, and lessen chances of breaking there. Each layer separated from next by one layer paraffined tape, three-quarter overlap at ends, and just overlapping in centre; last row bound with silk ribbon well paraffined, and coil made cylindrical with paraffin; ends ¾in. mahogany dried and varnished; stand half walnut (ditto), condenser (separate), 81 tinfoils 11in. by 7in., separated by paraffined white blotting-papers 12in. by 9in., five extra top and bottom; break horizontal. Terminals, arrangement, &c., similar to one described in "E.M." for 30th November, 1883. Battery: six small bichromates in series. Result: just 2in. spark, primary shock very strong.

**B. Harcourt.**

### USES OF A COMMON PARAFFIN TAPER.

[23970.]—THE following note, which owes its origin to Dr. B. W. Richardson, may be of use to many of your readers; but they should see that the tapers are really of paraffin:—

"A common white paraffin taper makes, I find, one of the best bougies for exploring the nasal cavity. I use a taper of from one-eighth to one-sixth of an inch in diameter, and about 10in. in length. For mere exploration I round off the end that is to be introduced into the nasal cavity, bend the taper into an easy curve, make it slightly soft by warming it in my hand, and then have it ready for use. The perfect smoothness of the surface of the bougie thus formed, the ease with which it bends, and the just sufficient strength given to it by the wick, are qualities which make this simple, inexpensive, and always ready instrument very effective. From its colour it is also readily discernible in the throat when it is passed into the pharynx.

"The taper has other uses. If it be wished to apply iodine evenly to the whole of the nasal cavity, the thing can be done at once by means of the taper. It is merely necessary to paint the end of the taper for a couple of inches with iodised colloid or with tincture of iodine, and then introduce it, to secure that all the iodine is left on the mucous lining of the nasal cavity. In ozena, patients can be taught to carry out this method for themselves at stated times. I have two patients now who have done this with the best effect.

"The taper admits of another useful application. If the cotton within it be nicely teased out at one end of a short length, the cotton makes one of the most convenient of brushes for applying iodine or other solutions to the throat. In scarlet fever and other affections attended with throat complication, I invariably instruct the nurse or attendant to be provided with a few tapers of different sizes, and to make them act as the brush for applications to the throat; and as soon as one brush has been used, to cut it off with scissors, burn it, and make another. The same kind of brush can be used with equal advantage for cleaning the tube after the operation of tracheotomy."

**S. R.**

### COMPOSITE PORTRAITS.

[23971.]—I DO not know whether any of our amateur photographic friends have tried their hands at composite portraits—e.g., amongst their own relatives; but they will, perhaps, be interested in reading the following notes on composite photographs of groups of members of the American Academy of Sciences, which was read by Prof. R. Pumpelly. The pictures are obtained, it will be remembered, by taking the photographs of a number of different individuals of the type to be compared, in as nearly as possible the same position. These pictures are then photographed on the same negative, being superposed one on the other, and each photograph being exposed for only a very short time, so that the resultant contains and combines all the features which the different photographs possess in common, but eliminates those which are due solely to individual peculiarities. The pictures are focussed on the eyes; and since the distance in eye differs in different persons, some indistinctness about the borders of the picture is inevitable. The mouth especially appears to lack decision, by reason of being somewhat blurred; yet, on the whole, the composite picture is such a one as would be at once recognised by most persons as a fair illustration of such a kind of person as the individuals which compose the class under observation. It is by somewhat such a process as this, in fact, that Prof. Pumpelly thinks that we usually form a mental image of different types and classes, whereby we recognise, for instance, at sight a Chinaman or an Indian. The pictures of members of the Academy showed in one instance a compound formed from thirty-one individual members. This picture may fairly be taken as a type-picture of the average scientist or the ideal intellectual man of the Caucasian type, being composed as it is of individuals the most eminent in America in various lines of scientific research. It shows, as must have been expected, a high and massive forehead, and that well known though indescribable cast of countenance which we all pronounce at once, without perhaps being able to assign any reason for it, to be intellectual, so that on seeing a countenance of this stamp we naturally infer that it is that of a professional man. It was observed, however, that the faces of three of the persons thus combined differed largely from thé average type, and in the subsequent experiments these three photographs were omitted for the purpose of securing greater clearness in the result, notwithstanding that the exposure of each picture to the camera was only two seconds, out of the total exposure of sixty-two seconds for all, so that the peculiarities of individual pictures would make only a very feeble impression on the combined photograph. The remaining twenty-eight pictures, then, were divided into two groups, and classified, according to the department of science most affected by the members, into sixteen naturalists and twelve mathematicians. On combining the mathematicians into one group and the naturalists into another, it was seen that, with apparently the same height of forehead, the mathematicians have a broader, and the naturalists a slightly narrower, forehead than the average. Prof. Pumpelly intimated that it was his intention to prosecute these inquiries in the direction of composite profiles, which he expected would produce some startling results. He regarded this as a method of much value in anthropological work. Major Powell stated that the same method had been applied to obtain a composite photograph of crania at Washington, but without success. Other members of the academy, however, indorsed Prof. Pumpelly's views. Prof. Peirce thought it particularly desirable to obtain a composite photograph of musicians, and also of mathematicians who were devoted exclusively to mathematics, remarking that the members of the academy represented were not of that exclusive mathematical type which he regarded as a very peculiar one.

Newport, R.I. **R. Scanlan.**

### THE STATE OF MAN.

[23972.]—I observe that objections similar to my own have been taken to "Priam's" statement that Moses was unaware of the legend of the Six Days' Creation. "J. H." meets me as I have hoped some able critic would do; but there is still a sticking-point.

In personally endeavouring to solve the difficulty which, be it observed, is one which a parson has to meet, I have stated it thus: "In the beginning God created heaven and earth." This I have supposed to stand as a positive incontrovertible fact, as the necessary foundation of the whole religious system to be presently set forth.

As to date of this fact, it needs none. It may have been millions of ages ago. Then in verse 2 commences the rearrangement or re-creation out of the above chaotic mass, which may have already, however, have seen divers previous restorations and subsequent destructions.

This seems also to be the view of "J. H." I am no Hebrew scholar; but I believe that "The earth *was*" without form, &c., may be read "became" without form, which would go far to substantiate this view.

But to quote from a most interesting volume, "The Conflict of Religion with Science"—"*Since* the advent of man we have to deal "with periods of incalculable length," — i.e., possibly from tertiary, and certainly from quaternary times. But if I understand "J. H." aright, he sets down these as geological periods, comprised in verse 1 of Genesis, and man's existence would thus antedate the six days' re-creation. Bible chronology makes man but 6,000 years old. Scientific discovery gives his existence with certainly hundreds of thousands of years. "It is difficult to assign a shorter date for the last glaciation of Europe than a quarter of a million of years, and *human existence antedates that.*" If Bible chronology is not, as I said, hopelessly at fault, geological chronology is. Commonsense will scarcely ask which is, in such a matter as this, to be trusted. I may observe that I do not consider that Christianity depends upon the Mosaic record of creation, which simply opens up, in my opinion, a field for scientific discussion. At the same time there are manifest reasons why one would be better satisfied if the theological and the scientific record could be reconciled. As to the glaciation which may have wrecked our world, I can understand that the gradual cooling of the materials may have arrived at such an extreme; but how did the revivifying or warming process begin?

Let me hazard another theory. The total glaciation of the globe took place at some remote period antecedent to the six days. Then came the gradual increase of temperature. The mass of ice was dissolved, and hence the universally diffused waters upon which the "Spirit brooded"—that spirit, or breath of God, then causing evaporation to take place, and so by raising the clouds "divided the waters from the waters," which was the first act of the renovation of the earth. Possibly Moses used the term "Spirit of God," for lack of a better, to indicate the revivifying influence of heat. Did glaciation make as positive a break as the above would suggest, or do geological and Mosaic periods merge into each other by imperceptible gradations?

**O. J. L.**

### CUTTING SCREW-THREADS.

[23973.]—Though I am perhaps trespassing a little, not having had such experience of revolving laps as would entitle me to be heard, or of weight in the present contention *re* cutting of screw-threads, &c., I take the liberty to point out further, as one who has been a responsible workman and draughtsman, that Dr. Edmunds is wrong anent the angle of his cutters or laps to make up his thread. If a thread were cut by an inclined lap set to average angle of threads acted upon, the angle in a plane of revolution of axis of screw would be a curved broader-based one, not a duplicate of cutter; in fact, as Mr. Wenham says, the thread would be deformed. The correct form of the lap could be obtained by cutting a thread with a chaser, and turning lap to linear contact for whole depth of thread at either side and at medium angle of thread.

It appears to me, however, that to cut threads with a lap having its axis inclined horizontally, but not vertically, to the screw axis, of small enough diameter to clear, and cutting one side at a time, would be the better plan. I have still a little doubt of the other, double-lap plan; though if wheel were small enough, with a sufficiently obtuse angle on the thread to be cut, sufficient clearness should exist, and the resultant thread of a properly shaped cutter should be correct in form.

Revolving laps are more a workshop than an amateur's—at least, the general amateur's—appliance, and I am confident do not contain the same possibilities of accuracy as bit-laps do, and the final finishing of the lapping should be done with the latter.

Mr. Granger proposes to use an extra and approved non-necessitous centring on the exposed outer end of nose, needlessly increasing complication. Perhaps he has looked up recent letters in the mean time, and found out how his proposal stands. **Vulcan.**

### INTERCHANGEABLE MANDRELS.

[23974.]—I do not wonder at Mr. Hines now asking *when* we may expect the Council of the Amateur Mechanical Society to publish its decision upon the thread-form for ornamental lathe screws and other fine purposes; also upon the details of a standard interchangeable mandrel. I confess that I am now tired of this discussion. I have considered very carefully all the letters that have been sent to me or published in the English Mechanic, and I think that now we ought not to wait longer in the hope of propitiating adverse influences. The vested interests upon this question are very strong. Costly lathes, constructed with screw-threads of 9·45, 13·09, 19·89, 22·12, 25·71, 28·88, 36·10, 39·83, &c., turns per inch, become really valuable milch-cows. But those who desire to purchase "a high-class ornamental lathe without any change" out of a five-hundred-pound note will always find Mr. Evans's factory at their service, and no one wishes to interfere. All we have to do is to sum up the outcome of our work upon this subject, and leave the matter in the hands of intelligent purchasers on the one hand, and, on the other, of manufacturers who are sensible enough to see what their real business interests are.

From the first, Mr. Evans, when still absolutely incredulous as to the practicability of my propositions, placed himself at the disposal of the Council of the Amateur Mechanical Society with a view to assist in the practical work of constructing the model screw-threads and mandrel-heads. I have, therefore, asked Mr. Evans to favour me with the conclusions at which he has arrived after following the discussion out, and after having himself manufactured the first of these model interchangeable mandrels. Mr. Evans writes me as follows:—

"1. I intend for the future to use nothing but aliquot threads throughout my apparatus.

"2. For all fine lathe-threads and other scientific work I shall adopt the Edmunds thread-form, as shown in cross section in the English Mechanic (No. 1040, page 562, Fig. C)—i.e., an angular thread of 50°, truncated so as to make its depth equal to the length of its base.

"3. All my best ornamental lathe mandrel-heads will henceforth be made with their chuck-bearing surfaces to the Edmunds model, screwed at the rate of ten turns per inch. For such lathes the transferability of the chucks will be absolutely perfect, and transfer chucks will no longer be required.

"4. For the cylinder-screws of the shifting headstock, I have adopted the thread of ten turns to the inch and a back circle divided to hundredths of a turn. This will make the shifting headstock useful for measuring certain work when between centres, and will at once give thousandths of an inch.

"I have a beautiful lathe in hand, recently ordered to be made to your pattern mandrel-head, which I will ask you to come and see when finished. Of course, as I have said before, my adopting these standards will not interfere with my making any other thread to suit the fancies of particular purchasers; and, for rougher purposes, I shall use the Whitworth standard bolt-thread of 55°, rounded off one-sixth at top and bottom."

The recent publication, at page 14, of Messrs. Whitworth's letter upon their lathe-nose threads is a valuable contribution. In one respect I must correct its statement, inasmuch as I know of one 3½in. lathe, recently made by Whitworth and Co. for a member of the Amateur Mechanical Society, and that lathe has a 1in. nose with a thread of "about 50°," rounded off one-sixth at top and bottom, but making *seven* turns per inch.

It seems as if Sir Joseph Whitworth had never systematised the threads of his lathe-noses as he did those of our standard bolts. An "average of about 50° angle" for the lathe-nose thread is not a standard that can ever be incorporated with scientific work. But the fact that Sir Joseph has never adopted his standard bolt-thread of 55° for his own lathe-noses is conclusive against our now adopting it for the ornamental lathe. We, therefore, fall back upon the angular thread of 50°, truncated so as to make its depth equal to the length of its base. I have no doubt whatever that this is destined to take permanent place as a thread of really scientific form, easily reproduced with exactitude, and free from all troublesome calculations. It yields out of a given cylindrical shell the greatest resistance to shearing or deforming stress, the largest amount of bearing surface, and a minimum of that wedging action which is the chief factor in the abrasion and deterioration of angular screw-threads.

Our model interchangeable lathe-mandrel will, therefore, have the chuck-bearing surfaces shown long since in the engraving in the Journal of the Amateur Mechanical Society, and twice reproduced in the English Mechanic. For the light 6in. and smaller lathe, the nose will be 1in. in total projection from the mandrel-face, and 1in. in diameter outside the thread. That portion which serves as the cylinder-base will be ·2in. long, and 1·05in. in diameter. The thread 50°, truncated so as to make its depth equal to the length of its base, and at the rate of ten turns per inch. The mandrel-face will be 2in. in the diameter of its bearing zone, and hollowed out inside so as to limit the chuck-bearing to a peripheral zone ·2in. in width; the shoulder to offer a rounded edge, which will adequately protect the edge of the true-face zone. For the heavier scientific lathe, a nose 1·25in. in total length, and 1·25in. in diameter, with its cylinder-base ·25in. long and 1·35in. in diameter, the same thread-form as the inch nose, but at the rate of eight turns per inch.

The question of thread-rates is one which will settle itself. For the scientific traversing lathe there should be six guides having 10, 12, 16, 20, 24, and 36 turns per inch. With the larger lathe an 8-thread guide will be necessary, and either 30 or 42 may be added so as to make up a set of eight guides.

The mandrel is bored throughout to ·4in.; the mandrel-tail is guaged to a diameter of 1in. and is fitted with a nut instead of a plug-screw, so that rods can be passed through from behind without unshipping anything. **James Edmunds.**

Grafton-street, Bond-street.

### LATHE MANDRELS, CHUCKS, &c.

[23975.]—My time is, unfortunately, limited, or I should have replied to Dr. Edmunds' question before; in fact, I had Figs. 1, 2, 3, and 4 drawn on the 28th ult., but have been so driven for time that if this appears in No. 1043 it will be entirely owing to the courtesy of the Editor. In spite of Mr. Hines's letter, p. 520, I am still not convinced of the great superiority of the cylinder and face fitting for interchangeable chucks and mandrels over the cone system. He says that the wear on the front portion of a *long* cylinder, combined with the wear upon the chuck, would be sufficient after a time to render its centrality imperfect; but upon Dr. E.'s *short* but enlarged cylinder base there would be no real wear. I submit that if the wear on the long cylinder fit is increased by reason of the extra distance the chuck has to pass over such cylinder fit, when screwed home, the surface of the cylinder which has to withstand this wear, is increased in area in like proportion; but the amount of force with which the chuck comes in contact with the cylinder base would not be augmented were the length of the cylinder increased, and it may be taken as constant; and therefore, were the cylinder's length doubled, the increased area would be subjected to only half, whatever that force might be, and if the length were made 1in., the surface would have to withstand only one quarter the force. Does Mr. Hines mean to say that the friction resulting from a pressure of 4lb. on 1 sq. inch would wear away such 1 sq. inch very much slower than if the 4lb. were spread over 4 sq. inches, where the pressure or weight would only equal 1lb.

to each sq. inch? Thus in this latter case a square inch has only to withstand a pressure of ¼ of the 4lb., or 1lb., and the total surface is four times as great. If I am wrong in my reckoning, will he be so kind as to show me where, and in as clear a manner as possible? and the long cylinder affords better opportunities for rounding the entrance of either chuck or mandrel, and the extreme south ½in. of mandrel and the north ½in. of chuck will have no greater distance to travel than in the standard mandrels; and therefore it seems to me that to continually insure the truth of chucks, mandrels should be constructed on one of the following systems—viz.,

System 1.—One cone of suitable taper, supplemented by some means of attachment, which may be a screw of square or angular thread, or bayonet-jointed, &c.

System 2.—One cone and one flat mandrel face.—In this case the cone must either, whilst perfectly fitting the mandrel, be made to slide towards the face, or the cone must take the form of an angular screw thread.

System 3.—*Two or more Cones opposed to each other.*—In which one cone with a plane base may be opposed by the advancing or spiral cone of an angularly-threaded screw, or by a series of such spiral cones provided by several complete turns of such angular threads. On page 431 I asked Dr. Edmunds to show a cause why a chuck fitted to its mandrel by a cone cannot be relied on to keep true, when the cone system answers so perfectly for the wearing parts of the mandrel. He replies by questioning the correctness of my analogy, and points to the "dead" centres as illustrating a means affording the attainment of extreme accuracy in work mounted between them; by which I presume he implies a centre fixed to a revolving mandrel, by cone or otherwise, cannot be so implicitly relied on to run true. If this supposition is correct it will be worth while to investigate the cause of failure on the part of the "live" centre, and we find that the error must exist either in the centre itself or in its attachment to the mandrel, or in the latter, and if it is allowed that the latter does run true in its conical or other bearings, we are reduced to the first two sources of error. Then the question presents itself: Can a centre be truly coned to, say, 50°, and, we will say, truly tapered so as to accurately fit a conical hole in the mandrel nose? If a centre can be so accurately coned to 50° that work revolving on it as a "dead" centre can be most perfectly turned circular, I think it will be a difficult thing for anyone to prove that the tail end of the same centre cannot be as accurately turned to a cone of 10°, or less taper. Since this is so, the conical hole in the mandrel nose is alone left as the source of error when turning between *live* centres. It is presumed, of course, that the work is properly coned out to fit the 50° male centre. Now, can such a hole be made perfectly true with the axis of revolution of the mandrel? I should be surprised to hear that this was an impossibility, and I do not think Mr. Hines would feel inclined to admit he could not accomplish such a task, and I think if he failed to produce such a hole true to within a fraction of the thousandth part of an inch, he would have to admit that his shop "was not on a level with modern improvements in steel work"; but if the mandrel is true, its conical hole with the centre properly fitted therein also running true, and the work properly coned to fit the 50° male centre, there can be no error. Is such truth impossible? If so, we may at once throw the cone system overboard; if not, we can rely to produce with such a fitting as accurate work with a "live" as with a "dead" centre—theoretically, at any rate. Then why can we not equally accurately centre and true chucks, &c., by similar means? Is not a centre, dead or alive, a chuck? And, again I ask, why is the cylinder and face system, which does not afford adjustment for wear, considered better than the cone system which does, and, as sketched in Figs. 1 to 4, gives 6·29 sq. in. of surface to withstand wear, as against 2·3562 sq. in. for the face, and ·6283 sq. in. for the cylinder-fit of Dr. E.'s mandrel? If the conicity were sufficiently obtuse, no doubt the bite of the mandrel-face would interfere with its corrective action; but in Figs. 1 to 4 I have shown that an acute cone may be employed, in which the "north" end of the mandrel does not project beyond its supporting steel collar to a greater extent than in the "standard mandrel" of Dr. Edmunds—viz., 1½in., and here I beg to say that the accompanying drawings are not to be considered as arbitrarily fixing the dimensions, degree of conicity, or precise mode in which the cone system is to be, or can be, adopted; but simply as illustrating the three systems brought forward, and as showing that an acute cone does not necessarily entail a very long mandrel nose.

I hardly think the term "stop-surface" is well chosen for the short cylinder of Dr. E. I think its action is more that of a preventive. On the other hand, the face answers as a corrective should the crank approach it angularly untrue, but directly the chucks are rendered true the corrective action ceases and the stop-action at once comes into play; and if the chuck happens to be a large and heavy one, and the nose thread moderately fine, unless care is exercised, the momentum of the chuck will cause it to be fixed very firmly indeed. The friction on the face and south sides of the screw will then assert itself, and be very manifest when the chuck is removed. Therefore, as this effect closely resembles that in a fly-press, the question of the pitch of the thread might be with advantage entered into. In the fly-press the pitch of the screw is made so quick or great, that on the die coming down the friction is not sufficient to jam the screw tight; but, on the contrary, the handle can be drawn back with but little effort, and yet the pitch of the screw is not so great that the momentum stored up in the mass of metal at the end of the arm tends to shear off the screw-threads rather than cause the die to descend. Cannot a like happy medium be found for mandrel noses? If so, it must, I think, be found possible to do the same for a cone-fitting mandrel nose, provided the angle of such mandrel cone is not so acute that work can be fitted thereto, by a slight blow, so tight that the friction alone is sufficient to hold there, as illustrated by centres so fitted to their mandrels, the taper plug of scroll chuck, &c. That the pressure on the cone fitting is more than on the face fitting, I do not deny; but, as pointed out before, the surface is increased in the former, and I think that if the pressure on the cone was double that on the face fitting of Dr. E., and the surface of the cone also doubled, the pressure on any given area of cone surface would be found to equal that on the face; but this question cannot be gone into until the dimensions of the cone and its angle are given; but if we take an angle of 90° as an instance, and the force with which the chuck is applied to it, as represented by the hypothenuse of a right-angled triangle, the pressure on its mandrel's conical surface will, I think, be found to equal the sum of the other two sides, or, roughly speaking, about $\frac{3}{10}$ more pressure on the sides of the cone than on the flat surface, and the more acute the cone the greater the pressure; still, I am hardly inclined to think this pressure would be so excessive as to prove appreciably detrimental to either mandrel or chuck; but to guard against the possibility of such being the case, there would be no objection to slightly oiling the coned mandrel nose and means of attachment, and then the oil would act as a buffer and lubricant, allowing the surfaces only gradually to come into contract, and then by its greasy nature facilitating the removal of the chuck and prolonging truth of the coned surfaces. With the Editor's kind permission, my illustrations will appear next week.

E. J. S.

## LENS SHUTTERS—ERRATA.

[23976.]—I have not had an opportunity of writing before, or I should have pointed out sooner several very noticeable errors in my letter on "Lens Shutters" (23876, Feb. 27), which I think ought to be corrected, as they would be very misleading to anyone looking through back numbers.

In 5th paragraph, line 3, portion in italics was omitted: "I placed myself *in the scene*, fifty or sixty feet away," &c,

9th paragraph, line 6, should have read: "J aperture. K, thin slip of wood for handle"; and on line 10, "S, piece of string fixed to H and K, measures the distance the slide must be drawn down when exposing."

The letter K on lens-sleeve was not shown at all.

C. R. King.

## OPTICAL ODDS AND ENDS.

[23977.]—I should be glad of any accurate determinations of the amount of light reflected at a perpendicular incidence by glass of various kinds. Professor Tyndall, in his "Notes on Lights," says 1-40th. Another work says 4·25 per cent. Obviously both may be correct, since different kinds of glass may be referred to. A reference to experiments will be acceptable, for I find no account of the means used to measure the percentage.

Secondly, will the loss at second surface be accurately the same percentage as at the first. There is a difference perceptible enough to me in the brilliancy of the reflections from the first and second surfaces, but I do not feel sure this is not wholly accounted for from the necessary loss the second reflection sustains at the first surface and in the substance of the glass. Evidently a less brilliant beam falls on the second surface and again suffers on emergence.

My reason for asking is a wish to work out the loss of light in telescopes. Taking the larger estimate of loss, it follows that in a refracting telescope of two lenses in o g., and two in e.p., and allowing 4 per cent. in each for absorption, only 64 per cent. of incident light reaches the eye.

And now a question as to an eyepiece. In last number of *Observatory* one is mentioned in which, while the power of eyepiece is 327, the power of eye-lens alone is 641. This requires the proportional foci of eye and field lens to be as 1 to 7. Is not this a very unusual proportion for a Huyghenian eyepiece, and is there any advantage in such proportion?

It is generally said that a prism gives more light than a flat in a reflecting telescope; but if the loss of light at the surfaces of a prism is rather over 4 per cent. at each, and then a further loss by absorption in the substance, there can be no gain over a newly-silvered flat, since that returns at least 90 per cent. of incident light. Is it proved that any gain results in light from using a prism? Evidently there is great risk of loss of definition. Those who have used both can tell us whether any faint objects come into view with the prism that are invisible with flat.

Edwin Holmes.

## OPTICS WITH THE LANTERN.

[23978.]—I have observed one or two queries respecting the arrangments for projecting spectra.

I find, after many trials, that it is by far the most convenient plan to place the prism close in front of the objective, the slit being fitted in a frame like that of an ordinary lantern-slide, and placed in the stage.

I fix the prism (of dense flint glass) on a light swinging bracket attached to the hood of the lens, so that it may be readily thrown out of the way when an ordinary slide is to be shown, and replaced at once in its proper position, resting against a stop.

If the prism is of fair size, each face 4cm. or 5cm. square, and if the condenser is properly adjusted, there is little or no loss of light.

Perhaps I may mention a contrivance which I do not happen to have seen on any other lantern—viz., a "double nose-piece," consisting of a strip of wood sliding up and down close in front of the condenser (like an instantaneous shutter), with two circular openings in it, on which are screwed short nozzles, with bayonet joints, for attaching either the ordinary lantern-front, or a polariscope, or a microscope, or a "vertical attachment," or an open platform for fluorescence, and other experiments.

This slider has a spring catch, which arrests it when either of the openings is concentric with the condenser, and I find it a great convenience to be able to use any two of the above accessories without the trouble and risk of unscrewing and changing in the dark, the simple movement of the slider placing either of the two at once in a position for use.

A bi-unial lantern is better, of course; but for scientific purposes the double nose-piece is nearly as good.

E. R. P.

## SOME ARREARS OF REJOINDERS.

[23979.]—Will our able contributor signing himself as "Os" permit me to tell him that I should greatly regret saying anything that might smack of vituperation.

I do not think that any good will result from any further discussion on the gas-engine question, because from facts which should have been discussed dispassionately personalities have crept in. Therefore I, for one, shall at the present say nothing on the subject. I have stated what I honestly believe to be the truth. Others, no doubt, have done the same, and as we cannot agree it is best for us to agree to differ. And, in a spirit *very far* from that apparently actuating one other writer at least, I would say that "R. A." is certainly in error (no doubt unknowingly) when he states what he does on one or two points on page 12.

One is that the cast-iron motor he quotes as Davey's, of Leeds, has nothing at all to do with the one I referred to, so that he has not allowed for the operations of other inventors. As the patent will show, the invention *is not mine*; therefore I speak dispassionately. I think this is at least the second time I have stated I am not the inventor. Yet "R. A." will persist in showering on me honours I do not deserve, or perhaps even desire. I trust this repudiation will at last satisfy him he is endeavouring to clothe me in another man's garments.

"R. A.'s" last two paragraphs are *not* certainly dictated by gentlemanly or professional feeling, and I can only use words similar to those used in a reply I recently had from a very well-known engineer in reference to statements made by apparently interested parties in these pages—viz., that "they were far beneath notice"; and that the attacks of writers from behind the cover of a *nom de plume* simply merited the supreme contempt of silence.

Point No. 2 is that *I am using day by day* gas from the apparatus in question; and that, compared with coal-gas, it does not cost me 9d. a 1,000 cubic feet. If the daily use and cost will not warrant my statement, I do not know what will.

Invicta.

## THE STATE OF MAN.

[23980.]—I DARE say "Priam" will be able to answer for himself; but in reply to "O. J. L.," who asks "If Moses gave Israel the Ten Commandments, whence came the fourth, in which the Creation is so distinctly referred to?" I reply; Few doubt but that Moses gave the bare commandments; but the accompanying explanation in which the Creation is mentioned is doubtful, because there are *two sets* of commandments—one in Exodus xx., the other in Deuteronomy v., each containing explanations respecting the fourth commandment, and both *differing radically*. Now both cannot be Mosaic—neither may be; and there seems less reason to suppose the first to be Mosaic than the second, for the first says the Sabbath was established because God rested on the seventh day—a matter beyond any man's experience; while the second states that it is to be kept because of the deliverance of Israel from Egypt—a thing well in Moses's memory. This point is also dwelt on in Exodous xxv.; while, I think, the six days of Creation are not mentioned elsewhere except in the first chapter of Genesis.

With due deference to Mr. Hampden's authority as a philosopher (letter 23925), I must remark that many persons do dispute, and, in fact, utterly deny, the Mosaic origin of the story of Adam and Eve, though he asserts they cannot do so. Will he kindly give his authority for the statement that good authorities 6,000 years old back up his opinion? Moses lived but 3,459 years ago, and, as I know of no older person claimed to be a writer on these subjects, I am curious to hear who Mr. Hampden refers to.

Why the Mosaic origin of the Pentateuch is doubted may thus be briefly stated:—

1. Because the language used in it is the very same as that used in books known to be later in date; yet the Israelites numbered but 70 souls when they entered Egypt, and can hardly have had a settled language of their own. They were 500 or 250 years, there and left it numbering 3,000,000, having had hard times in working for harsh Egyptian taskmasters—and led by Moses, who was brought up as an Egyptian—yet the language supposed to be used by Moses is found to be the same as that in use long afterwards by cultivated kings and scribes.

Remembering the difference between the English of Chaucer and that of to-day, I fail to see how Moses can have written in the style of David or Ezra.

2. Genesis is clearly made up of several books, written by different people, and joined together by an Editor who clearly lived at a late date. The same editor mentions the death and burial of Moses in Deuteronomy xxxiv., and says, "There arose not a prophet since in Israel like unto Moses." The stories of the Creation and the Flood are told twice, and by different writers, all the parts in which the words "the Lord" occur being written by the Jehovist, and the parts where the words "Almighty God" occur being written by the Elohist.

That these were not the same person is clearly shown by chap. vi. Exodus, where it is stated that God's name of Jehovah was not known to Abraham, Isaac, and Jacob, whereas we find these persons using that name according to the other writer—see Genesis xxvi. 22. Eve uses it when saying, "I have gotten a man from Jehovah," as the word "Lord" ought to be translated.

That the Editor lived long after Moses, one passage alone will show: see Genesis xxxvi. 31, where we read, "These are the Kings that reigned in the land of Edom before there reigned any King over the Children of Israel." That could not be written before the time of the Kings of Israel.

I could give many more texts to prove my assertions; but consider I have stated enough to show that we are not bound to consider that Moses wrote all the Pentateuch, and that he may not have written the stories in question. **Memnon.**

---

[23981.]—IN reply to the very courteous request of "O. J. L." (No. 23923) and others, the authority of the faith that Moses wrote the first five books of the Bible is generally conceded to Archbishop Usher. He was not the first to promulgate this, but he gave his full sanction to it, and the Church accepted the same. Usher also fixed the dates of every event from the Creation to Christ, and for fully two hundred years a gregarious succession of generations, blindly followed the lead of the good prelate, until the modern days of geology, ancient tablets, Darwin, and growing inquiry, compelled the Bible printers to discontinue its chronology.

The strongest proof of the multiple authorship of the Pentateuch, to me, is its own internal evidence, and I suppose even John Hampden would consider as a reasonable doubt the fact that Moses wrote details of his own death. Much interesting light has been cast upon various portions of the Book of Genesis by the labours of Colenso, Dean Stanley, and many of their admirers, in both England and America.

We are taught that man fell, from a state of perfect purity and intellectual supremacy, into the depths of sin and death. We also learn that in his primæval fall he carried down with him the entire unborn human race, not only in its consequences, throughout all time, but on into an endless eternity, and these consequences are so terrible that they are beyond all language to even approach. Now if this momentous fact, the greatest that can occupy the human mind, was familiar to the Israelites, in common with the other writings of Moses, as a truth of eternal import, it is surely fair to expect that some of their prophets would have touched upon a theme so vital. But, no; the incident is never even named, directly or indirectly, between Genesis and Paul. Of course a negative unsupported is not a proof; but J. Donnelly, in his work "Ragnarok," shows that the history of Eden is from the Arabic, and probably even earlier; that the garden was in Ceylon; that the story was very familiar as a legend or ballad, or both, to the founders of Nineveh, as well as to the very early races of the Hindoos, and hence, I assume, it was first taught to the Jews during the Captivity.

Anyone quietly reading the first chapter of Genesis must be struck with the dramatic power, the variety of language, and the true poetry of the author—more in accord with the rapt imagery of the second Isaiah—the prophet who wrote at the time of Cyrus (see Matthew Arnold)—than the crude language of a nomadic race.

At the close of service, if any twenty people were asked why they believed that Moses wrote the Pentateuch, they would probably give an answer about as logical as that of John Hampden in the "E. M." last week: "Of course Moses wrote it." But as Moses himself never laid claim to this honour, nor did any of his immediate friends for him, I claim equal liberty to doubt whether Moses ever troubled himself to write at all. The materials for this occupation in a wilderness are not handy; he had a busy life; he had daily to control, and discipline, and direct, a most turbulent and heterogeneous mass of liberated slaves; and he is much more likely to have himself given the needful laws orally, for others to write out and circulate, than to have devoted much leisure to penning such a massive work as the Pentateuch. The law of the land throughout the Jewish nationality was termed "the law of Moses," and it was often altered and enlarged through the centuries of an advancing civilisation, and was practically lost during the Seventy Years' Captivity. After this a new collation of the sacred writings was made by Ezra the Scribe, for the guidance of the returning and much better educated captives, and this is practically our present version of the Old Testament. All honour to the good, brave man, who, for the service of his God, and the need of his nation, thus patiently built up the most glorious monument the world possesses. Yet in this new dress it is easy to believe that new matter might appear which was unknown to their fathers. The Creation, the Fall, Noah, the true story of whom, or, at any rate, the tablets from which the Jews first read it, are now, thanks to the late Mr. Smith, in our British Museum; Cain and Abel, Babel, and many scraps of ballad poetry of the Tubal Cain age, all appear to have a Post-Captivity, rather than a Mosaic, origin.

It is not easy to explain the addenda to the Fourth Commandment; but it is noticeable that this is the only one in the Ten in which the "motive," without any after-consequences, appears, and it rather suggests a marginal note incorporated. The only chance of proof on this point, that I am aware of, is buried in the archives of Samaria, wherein are preserved many old MS. copies of the Law, some of them claiming to have been written during the reign of David, but which are most jealously guarded from inspection, by the few remaining descendants of the tribe of Reuben.

**Priam.**

---

[23982.]—I DIFFER from "Otter" (23926) in stating that the pages of the "E. M." are unsuited to discussion on subjects similar to the present. Why? Why may not the hardworking English mechanic, such as myself, try to prove that his scientific research and knowledge is in strict harmony with the Scriptures, and also with the higher laws of his being? Surely he ought to be able to hammer out the principles that govern the spiritual part of his nature as well as the scientific and mechanical contrivances, &c., we are interested in. I am sure, from past experience, that our kind Editor will not close the columns of "Ours" from any proper discussion if carried on in courteous language, and if writers will only put arguments and facts, remembering that mere assertion is not argument, nor descending to such remarks as "Priam" indulged in in letter 23902. In desiring to arrive at correct conclusions as to the state of man in his early history, we must understand the meaning and value of "religious truth" and "scientific truth." When these are understood fully we shall find that instead of, as "O. J. L." says, "Scripture chronology being utterly and hopelessly at fault," it is most remarkably and clearly opened out and illustrated by scientific discovery past and present. I would ask "O. J. L." not to assume anything, but to try to prove by proper induction and close examination, because we English mechanics do, of all things, like to have some better data than mere suppositions or assumptions, whether we deal with spiritual or temporal affairs. As you say Scripture chronology is hopelessly at fault, and thus deny the truth of Scripture, I must, to explain my premises, ask "What is religion?" Religion properly defined, is piety towards God. This implies two things, first: a correct knowledge of God, and secondly, the exercise of proper affections in view of that knowledge. The first is theoretic, and is investigated by the understanding. The latter is the practical part of religion, and depends upon the will and moral powers of man. All truth which illustrates the divine character and government is properly denominated religious truth. Now scientific truth is but another name for the laws of nature, and you will find a law of nature is merely the uniform mode in which the Deity works and operates in the created universe. It naturally follows that science is only a history of the divine operations in matter and mind.

I throw aside as worthless the assertion of "Priam," about the Israelites bringing the writings of Moses back from the land of their captivity, merely saying that if they did so it was because they *took* the writings with them to Babylon. I like one of the remarks of "J. H.," "Place God at the helm." Yes, then all will come right eventually, and scientific discovery will ever bear out the ideas of scripture. Scientific method requires, in the language of Joseph Cook, that "when we run up our list of causes, chemical, electrical, physical, mental, spiritual, we should also put on at the top, to reach the infinite, another class, the *unknown*. For even in the 19th century there are more things in heaven and earth than we ever dreamed of in our philosophy." This being conceded, we return for a moment to your idea of Scripture chronology. Now in fixing historical events, several methods have been employed of ascertaining the dates of events. I name four: 1. Observations on generations of men or successions of kings. 2. Celestial appearances and changes, such as (*a*) eclipses; (*b*) precession of equinoxes. 3. Coins, medals, monuments, and inscriptions. 4. The testimony of historians who state the distance between the events or between the event and the epoch. Chronology itself consists of two parts, the first measuring time and adjusting the various divisions, the second fixing the dates of historical events and arranging them in order. Now we come to your remark as to the Mosaic account. That this was written by Moses is capable of undoubted proof. Moses wrote five out of the thirty-nine books of the Old Testament, containing an account of the Creation, origin of primitive nations, of patriarchal history, of the Exodus, the establishment of the Hebrew ecclesiastical economy and their especial history down to the time of his death. These five books contain assertions that he wrote them, and the Jewish nation fully believed in their verity. If, indeed, the Pentateuch was not written by Moses, when could the Hebrews have been persuaded to have received it? The dates given by different writers of the creation of the world are very varied, the generally accepted date being that given by Ussher, which is 4004 B.C. Josephus makes it 4658. There are about 140 different dates assigned to it, some being as low as 3616 B.C., while Dr. Hales gives it as 5411. I must for the present draw my remarks to a close, or I shall exhaust the patience of our Editor, and will only say in conclusion with regard to the early state of man after the fall, that after the sin of our first parents the next transgression recorded as having taken place is that which is generally regarded as of the highest turpitude—murder, and *that* the murder of a *brother!* How clearly this shows that mankind were *not schooled into crime* through successive ages of deterioration! On the contrary, human nature had no sooner become alienated from God by wicked works than it was prepared to plunge into the deepest abyss of moral impurity. As we read on we find this spirit continued to be evidenced with the progressive increase of population until the whole earth was filled with its crimes, the cup brimming full to the period when Divine vengeance was roused, and the Flood was sent to sweep away such a dire epoch. **Arvonia.**

---

[23983.]—YOUR correspondent "J. H.," letter 23927, surely never read the first chapter of Genesis; if he will kindly read it he must see that the light created on the first "day" was daylight. v. 5, "God called the light day, and the darkness He called night: and the evening and the morning were the first day." Now, to the simple unsophisticated mind there is no other explanation than that the first day, i.e., the day defined as the time between morning and evening, the rising and the setting of the sun, were thus created. No amount of sophistry will ever explain what this account of Genesis tells us; that there was evening and morning, day and night, light and alternating darkness, three days "before the sun was created," which, as far as "man" is concerned, produces this very light and darkness, day and night, morning and evening.

The infantile, mythical character of the whole narrative is clearly shown in verse 16, when the sun is made to rule the "day," and the moon to rule the night. The sun "produces" both day and night by its appearance and absence; the moon is as often apparent in the day as in the night, and for a great part of the month invisible altogether; how then can she be said to rule the night, except in poetical fancy? **F. W. H.**

## THE STATE OF MAN.

[23984.]—I AM sure our friend, "A Fellow of the Royal Astronomical Society," would not allow himself to make a misstatement if he knew it; therefore, without allowing any religious considerations or discussion (which I consider totally unsuited to our pages) to enter into my remarks, permit me to concisely analyse the dates of the chronology in Genesis v. and vii. alluded to in his letter 23918.

| | | | |
|---|---|---|---|
| Adam | | | |
| to birth of Seth ...... | 130 | | Adam lived 800 years, and ho was, when Methuselah was born, 687 years old; therefore, Methuselah was 113 years old when Adam died. |
| „ Enos ...... | 105 | | |
| „ Cainan .... | 90 | | |
| „ Mahalaleel. | 70 | | |
| „ Jared .... | 65 | | |
| „ Enoch .... | 162 | | |
| „ Methuselah | 65 | –687 | |
| „ Lamech .. | 187 | | Methuselah, it states, was 969 years, and he died. Therefore, he died in the same year that the flood is stated to have occurred. |
| „ Noah .... | 182 | | |
| „ Shem .... | 500 | | |
| „ The Flood.. | 100 | –969 | |
| | 1656 | | |

Therefore, if we are to suppose the history of the world from the time of Adam to the Flood was traditional, Methuselah could have taken the history from Adam, as they were both alive for a period of 113 years.

The "mythical character" of the early history is therefore consistent in itself, and does not show, as "F.R.A.S." states, "that Methuselah must have survived the Flood." **J. S. B.**

[23985.]—IN letter 23927, page 31, the old theory of a vast interval of time existing between ver. i. and ver. ii. of the first chapter of Genesis, during which period everything shown by geology occurred is revived. Against this idea, which never entered the mind of any student of Genesis until geology forced it there, many arguments may be adduced. The division into verses, it must be remembered, is modern; no such breaks exist in the old Hebrew rolls, and ver. ii. really is quite continuous with ver. i., with which, moreover, it is directly connected by the word *and*, clearly implying immediate succession in point of time. To interpolate countless ages between the two verses is against all rules of interpretation, and is also in direct disaccord with Exodus xx. 2. The phrases used clearly show that the writer of Genesis had no such idea in view. Further, according to ver. xix., the sun was not made until the fourth day; that is, not until after the period to which "J. H." assigns geological time, but plants could not grow nor animals live without the sun. In no merely figurative or poetical sense, but in strict scientific accuracy, every animal or plant owes its life to solar energy. How then could either animal or vegetal life exist on the earth during this interpolated period before the creation of the sun, and how was the earth kept in its orbit during the said period? "J. H." tries to meet the first part of this objection by asserting the existence of light independently of the sun. I am not aware of any such source of light, except such as are contrived by men, and there were no men during this period, and therefore no light, not even starlight, for the stars were made on the same day as the sun. Thus we are asked to believe that all the geological plants and animals lived in darkness, which is absurd. The crowning argument against the theory is, of course, that derived from the work of Darwin, which shows that, instead of having been created perfect, man has really been evolved from the lower animals, being but the highest link in the great chain of organised creatures. **Wm. John Grey, F.C.S.**

Newcastle-on-Tyne.

[23986.]—I SHOULD like to state, purely in the great interests of science, that the British Chronological and Astronomical Association has succeeded beyond the possibility of question in enumerating all the chief total eclipses of the sun and moon, and also in tabulating the transits of Mercury and Venus, thus forming three astronomical lines of time reversed from the present period to year 0. The association also has formed the solar cycle of simple lunar years, which are precisely the motions of the moon and the axial revolutions of the earth. Upon this solar-luni cycle the two astronomical lines of years have been extended, and the result is a correct line of time. It is proved by the fact that an eclipse repeats its date after 651 years, called the great astronomical year, and as the solar cycle shows, occurs on the same day of the week, thus:—

| | | | |
|---|---|---|---|
| Year | 1 | 1st of fourth month, | Friday-Saturday. |
| | 651 | | |
| Year | 652 | do. | do. |
| | 651 | | |
| Year | 1303 | do. | do. |
| | 651 | | |
| Year | 1954 | do. | do. |
| | 651 | | |
| Year | 2605 | do. | do. |
| | 651 | | |
| Year | 3256 | do. | do. |
| | 651 | | |
| Year | 3907 | do. | do. |
| | 651 | | |
| Year | 4558 | do. | do. |
| | 651 | | |
| Year | 5209 | do. | do. |
| | 651 | | |
| Year | 5860 | our 1861, Jan. 11-12th, | Friday-Saturday. |

A natural luni-solar cycle of seven years will produce the days of the week and dates of the month by giving 30 and 29 days alternately to the months.

The point of interest is—and it is a great one—the years and dates of ancient history show that there has always existed, since year 1, a number of men who have kept correct years. The dates of lunar years take care of themselves.

**J. B. Dimbleby.**

The Shrubbery, Chatham-place, Hackney, E.

[23987.]—IT is curious to notice how here and there we find in the world of thought "fossil" ideas and arguments, which, by some strange process of protection, have survived the fate of their brethren. Such a fossil is the old and exploded argument soberly advanced by your correspondent "J. H."

There is not a particle of evidence for his theory that during, or before, or after the Glacial period the world became desolate and *dead*, or that "the present world is a *re-creation* from the past." Such statements would find more fit expressions in the pages of the *Christian Million*, from which he quotes.

The overwhelming weight of geological evidence points conclusively to the fact that the development of the world, physically and biologically, has gone on slowly and surely through a period of time so enormous that the ordinary measurement of years is inadequate to express it, and at no time was this process stayed or its results destroyed universally by the Glacial or any other period.

By this process of development we are inseparably linked with the first speck of organised protoplasm, and we have no evidence of any supernatural creation from then till now. If "J. H." is acquainted with glacial phenomena, he must be aware that its effects are *local*, and can be determined geographically by well-defined boundaries. That whilst the North of England and the whole of Ireland and the North of Europe was shrouded in a vast sheet of ice, the land south of the Severn and the Thames, and the South of Europe generally, was perfectly free from glacial conditions; and he will not find any evidence of glaciation in these districts; yet it is with these districts, particularly the South of Europe and Asia Minor, we have to deal when considering the question of the origin of man. And we have every evidence to believe that whilst glacial conditions prevailed in their greatest intensity in one district, other regions were free, and supported vegetable, animal, and human life.

It is very instructive to be told "simply" "the reason why geological times are not mentioned in the Scriptures." May we ask "J. H." by what process of "clairvoyancy" he became acquainted with the "reason why" the writer of the Pentateuch stated some things and omitted others?

In considering the Genesis of theology and the Genesis of science in their relation to each other, we have first to ask on what basis of fact are they both founded, and I hope, in our mutual interest, that "Priam" will either substantiate or withdraw his interesting statement as to the authorship of Genesis I., and from whence did it come. It is interesting to note in the face of this discussion that the temple of Denderah, in Egypt, contains frescoes representing the various acts of creation as described in Genesis I., and as Moses was "learned in all the learning" of the Egyptians, he may have heard it in the colleges of Heliopolis.

John Hampden must remember that "the highest authorities of the last 6,000 years" have often been wrong. The highest authority of "the highest authorities of 6,000 years" could not repress the genius of Tycho Brahe, of Galileo, of Copernicus, and of a host of others, and the "highest authorities" have, in the long run, to reconstruct their theories, and that repeatedly. "Antiquated authority" often means *antiquated error*. He also states that "of course the story of Adam and Eve is Mosaic." This may be; but *why* "of course"? What proof can he offer?

I am looking forward hopefully to this discussion that we may obtain some clear and well-supported account of the origin of Genesis I., and of the authority it bears. When this is determined we shall have all the materials before us for an impartial consideration of the question of the "Origin of Man."

**A Fellow of the Geological Society.**

[23988.]—ACTING on "A Fellow of the Royal Astronomical Society's" excellent advice to your correspondent "O. J. L.," I have looked up the "simple illustration" in Genesis v.

| | | |
|---|---|---|
| Verse 25 says: | | |
| Age of Methuselah at birth of Lamech.. | 187 | years. |
| Verse 28: | | |
| Age of Lamech at birth of Noah........ | 182 | „ |
| Chapter vii. verse 6: | | |
| Age of Noah at time of the Deluge ..... | 600 | „ |
| Total.... | 969 | „ |

Chapter v. verse 27;—*All* the days of Methuselah were 969 years, *and he died*.

Am I to suppose Methuselah was resuscitated, as "F.R.A.S." says he survived the Flood; whereas Genesis distinctly states the year of that event to have been the year of his death?

I am rather disposed to think "F.R.A.S." has given more "attention" to the "Short History of the English People" than to the book he quotes.

**Chas. J. B. Findon.**

[23989.]—WILL "A Fellow of the Royal Astronomical Society" kindly say how he infers from Genesis v. that Methuselah must have survived the Flood?

May I suggest to Mr. Hampden that "Priam's" opinion may be none the less true because anonymous, and also that everyone now is at perfect liberty to accept or dispute any dogma. Coercion in religion is happily a thing of the past. Mr. H.'s "highest authorities" are probably the same who taught that the earth is a flat box-like parallelogram, that the firmament is supported by immense walls, that above the firmament is heaven, where the angels live, whose business it is to push and pull the sun and planets to and fro, &c., with very much more of equal truth and value.

I would recommend all interested in this discussion to procure Dr. Zerffi's lectures on "Pre-Adamites: or, Prejudice and Science," and "Long and Short Chronologists: or, Egypt from a Religious, Social, and Historical Point of View."

**E. C. C.**

[23990.]—GEN. i. 1, 2, expressly says that before the seven days there had been a creation that had been thrown into confusion. The exact words are: "The earth was *tohu ve bohu*," which is very like our "topsy-turvy."

After the Fall there were two sorts of men on the earth, "the Sons of God," and "the sons (or children) of men" (vi. 2); that is, there were descendants of Adam and Eve who still retained the perfection which the latter had forfeited, and there were a race of men that were "of Adam's own image," which no longer was completely after the image of God, and through the union of these two races, all mankind became inheritors of the curse pronounced on Adam.

That Adam and Eve had children whilst in Paradise is as good as declared in the *command* that was given them at their first interview, to be fruitful and multiply, and, as your readers will remember, Milton introduces a scene that *ought* to have led him on to a statement to the same effect. If Adam and Eve were long in Paradise—and they may have been there at least a hundred years (iv. 25, v. 3)—there would have been many of the better and wiser race in existence at the time that Cain "builded a city," and he may have learnt how to do so from them.

Has not "F.R.A.S." made a mistake about Methuselah? Gen. v. 25, says that he was 187 years old when Lamech was born; v. 28, that Lamech was 182 years at Noah's birth, and vii. 11, that Noah was 600 years old when the Flood came, which would make the year of the Flood coincide with that of Methuselah's death, which occurred in the 969th year of his age. If

"begat" is taken literally, he would have died a year and a half before the flood, which would then have to be reckoned as occurring in the 971st year.
**K.**

### BORT.

[23991.]—"Z Y. X." gives us further interesting particulars. I cannot find the account of Dr. Robinson's use of his daughter's diamond for the purpose of turning up the hard steel pivots of his telescope. The letter signed "B. P. A." appears in the English Mechanic for Jan. 15, 1869. Perhaps some reader can give the reference to Dr. Robinson's use of the diamond, and I will look it up and write again. There is no doubt that a diamond tool can be used to cut hard steel. The question is, Can it be used practically with any such advantage as to supersede the use of the revolving emery wheel? I say not. But on that question many readers will be glad of further data.

Upon the Dessau nickel diamondiferous tools, I see, under the microscope, that the surface is armed with clear transparent diamond crystals of minute size, but not giving much clue to the system to which the crystals belong. Probably "bort" is one of the substances which does not escape adulteration. If any reader will kindly send me a minute portion of powdered bort, or powdered carbonado, or other of these materials which he is using, I will examine it under the microscope, and report it in "E.M." **James Edmunds.**

Grafton-street, Bond-street.

[23992.]—"S. E. S.," letter 23932, speaks of a black diamond. Does he not mean carbonado, or carbonate, which is not crystallised, but amorphous.

Many years ago the carbonado was used for dressing millstones, and I know it has been used since for cutting stones.

What I want to protest against is that the stuff should be called diamond, unless in a popular sense, such as when coal is called a black diamond, because diamond, carbonado, and coal have all a common origin—viz , carbon. **Z. Y. X.**

### NEW MIDLAND ENGINES.—TO "FIREMAN."

[23993.]—"Locomotive" (letter 23943, p. 35) has so covered the ground in his letter that practically he answers all the points raised by "Fireman." "Expansive working" has changed these engines, which were called "big failures," into "big successes," and all in a few days, and without *any* alteration in the engines themselves. I know well that if the engines had had larger boilers they would have done better, but I can't stand by and see fine engines run down and called "big failures," just for want of "expansive working." Where I blame the company is not for making the engines, but for not informing the drivers that they wanted working differently and more expansively; if all this had been told at first, there would not have been all this bother, and the fine engines would not have got a bad name; anyhow, all's well that ends well, and now the 1667 class are doing as fine work as the 60 or 800 classes, so I have only got to say in conclusion that I am now more than ever in favour of

**More Expansion.**

P.S.—"Fireman" gives a set of conditions that the big engines do not get into—they are "linked" well up, worked more expansively, and, instead of losing time and taking pilots, they are taking their trains to time, don't want a pilot, burn less coal, and have lots of steam. What a change in ten days!

### BRAKES ON THE G. and S.W.Ry.

[23994.]—Mr. W. B. Thompson (letter 23941, p. 34) has evidently come to a hurried conclusion that the G. and S.W. Co. is going to change its brake. Nothing of the kind; it is going on fitting the Westinghouse as fast as possible. The company has got one vacuum train fitted just as an experiment; and it has some carriages with both Westinghouse and vacuum, which used to run over the Midland to Bristol, and over the Lanc. and Yorks. Ry. The lines that interchange at Carlisle are G. and S.W., Caledonian, North British, North-Eastern, Midland, North Western, W.C.J.S., and M.S.J.S.; and as they all run Westinghouse fitted stock to Carlisle there is no trouble in exchanging at that place. **Loco.**

### NEW BRAKES.

[23995.]—I think that certain misstatements made by "Driver" (in 23907) in your issue for March 6 ought to be corrected; these refer to the London, Tilbury, and Southend Railway.

This company never fitted any new stock with the chain brake, the only stock fitted being some which originally belonged to the North London Railway, and was handed over to the Tilbury line in that condition, and they have at present no intention of taking it off.

The Westinghouse automatic is thus the only brake adopted, and this has been done after mature consideration. **Loco. Draughtsman.**

### DYNAMO.

[23996.]—I can assure Mr. Eaves that I do not intend to go on with the making of the dynamo after the instructions at present to hand, as they are not so clear as I think would justify me in laying out a largish sum of money. I, however, have no right to complain. I beg to point out to Mr. Eaves that I stated very distinctly on Jan. 2, in letter 23704, that I wanted to light 16 glow lamps of 20 c.p. each; and on Feb. 6, in query 55839, I asked for information as to shunt winding, for obvious reasons. If Mr. Eaves would give me that information, I should certainly feel much obliged to him. I like this kind of work very much, and have every facility for carrying it out. I should prefer the construction given in No. 1007; but would not adhere rigidly to that shape if another and better is proposed.

March 14. **Anglo-Dane.**

### ETERNITY OF MATTER.

[23997.]—How do those who believe in the eternity of matter get over the following difficulty?

The material universe has been cooling as long as it has existed, so the further we trace it back the hotter we find it; it could never be more than infinitely hot, but it can be shown that it would not take an infinite length of time for the universe to cool down from an infinitely hot state to its present state. For suppose it to have been infinitely hot at one time, then in a moment it would have cooled down to a finite heat, and it can only have taken a finite period to cool down from any finite heat to its present heat, no matter how slow the cooling; therefore, the present course of events called Nature has not always existed. **A. W.**

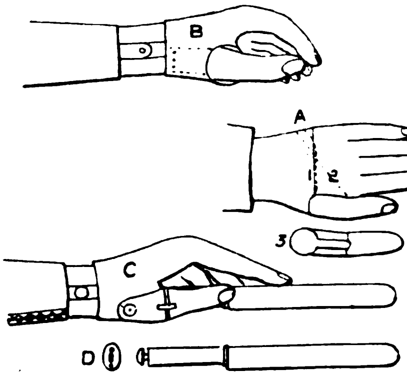
## REPLIES TO QUERIES.

⁂ *In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[54745.]—**Rising Logarithms.**—There is often a table thus headed in Epitomes of Navigation by which to find the hour angle from the meridian. It contains the logs. of the square of the sine of half the arc, thus: rising log. of 28° or 1h. 52m. is 18·767350, which, divided by two, gives 9·383675 the log. sine of 14°. The above does not correspond with the logs. quoted by Mr. Ruppel in 54994, but it may afford him some clue to what he wants.—Alfred Dobson, Blenheim, N.Z.

[55323.]—**Musical Scale.**—I must apologise for the error in my letter on page 564, which was written hurriedly. I could not refer to tables while writing, but discovered the mistake in calculation just after, and sent a correction to our esteemed Editor. It must either have arrived too late or not have been clear enough, as my letter appeared in its original form. It is true that the two "semitone intervals" (I don't like this term) are of equal magnitude in the division of the diatonic scale as proposed by Mr. Walter Hardie—viz., as 243 is to 246; but my objection to this division is that such a ratio between two sounds of the musical scale is too complicated to be naturally correct, and it can be correct in no other way. The very essence of music is simplicity of ratio between the vibrations of the notes used, and complexity is unintelligible to the musical ear. There is far more simplicity in the ratio 15 to 16 than there is in that of 243 to 246, which is a comma ($\frac{80}{81}$) smaller; and this simpler ratio for the note sensible is secured by introducing one small tone ($\frac{9}{10}$) in each of the two tetrachords into which the scale is sometimes divided. There are also other complex ratios entailed by Mr. Hardie's division, as, for instance, the major third is in the ratio of 64 to 81 with the keynote, instead of being as 4 to 5; the major sixth as 48 to 81, instead of as 3 to 5; and the major seventh as 128 to 243, instead of as 8 to 15, all being a comma too high, and the minor thirds between E and G and between A and C are necessarily each a comma too small, being in the ratio of 27 to 32, instead of 5 to 6. In melody, as well as in harmony, the endeavour of musicians is to produce pure intervals—that is, to produce intervals with simple proportions; and although it has been noticed that there is a preference for taking the great tone when choice is offered, yet the ear is ever comparing with the key-note, and makes this adjustment of a comma wherever necessary. The natural scale does not contain two intervals of a like magnitude side by side, neither is any greater interval made up of two similar smaller intervals. I am glad to see this question to the fore again, and in view of the forthcoming Exhibition of Inventions, a little acquaintance with the subject will enable those interested in pure intonation, as applied to keyed instruments, in some measure to understand the aim and intention of any exhibits of this character that may be found there. I am hoping that this branch of art will be well represented, and receive a strong impetus.—S. E. Hunt.

[55316.]—**Artificial Hand.**—Like "D. P.," I have a friend who met with the loss of his hand, rather nearer the wrist than shown on "D. P.'s" drawing. He tried the best makers of artificial hands on this side of the Atlantic, and all, without exception, proved useless as far as doing any real work was concerned. We then set to work to make a hand which would enable him to handle a knife or a pen. Our first attempt was similar to B. Noticing that he had considerable movement in the remaining portion of the bone above the thumb, it struck me that he could utilise that motion if something were clasped around it similar to the manner of holding music with the patent springback holders, so we made a hand with rigid fingers and a thumb, as shown at A3, which was attached to the inside of B by leather to give it flexibility. This worked well, and very natural for light work, but his hand being amputated so far back as A1, the spring grip had not the hold which I hope "D. P.'s" friend, at dotted line Fig. 2 would have. The style he now uses is shown at C—fingers rigid; thumb works on a joint purposely exposed to show working; A is opened or closed by a neat thumb-screw, to hold a knife; A is first inserted into D, and given a quarter turn, and then the thumb-screw binds A between thumb and index finger, as shown in the drawing. The hands are fastened on the usual way, with a joint at the wrist and laced leather band above. Hope some of these will prove of use to "D. P.'s" friend.—Andrew Leitch, Hamilton, Canada.



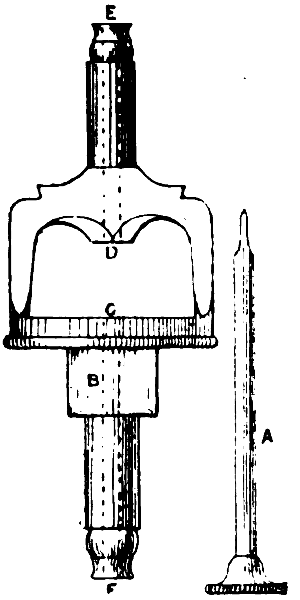
[55384.]—**American Organ.**—To "H. M. I. R."—Thanks for reply; the plan you have adopted is no doubt the best when the instrument will admit of it; but in most cases there would be a difficulty in finding room for the windways for the added set. As regards Munro reeds, I believe they are about the shortest in the market, and I think are all made to one scale. Should consider them very suitable for organette; in fact, I have seen them so used in an organette of American make.—J. E. Floyd.

[55571.]—**Turbines.**—In answer to "E. F.," the arrangement proposed will work, provided the draft tube is not too long, and everything is tight. If, however, any leakage takes place, the draft tube, unless perpendicular or nearly so, will require refilling with the valve closed. Is the saving in excavating, partially balanced as it is by the cost of the valve, worth the risk of leaky packing, &c.? A vertical draft tube is better than a horizontal one, because it is shorter, and need not be so large in diameter; hence the velocity of the effluent water is greater, and will carry off any small quantity of air which may leak in. If the velocity is not sufficient for this purpose, difficulties may be expected.—Chas. Louis Hett.

[55723.]—**Gramme Dynamo.**—To Mr. S. Bottone.—The frame I have made for above dynamo is the usual upright Gramme pattern—11in. high, 10in. long, and weighs ¼cwt.; the field magnets are cast with the pole-ends on; the arms of field magnets are each 3¼in. long by 1¼in. diameter; the pole ends are 1⅛in. wide and semicircular; the ring (Pacinotti form, with 12 cogs) is 3in. inside measure and 4¼in. outside diameter (including cogs). I have Nos. 16 and 18 D.C C. wires, and require machine for incandescent lighting and experiments.—Gramme.

[55813.]—**Land Drainage.**—Practical experience in land drainage might be obtained in many counties; but our friend "Paddy" should not omit Lincoln or Cambridge. One of these and Yorkshire could, I should think, give him all the experience he would need. He should, first of all, read up such books as Scott's "Draining and Embanking," published by Lockwood and Co.—Nun. Dor.

[55702.]—**Watch Pivot Holes (U.Q.).**—I send the following sketch to "Josefus." A is a steel rod accurately turned and finely pointed, which fits in the long hole indicated by dotted lines. There are sometimes three or four of these steel rods. The uprighting tool is made of brass or gun-metal, and its beauty and worth consist simply in its accuracy. B is just a square for the purpose of holding it in the vice. Now, supposing we had to plug up the top centre wheel hole in a Swiss watch, we simply put one of these steel rods into the hole with its point coming out at C, on which point you could rest the bottom plate-pin, insert another runner from the top, and where the point touches is the place to drill the hole.—ANNIE.



[55827.]—**Gravity and Dead Escapements.**—The "Country Parson" now asks me to point out something or other to him from my book. I shall do nothing of the kind. I am always ready to answer *bonâ-fide* inquiries about clocks, if I can, without too much trouble, for persons who show that they have really attended to what I have written and seem capable of understanding more. But I shall not answer a *malâ-fide* question from a man who first gratuitously and anonymously published that my book is "distinctly wrong" in saying what it never has said in any one of the editions; and then, when he is made to see that, does not apologise in the smallest degree, but takes refuge in saying that the sentence he quoted wrongly at first "without doubt conveys a wrong impression." Very likely it does to those who do not choose to attend to my words, which Mr. Brock tells me, again, are perfectly correct, except as to one gravity regulator in which a customer wanted some expensive additions of his own for electrical connections and other things. I have already given the numbers of the pinions in all those clocks that I have had, and all other necessary information, as to what they require, and in what respects I have found them superior to dead and single-beat escapements, and in what respects not superior. I shall not repeat them for a man who only wants to find a pretext for some more contradiction in order to cover his own carelessness and rudeness.—EDM. BECKETT.

[55834.]—**Punching Machine.**—Machines of the kind can be seen at any boiler factory, and illustrations in the lists of makers of machine tools. —T. P.

[55849.]—**Brazing Steel.**—File the surfaces clean; cover with powdered borax and spelter, and pinch the parts between brazing tongs—that is, tongs with broad and heavy beaks, which are made nearly white hot. You can also braze with the blowpipe.—ESSAR.

[55850.]—**Cover for Flywheel.**—What kind of advice is wanted in this case? "Soho" has simply to rivet up some sheet iron into the half of a circle —say, 16ft. 6in. by 8ft. 4in.; repeat, and join the two by riveting a strip, say, 2ft. 2in. wide, having a flange of about 1in. at each side.—T. P.

[55853.]—**Printing Press**—I do not know of any test experiments to ascertain the pressure per square inch on the table and plates of an ordinary press; but it must be something considerable. The querist will have no difficulty in procuring a press to do the work he requires, which is really a very small job.—A PRACTICAL PRINTER.

[55858.]—**Volt and Am. Meter.**—This querist will find an am. meter on p. 62, and a voltmeter described on p. 568, Vol. XXXIX. I have no doubt there are many others described in back numbers, but it is advisable to purchase instruments if accuracy is required in the tests.—NUN. DOR.

[55860.]—**Length of Metal for Cambered Springs.**—I don't think there is a rule. We cut the thing out in hoop iron; bend to exact shape required, mark off the length, straighten out, and there is the gauge.—ESSAR.

[55866.]—**Chemical Stamping.**—It might be possible to do something of the kind with chloride of cobalt; but it is scarcely probable, as such a device would be utilised in many ways, and would certainly be patented.—F. I. C.

[55867.]—**Feed Pump.**—Cannot this querist drive his pump by connecting it with a small shaft driven by a large pulley to reduce the speed. The dimensions, number of strokes, &c., must be calculated according to the rules and plan adopted; but the rules can be found in "Molesworth's Pocket Book."—ESSAR.

[55870.]—**Optics with the Lantern.**—To "EXCELSIOR."—I for one shall be very glad of the drawings you mention. Will you also tell me which form of lime you consider best, the cylinder fixed on a pin, or the pieces wedged into a circular brass ring?—GRAPHO.

[55870.]—**Optics with the Lantern.**—By a printer's error I am made to say "I get a parallel beam when the principal tube jet is ⅛in. from condenser." This should read "I get a parallel beam when the knuckle of jet is ⅛in. from condenser."—W. H. SHRUBSOLE.

[55870.]—**Optics with the Lantern.**—To L. WRIGHT.—Many thanks for your answers. I am still puzzled at my failure, as I am sure that I use prism at proper angle. I shall take your advice and use the mixed gases. Will you help me in another experiment? I cannot get reversed sodium line satisfactorily; I use in front on lantern a large square biscuit-tin cut in two, and sliding camera fashion—one half fits front of lantern, and the other has a large slit cut in it. I also have adjustable slit on lantern front. How far do you actually place the sodium flame from lantern front in the experiment, as described in your book? I hope I am not troubling you too much; but your book has much interested me, and I do not like to be beaten. Many thanks to "Excelsior." If the Editor will permit, I shall much like description he offers. Mr. Shrubsole will perceive that I have Mr. Wright's book; in fact, my original query was on an experiment described in it. Perhaps Mr. Shrubsole, having worked through the book, can give me a hint which will help me with respect to reversed sodium line.—S.

[55876.]—**Improving Light in Coal-Gas.**—Many thanks to "Arvonia" for design and information about carburetter; but before proceeding to manufacture, will he kindly state whether the size given is not too large for ten flat flames, not Argand flames? Also how long the cotton wool will remain saturated with benzoline, especially the upper layer, seeing that each layer is cut off from the reservoir of benzoline, and there is no means of using capillary attraction for re-moistening after once becoming dry. Supposing your design will suffice for, say, ten flat flames, how long will one charging with benzoline last? Because if it is necessary to daily moisten the cotton wool in the trays by refilling from the top, it has occurred to me that a slight improvement to meet this end might be arranged by passing a large cotton wick from each tray down to the reservoir of benzoline. Will not cotton wool after a time, by its own weight, become too solid or dense?—WOOLWICH GAS.

[55896.]—**Heating Room with Steam.**—It is difficult to give "Novice" the information he seeks with accuracy upon the details furnished. He will, however, require about thirty-eight 17ft. lengths of 2in. pipe, which, with the bends, will give about 680ft. run. Steam at as low a pressure as 10lb. may be used, but if he can obtain 40lb. or 50lb. so much the better. The pipes should be placed under the floor, and about one quarter the area of it at a point furthest from the cold air inlet should be perforated, so that the heated air may ascend. After passing through the room, the moistened air should be drawn off by being connected to a flue, a proper feather being introduced in the usual way. If my explanation is not clear, I will supply a sketch. See my reply to 56049.—F. C. S.

[55905.]—**Cores.**—I notice some errors on page 116 regarding the above—viz., at line 18, read "lay in the core bar"; at line 20, leave out the semicolon; and at lines 21 and 22, read "adjust screwed chaplet and socket in top part," and leave out the comma after chaplet.—ASTERISK.

[55935.]—**Electro-Chemical.**—I have no wish to hurry Mr. P. Ward as to the publication of his researches; but I am curious to know how he measured the E.M.F. of "several million volts," and how he contrived to cause a current of 30 h.p. in the primary to yield a current of 1,000 h.p. in the secondary. It would be very convenient to have a means of making 30 h.p. do the work of 1,000 h.p. —WM. JOHN GREY, F.C.S., Analytical Chemist, Newcastle-on-Tyne.

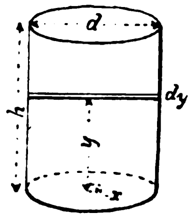
[55947.]—**Pressure of Water in Pipes.**—In glancing through the reply of G. Worlands to this query, I find that he has, in the second part of it, reproduced an error (the result, probably, of a misprint) from, I think, the "Colliery Manager's Calculator," in the formula for finding the number of gallons of water delivered from a borehole. The number of cubic feet discharged per minute is $= v \times \cdot 7854\ d^2$; and as there are 6·25 gallons in a cubic foot, the discharge in gallons is manifestly equal to $6 \cdot 25\ v. \times \cdot 7854\ d^2$. This indicates the evil of replying to questions without an adequate knowledge of the subjects to which they refer; or of placing such implicit reliance on what is contained in books as to take for granted, without question (as in the present instance), a formula containing an error of the most palpable kind, which should have been detected at once even by the merest tyro in hydraulics.—LYONS.

[55969.]—**Problem.**—I am afraid that in his answer to the above in your last issue "Weiv Revir" has fallen into error, and has worked out (correctly) the answer to a different though somewhat similar question—viz, the time required for the discharge of a vol. of water = the contents of the vessel when the head remains constant. In this latter case we have, as he states in the formula:—$Q = M S V T$ — the letters having the same signification as given,

$$\therefore T = \frac{Q}{M S V} \quad \ldots\ldots\ldots\ldots\ldots\ldots \quad (1).$$

But in the problem the vessel receives no additional supply, and the head consequently varies. Now, suppose the contents of the vessel to be divided into an indefinitely large number of layers, the indef. small interval of time occupied by one of such layers in descending through a height equal its own thickness—i e., for the discharge of one of such layers—is obtained by equation (1), since in such a case we may assume the head to remain constant, the distance $dy$ being inappreciable. In Fig. 1, let $dy$ represent such a layer, situated at a height $y$ above c.gr. of opening; the other dimensions being as given in question:

FIG 1.



$$\text{Vol. of layer} = \frac{\pi}{4} . d^2 . dy \text{ cub.-ft.}$$

$$\text{Sect. area of opening} = \frac{\pi}{4} \cdot \frac{x^2}{144} \text{ sq.ft.}$$

$$\left.\begin{array}{l}\text{Veloc. of descent}\\ \text{of layer in question}\end{array}\right\} = \sqrt{2 g . y} = 8 \cdot 074 \sqrt{y} \text{ft. per sec.}$$

$$\text{Constant} = \cdot 67 \text{ as assumed.}$$

$$\therefore\ dt = \frac{\frac{8}{4} \times d^2 . dy}{\cdot 62 \times 8 \cdot 074 \times \frac{8}{4}\ \frac{x^2}{144} \times \sqrt{y}}$$

If we integrate the above expression we obtain the whole time $t$ required for the vessel to empty itself—i.e.,

$$t = \frac{144}{4\ 975} \times \frac{d^2}{x^2} \int_0^h \frac{dy}{\sqrt{y}}$$

$$= \frac{144}{4 \cdot 975} \cdot \frac{d^2}{x^2} \times h\sqrt{b}$$

$$\text{or } t = 57 \cdot 88 . h^{\frac{1}{2}} . \frac{d^2}{x^2} \text{ seconds.}$$

The above result is just double that obtained by "Weiv Revir," and proves what was pointed out by "M.I.C.E." in his solution.—C. Mc +.

[56025.]—**Trueing Grindstone.**—Has not "Fair Dealing in Monopoly," who says he is a patentee, allowed his feelings to get the better of his judgment? If he knew so much as he now discloses, why did he ask for the information in our columns? Now, I suggest a common—very common—rough slide-rest, carrying a piece of carbonado at the end of an iron tool. This will true up any grindstone of any kind, whether Newcastle, Welsh, or even emery!—Z. Y. X.

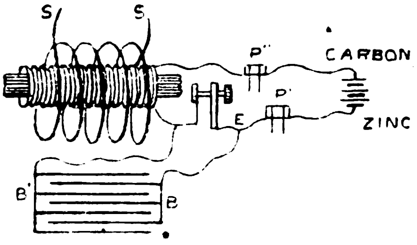
[56026.]—**Trueing Grindstone — Patent Law.**—Having been accused (p. 255, Vol.

XXXIX.), of being in the interest of the telephone companies (I do not know whether there is one or two), I hope I shall not be misunderstood if I venture to demur to the phrase, the "socialistic tendency of the times," which your correspondent "Z. Y. X." introduces (p. 40) in a reply under this head. I do not admit the existence of any "socialistic" tendency (whatever that may mean) that has not existed at any time since monopolies were first granted. There is no more tendency in "ours" to "get at trade secrets and the mode of getting round a patent" than has existed at any time within the memory of "Z. Y. X." and myself. I yield to no one in a just recognition of the rights of a patentee; but knowing what I do of patents and patentees, I confess to some degree of smiling when a would-be monopolist finds that his "invention," as he is pleased to consider it, is as "old as the hills." In this very connection—a machine for trueing a grindstone—I am confident there can be nothing better than the old plan pursued for generations by our forbears; and if some one has devised a means of putting the bit of iron into a rest or guide, I can only say that he may be entitled to claim the exact way he has done it, but he cannot prevent any one else doing the same thing in a different manner, because there is really no "invention" about it. The thing has been done hundreds of times, and "all honour to 'Marcus'" means no honour at all, unless it can be shown that the machine or apparatus in question is a real invention. As to the telephone business, no one regrets more heartily than I do that the battle was so easily ended, for I look upon Reis as the real inventor, and consider Bell as the merely successful adapter, just as Watt was with the steam-engine, though I suspect Watt expended more brain-tissue than ever Bell did. When we are all dead and gone, the impartial historian will wonder how it was that no one apprehended the importance of the facts Reis communicated to a well-known English electrician until Bell unearthed them, and, in a race with Edison, Gray, and others, managed to get the first patent. I have not the slightest commercial interest in telephones; but I suspect that I regret more than those who are so anxious to make use of the outcome of other men's brains, the result of the trials in this country, for they have given Bell, or his representatives, a practical monopoly of the telephone, and put a stopper on its development for 14 years from 1876. It is not these cantankerous quibblers—these miserable copiers of other men's work—the public have to consider; but those who really help in the march of progress by improving upon the ideas of others, and the latter have been stopped because the decision of a judge has given the monopoly of the principle to Bell, whereas, as it seems to me, he was entitled only to claim his method of carrying out Reis's idea. Money, as a matter of course, now carries the day; and who is prepared to fight the monopolists who have bought up every device which threatened to rob them of their monopoly? That is no fault of the patent law; but is due rather to that greatest and worst of trade-unions—the lawyers—which makes it impossible for the impecunious to fight against those who have money, even though all the equity is on their side. Having thus relieved myself, I would say that "Z. Y. X.," in quoting the actual words of the prohibition clause, goes too far, for it has been held that one may make a patented invention for the purposes of experiment, but must not use it in the sense of beneficial user. That is, to take the telephone, one may make a telephone, and even exhibit its capabilities to friends; but he must not, for example, lay it on to his stables to call his coachman, as that would be a beneficial user. The law, on this point, is very clear, and there are numerous cases to exemplify it. You may make any patented invention you like for the purposes of experiment; but you must not use it in the ordinary sense of the term. It seems to me that the law here is very definite and satisfactory, for the sole object of granting a patent is to promote invention, and that would be almost impossible if one could not make and use a patented device by way of experiment.—NUN. DOR.

[56033.] — **Regulating Shocking Coil.** — "S. D." might regulate the strength of the shock obtainable from his coil by having the zinc plate more or less immersed in the dilute sulphuric acid in the outer cell of his battery; it would also be better if he were to actuate the contact-breaker with a small electro-magnet, separate from that in the coil, as the introduction or withdrawal of that magnet from the coil greatly varies the strength of the secondary current (therefore, of the shock obtained), it being weakest when the magnet is withdrawn.—J. KEAN.

[56033.]—**Shocking Coil.**—Make one glass cylinder 10in. long, ½in. inside diameter, cement a brass cap to each end, make a hole through one end for a brass rod to slide in, which must be a little longer than the tube, so that it can be brought in contact with the bottom plate, then fill with water and stand up; join wire from coil to one plate and wire from handle to the other, start with rod right up and slide down gently. Water, being an imperfect conductor, offers a greater resistance to the current, as the electrodes are separated.—C. H. CARTER.

[56037.]—**Induction Coil.**—It is almost impossible to explain to W. G. Glasgow the precise cause of his inability to obtain strong shocks from his coil. I should think it very probable that there must be a connection between two, or perhaps more, layers of his secondary wire, so that the current, instead of going *through* each layer, passes from one to the other, thus shortening its should-be journey; and this is very important, as the circulating of the secondary current round itself in the separate layers of wire greatly intensifies it; or, perhaps, this thin wire has had a sharp twist or bend together; either of which will sometimes materially decrease the strength of a current on account of the increased amount of resistance offered to it; or, again, is W. G. G. sure that his batteries, contact-breaker, and primary coil are all right? Now, with regard to the condenser, the annexed diagram will, I hope, help to explain it.



Let P′ P″ be the terminals of the primary coil, M the soft iron core, and S S′ the terminals of the secondary coil; the primary terminal P′ is connected to a series of sheets of tinfoil B, connected together along one edge, but separated by sheets of paraffined paper from a similarly connected series of tinfoil sheets B′, which are connected to E; this arrangement and connection of tinfoil sheets constitute the condenser, which is, I might say, always placed in the wooden base of the coil; the base being made hollow to receive it.—J. KEAN.

[56037.]—**Induction Coil.**—It is impossible to tell the reason why the induction coil will not give good results. Possibly the wire of your secondary is too thick; examine connections and contact breaker. A condenser for an induction coil is made thus: Take many sheets of tinfoil and paraffined paper, arrange in alternate layers, connect together the 1st, 3rd, 5th, &c., of the tinfoil sheets, and also connect together the 2nd, 4th, 6th, &c.; then connect each of these series to the ends of the primary coil. You will get good contact by screwing a piece of wood firmly across the edges of the tinfoil. —J. RANCE.

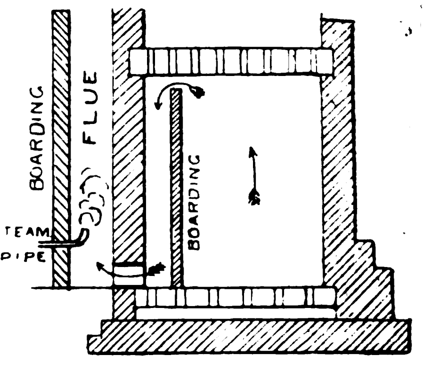
[56040.]—**Knocking in Gas-engine.**—When we first started our ½ h.p. Otto we experienced the same annoyance until our old millwright turned his attention to the key of the flywheel. On this being driven tight home, the thumping noise ceased. See that bearing at crank end of connecting-rod is not too loose, and, if necessary, slightly tighten set screw at the other end. Don't be afraid to drive key well home. Our engine has run splendidly ever since, with no trouble. — AUBERT, Guernsey.

[56041.]—**Gun Metal.**—Is "Nun. Dor." poking fun at us when he suggests that gun-metal is sometimes made of a mixture of copper, tin, zinc, and iron? Is it really the fact that these four metals can be melted together? I thought that in making gun-metal the difficulty was to prevent the zinc being dissipated by the heat required to melt the copper; but will not this difficulty be insuperably increased if iron is to form one of the ingredients? Is it a fact or a slip?—Z. Y. X.

[56046.]—**Turning Spindle.**—The apprentice's difficulty may arise from one of many causes: 1. It may arise from his lathe centres not being true to each other. 2. It may be from careless punching of the holes at each end. 3. It may be that the centres on mandrel and poppet are not of the same angle; but probably he will find that 4 is the true solution—viz., that he did not drill the holes at each end deeper than the centres, so that the centres bottomed the hole. This is the cause of much bad work. The point of a centre ought never to touch the metal which is being turned.—Z. Y. X.

[56048.]—**Burning Bricks on Wet Ground.** —The heat draws the damp from the ground. Pave the bottom of the kilns with hard burnt bricks. In "setting," put a course or two of burnt bricks at the bottom, and let the green bricks be well dry. Set them so as to have plenty of bottom draught. Fire slowly and carefully at first, and try well for steam before getting the fires away, so that the bricks will not be "boiled" before they start to bake.—BURNER.

[56049.] — **Laundry Man.** — The moist air should be tapped off from the top of room by means of a flue.



Plain deal boarding will suffice if no chimney exists, a small jet of steam being turned in to create a draught; exhaust steam from engine will do.—F. C. S.

[56057.]—**Ornamental Bricks.**—Various kinds of ornamental bricks can be made direct by brick-machines, such as Bevels, Plinths, Bull-noses, and Moulded bricks, Dog-tooth, Nail-head, &c., and Floriated bricks; and Floriated, Martini, Gillebone, and Indian tiles must be pressed, and require special boxes, plates, and blocks, varying according to the size and pattern of the goods required. The blocks and plates are best made of cast iron, wood will do, but soon gets worn. I shall be glad to give "Brickmaker" further information if required, either through the "E. M." or privately, if he will advertise his address.—BURNER.

[56058.]—**Tires.**—The work of a steel tire is represented by the distance run. An eminent maker has deduced this formula $W$ = weight in pounds, $M$ or mileage $= \frac{W \times 248{\cdot}55}{2{\cdot}2048}$, which gives for all practical purposes 115 miles for every pound weight of the tire.—R. B. HANSELL.

[56063.]—**Brazing Bicycle Fork.**—File the surfaces of broken parts flat, clean well from foreign bodies, such as grease, oil, or dirt, bind on (with binding wire) two strong pieces of iron wire so that the joint will be held firmly together. The filed faces must touch each other in all parts, else you can't braze. Get borax and mix with clean water so as to form a thick paste; smear the parts to be mended with this solution; get two or three small pieces of (soft brass) is best, lay them on the joint, put into furnace or strong fire, and as soon as brass has melted the joint will be complete.—ANNIE.

[56064.]—**Troublesome Battery.**—If Mr. J. Parsons were to remove the zincs from his cells, take out the binding-screws if they will come, then clean off the white fibre and afterwards coat the top of the rods and about ½in. down with Brunswick black, I think he would find the nuisance effectually prevented. I tried this on a Leclanché battery which I made early last year, and on reading Mr. Parsons' letter I went and had a look at it to see if I could find the same thing, but there it is as good as when I put it up. I have done nothing to it since September last. I may say that it does only bell-work. Mr. Parsons gives no reason for wanting to use old charge in new pots; if the old charge was working all right where it was, it may, of course, be effectually used again.—J. KEAN.

[56081.]—**Baffled.**—I fear that "Baffled" will not be able to work a reliable contact with suspended astatic system as shown. If the needles are pivoted at both ends, a firmer contact can be obtained; but the needle is very apt to rebound, and, on the other hand, owing to the very small contact surface, it has a tendency to stick to the contact pin, even when a very small current is used. Some years back I made a series of experiments, using a great variety of metallic substances. In every case I found the needle stick, and closer examination showed that fusion had taken place between the metals used. I then tried platinum and carbon, reasoning that since the oxide of carbon was gaseous, I should get over the difficulty. I found this answer perfectly, and patented the use of this form of contact with the instrument concerned. As, however, the patent has expired "Baffled" is free to use it, and I believe he will find it answer well.—A. S. T. E.

[56085.]—**Scroll Chuck.**—Mark jaws and chuck so as to be able to return to right slots. Unscrew till jaws are set free, noticing order in which they come out. The last to be set free is the first to be taken up by screw in replacing. Clean with paraffin oil, dry, and apply a little olive oil before replacing jaws.—GEO. A. WALTON.

[56089.]—**Fasting and the Jews.**—Jewish fasting always implies the strictest abstinence from all food or drink. The Mosaic law appointed one day only in the year for fasting, which was ordained "for the chastening of the Nephesh" (soul). This fast was on the Day of Atonement, and it not only implied abstinence from food and drink, but also from washing, anointing, and the putting on of sandals. In process of time five more fasts were added; but these were not long held, and few entire fasting days are now observed by an orthodox Jew. With the exception of the fast on the Day of Atonement, and the anniversary of the Destruction of the Temple (both of which begin at sunset), a Jewish fast lasts from the break of the day till the appearance of the first three stars. Passover cake is another name for the unleavened bread which is eaten at the feast of the Passover. It used to be eaten in a standing position, as the Israelites had eaten hastily on the night of the Passover, with the loins girt and shoes upon the feet. It is not now eaten standing, except by the Samaritans, who eat it in this way at the summit of Gerizim, and there to this day they will hand to the stranger an olive-shaped cake of unleavened bread inclosing a green fragment of some bitter herb, which may perhaps resemble the sop that Judas received from our Saviour. The healthiness and long life of the Jews are proverbial. It would be difficult to determine whether it is owing to the fasting or not, as any benefit to be had from fasting depends on many things—such as climate, habit, general health, &c. Their temperance, I have no doubt, has much to do with it. Physiologically considered, there is no benefit from fasting for any period of time when the body is in health; but when one has bile, a good "starving" often restores the natural balance.—Bobadil.

[56091.]—**Water Capacity of Boiler.**—Your boiler will require 95 cubic feet of water before appearing in the glass gauge. The answer is easily got by plain figures and a reference to nearly any textbook on mensuration.—Yama.

[56095.]—**Gramme Machine.**—The resistance of the armature depends upon what purpose the machine is intended to be used for. If for an experimental machine or shunt-wound machine for lighting incandescent lamps in parallel, the resistance is abnormally high; it should be less than ¼ ohm; for a series-wound machine it is also high, and should be considerably less if you wish to get good results from the machine. In the latter case the resistance might be ¼ ohm.—J. Rance.

[56096.]—**Amalgamating Zinc.** — You can amalgamate them by moistening them with one part sul. acid to two parts water, then rubbing the mercury on till it appears bright all over. Do this about once every month.—C. H. Carter.

[56096.] —**Amalgamating Zinc.** — This has been answered over and over again in back numbers. Pour the mercury into a dish, and, having cleaned the zinc by washing it in dilute sulphuric acid, rub the mercury upon it with a rag moistened with the dilute acid. The mercury will stick to the zinc and form a bright mirror-like coating on its surface. Or, if you like, you can use this: Dissolve 1oz. of mercury in 1¼oz. of nitric acid and 3¼oz. of hydrochloric acid; pour the solution on to the zinc in a dish, and rub the zinc with a piece of flannel till it is coated with mercury. If your mercury is bright and clean, its age does not much signify.—R. A. R. Bennett, Oxford.

[56096.] —**Amalgamating Zinc.**—Wash the zinc in dilute sulphuric acid, one of acid to eight or ten of water; then pour mercury over it, rubbing with rag dipped in the acid. The mercury will adhere at once wherever the zinc is clean; but give it a good coat, as you can't put on too much. The fumes in the process are unhealthy, so have good ventilation.—Bobadil.

[56098.] — **Grinding V-Tools.**—"Junior" should look at Churchill's catalogue for "Centre Gauge" and for "Watch Charms." Under each head he will find what he requires. The little gauges are cheap and true, and full instructions are given in catalogue and with article when sold.—Geo. A. Walton.

[56100.]—**Oxyhydrogen Lantern.**—To "Invicta."—On p. 15 you will find a description of smith's bellows. The gas bags in question are very similar, with the exception that mackintosh cloth is used instead of leather, and that no valves are used. I am exceedingly out of sorts with an attack of rheumatism, or would go into the matter further; but must try next week to do so.—Invicta.

[56104.]—**Gasoline Gas Engine.**—For the reason stated in reply 56100, I am quite unable to deal with the matter at the moment; but will, if possible, send on sketches in time for next issue.—Invicta.

[56108.]—**Microscopical Staining.**—I know of one place where anything required for this purpose can be obtained—Martindale, chemist. I think the address is Cavendish-street, Cavendish-square, London; but look it up in directory.—Geo. A. Walton.

[56108.]—**Microscopical Staining.**—I believe aniline dyes may be obtained of Messrs. Becker and Co., 34, Maiden-lane, Covent-garden, London. —G. L. M.

~~[56109.]—**Photo. Lenses.**—"Gwent's" len should be quicker than he can expose by hand on good plates. I should recommend him to get the *British Journal Almanac* for 1885, price 1s. At page 250 he will find a diagram of the standard stops recommended by the Photo. Society, and if he starts his largest at No. 14, about 2⅛in. diam., the exact size to produce proportional apertures are given.—A. Pumphrey.~~

~~[56112.]—**Chemical.**—To test wall paper for As, scrape off some of the suspected pigment with a penknife, introduce it into a test tube, and cover it with a layer of charcoal (powdered). Heat the tube where the pigment lies over a spirit lamp. If As is present, a dark ring will be seen to form in the cooler part of the tube, while, higher up still, in the coolest part, some crystals of the oxide of arsenic may be seen.—G. L. M.~~

[56112.]—**Chemical.**—Digest the paper in hydrochloric acid, and boil the resulting liquid with a piece of bright copper foil. A dark stain shows the presence of arsenic; and on heating the stained foil in a test tube, the arsenic is oxidised to arsenious oxide, which sublimes, and may be further examined.—Wm. John Grey, F.C.S., Analytical Chemist, Newcastle-on-Tyne.

[56118.]—**American Gas Bag.**—See my reply to 56100. Will give you and "Oxygen" all particulars you desire.—Invicta.

[56119.]—**Magnitude of Small Stars.**—There cannot be any reliable formula for ascertaining the magnitude of the smallest star visible, because there is no difference between the last star of the first magnitude, and the first star of the second magnitude, and the more minutely you examine the succeeding magnitudes in the same light, the more difficult it becomes to detect any perceptible difference between them.—Star-gazer.

[56120.]—**University.**—This query (?) does not contain a single question.—Wm. John Grey, F.C.S., Newcastle-on-Tyne.

[56122.]—**Small Brace.**—Do you want a hand brace or drill, or do you want it to fix on bench, and must simplicity of construction be a leading feature? I will, then, do my best to help you with pleasure.—Invicta.

[56126.]—**Chemical Examination, London University.** — The maxim, "Never prophesy unless you know," applies with especial force to examinations. The querist should wait until he has time to study the subject properly. Gill's book does not contain very much.—Wm. John Grey, F.C.S., Analytical Chemist, Newcastle-on-Tyne.

[56126.]—**Chemical Exam. Lond. Univ.**—"Londoniensis" evidently wishes to "cram." Let him procure the syllabus and the questions for the last half-dozen years, and he will see at once what to get up.—Geo. A. Walton.

[56132.]—**Cutting Pipes.**—The length BE is same as BF. By Euclid I. 47. $(CF)^2 = (CB)^2 + (BF)^2$ Hence $BE = \sqrt{[(25)^2 - (6)^2]} = 13{\cdot}7477217$. With regard to cutting out in paper when large diameters are required, I may suggest cutting on a diminished scale, say 1in. to the ft.—Geo. A. Walton.

## UNANSWERED QUERIES.

*The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered are repeated four weeks afterwards. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.*

Since our last, "Annie" has replied to 55702.

## QUERIES.

[56137.]—**Tracing Paper.**—Can any correspondent kindly give me a receipt for making a better tracing paper than that made with Canada balsam and turpentine? It is wished to have the paper moderately transparent, but it is still more desirable that it be free from brittleness, and, most desirable of all, that it be perfectly free from all approach to anything like stickiness? To secure the two latter points, I am willing to sacrifice a good percentage of the transparency, if unavoidable.—Jod.

[56138.]—**Plaster and Pipeclay.**—1. What is the composition of which such toys as Father Christmas, Little Red Riding Hood, &c., are made, and how used? 2. What is mixed with pipe clay in the making of common clay pipes that makes it so hard and white?—W. Bennett.

[56139.]— **Boot - Cleaning Machine.** — In our household, as in many others, the number of feet to be kept tidy, is largely in excess of the hands able to keep them so; even these few hands are often enfeebled by very poor health, and by oppressive demands made on their activities in other directions. Any apparatus, then, likely to save labour would be gladly welcomed by us; but we cannot afford to waste any money on costly catchpennies. If any correspondent who has had experience of a boot-cleaning machine, would kindly say whether, or not, he thought it likely to be serviceable in a case like ours, we shall be deeply grateful. A capital washing machine has already done us yeoman's service. Would a boot-cleaning machine be similarly hopeful? — Hopeful.

[56140.]—**Ozone Bleach.**—Can any one tell me where to get, or how to make, Holmes' Ozone Bleach? I find it is a very good thing for washing prints, in the proportion of one part of bleach and ten parts of water.—A. J. B.

[56141.]—**Lobster - Back Cowl.**—Will some kind reader inform me how a lobster-back cowl is put together, so that the front and rim of the head are both the same size? I cannot make one without making the front the largest, through lapping the pieces all one way, from the rim upwards. Is there any means of remedying this? If so, I shall be extremely obliged, as I am a plate-worker, but have not had much experience in the above line.—Plate Worker.

[56142.]—**Wheatstone Bridge.**—The construction of a Wheatstone bridge, is fully described in Vol. XIX., page 56, but it seems to be only suitable to possessors of long pockets, needing in fact three sets of equivalent known resistances, to determine an unknown one. Is this construction capable of modification, so as to use with the known resistance, against that to be determined? Please avoid algebraical formula.—J. O. M.

[56143.]—**Hermit Crabs.**—What do they feed on? All that I collect, refuse animal food, *i e.*, mussels, sandworms, &c., and soon creep out of their shells and die.—Yesallaw.

[56144.]—**Sea Anemones.**—In May last year I obtained 22 anemones, digging them out of damp sand, in which they were firmly planted, only shewing their corona (which is about 1½in. across) just above the ground. They were mostly securely anchored to small stones or pieces of shell, at a depth of from 3in. to 4in., and very local; also I never found any, if there were any, castings of sandworms in the immediate vicinity. Colour: grey, with sometimes a dash of pale pink, yellow, or purple. What is their name, as I cannot trace them at all in any of my books? They are very hardy, and live in quite foul water, in fact being the only inhabitants of a small aquarium, they remained from May to February in the same water, without any attention, and only two of them died; their bodies were not removed, yet did not seem to affect the health of the remainder.—Yesallaw.

[56145.]—**Wimshurst Machine.**—Some time ago I constructed a Wimshurst electrical machine, from descriptions given in the papers, and with insulated bridges or connections of the opposite electrified sectors on the plate. I always found great difficulty in starting the machine: it was always uncertain, and would never charge itself as stated. I sometimes set it going by charging one conductor, and sometimes some of the sectors. Since then, for the reason that these bridges were not securely fixed, I fastened them in such a way that they were not insulated. This, I was given to understand, was not a material point in the construction. Now I cannot get the machine to act at all. Could you explain the reason of the failure, and tell me how the machine should be started, and whether the conductors should be first electrically connected or not?—E. A. K.

[56146.]—**Spiral Springs.**—Would some obliging reader help me? I need some springs, but find that the steel wire (No. 18) I buy at the ironmonger's, loses its elasticity on compression? I have tried to temper them by heating openly in a fire, and quenching in oil; but they either break, or have no more elasticity than before. Is there any special wire made for springs, or any particular way of tempering them?—David.

[56147.]—**Speeds.**—What is the best system of compensation for maintaining regular speed in winding material from one roller to another, when, for instance, there is 9in. thickness on one roller, and is required to be wound on another, at the same time keeping regular speed in the moving of the material.—Subscriber.

[56148.]—**The Thermal Unit in Relation to Time.**—Is there any method by which the temperature (supposing it to be constant or at its highest point) may be determined from the number of thermal units it parts with in a given time. Is the temperature proportional, both to the heat and to the rate of combination? If so is there any fixed rate of combination for the various elements?—Equivolt.

[56149.]—**Calorimeter.**—What is the best form of calorimeter for measuring the heat of chemical combinations. Practical directions for making such, and if possible, an illustration would greatly oblige. What would be the best and cheapest substitute for mercury in Favre's calorimeter as described in "Ganot's Physics."—Equivolt.

[56150.]—**Time Required.**—I have a vertical water receiver entire length 18ft. diameter 4ft.; it requires 18 minutes to fill the same with a 4in. supply pipe let into the side of receiver 4ft. from the top. How much time is required (out of the 18 minutes) to fill the top 4ft., when the water is above the orifice of supply pipe.—J. B.

[56151.]—**Boring Lathe Heads.**—To "INVICTA."—In No. 1,036, Vol. XL., page 479, Query 55590, you promised to show me through these columns the best way to bore a pair of 2¼in. centre lathe heads (for centres and back-gear spindle) in a 2¼in. centre, single-speed lathe with an ordinary small slide-rest. I have patiently looked for the fulfilment of your promise in this paper since the issue of the above number; but my search has not yet been rewarded. Will you please reply to the above query at your earliest convenience, and oblige?—UNCAS.

[56152.]—**Tempering Steel.**—I have been trying to harden some small tools, but cannot succeed to get them above the blue temper; I heated them in a bright coke fire and quenched in water. I also tried salt-and-water, but with the same result.—UNCAS.

[56153.]—**Test for Oils.**—Can any of our contributors give me a method, or refer me to some reliable work, whereby I can tell when I get pure oils, say of sperm, olive, gallipoli, malaga, southwhale, lard, neatsfoot, animal, mineral, linseed, and cottonseed oils. I do not mind going to some expense to be able to find when the oil is genuine. The s.g. and price paid does not always prove that there has been no doctoring in the oils we buy. I find many users of oil uncertain about the oils they use, and will be glad to see an answer to the above.—W. E. P.

[56154.]—**Working Strain.**—Imagine a piece of annealed ¼in. round shear steel resting on two supports, three inches apart: what weight would it safely bear suspended from the middle? What would be the breaking strain?—F. SEARCH.

[56155.]—**Dry Rot.**—Most of my furniture is ruthlessly attacked by a small insect that bores deep circular holes into nearly all descriptions of wood. Should be thankful for a cure; have tried paraffin; but it seems only effective for a short time. What is the name and the habit of the pests?—F. SEARCH.

[56156.]—**Chemical Action in the Bichromate Battery.**—I shall be glad if any of your scientific contributors will explain as far as possible the chemical actions that take place in a bichromate battery during work, stating what are the salts formed, why the solution becomes black, and if any practical use can be made of refuse liquor.—J. T. S.

[56157.]—**Edison's Electric Pen.**—Would any of your numerous readers inform me as to whether or not T. A. Edison renewed his patent for his electric pen, after that taken out in 1875? I have heard through imperfect sources that Edison was refused a renewal in a law case in which a patent for a telephone was mixed up with it.—R. E. G.

[56158.]—**Injector.**—I have got an injector to fit on a boiler; but I may say that the injector is Vaughan and Stubb's patent. It has only one inlet and one outlet, and has the appearance of a common stop valve; and I can't see how the water can be thrown into the boiler with it. Perhaps some reader that has seen them at work will assist me.—REX.

[56159.]—**Model Engine (Boiler and Boat).**—To "INVICTA."—I have a pair of engines 1⅜in. bore, 2in. stroke. Would you be kind enough to tell me what size the boiler ought to be, and how best to make it? Also, dimensions of boat, and whether I should cut it out of the solid or build it; the engines from bedplate to cylinder covers are 11in. high.—REX.

[56160.]—**Planing Machine.**—I have a hand planing machine with bed 20in. long and 10in. wide. Can I have a quick return made so that I need only to turn the crank handle in one direction? The machine has three spindles, the 1st spindle has a pinion about 1½in. diam., with 15 teeth, which gears into a wheel 7in. with 70 teeth; on 2nd spindle, pinion and wheel are outside the bed, in centre of 2nd spindle is a pinion 2½in. diam., with 24 teeth, gearing with another of same diameter and number of teeth on 3rd spindle, which gears with rack; 3rd spindle is only for the purpose of reaching up to rack. The bearings are conical as in a lathe, and adjusted by lock nuts.—F. SHAKESPEAR, Dresden.

[56161.]—**Telescope.**—What number and kind of lenses are required for an astronomical telescope, magnifying 125, object lens 3½in., focus 4ft. or 4ft. 6in.; and is there any great difficulty in making such a telescope?—F. SHAKESPEAR, Dresden.

[56162.]—**Model Footplates.**—How are the diamond shaped patterns made on the footplates for models of marine and locomotive engines? I have tried casting the plates; but it does not answer, as the plates must bend. Have also tried corroding them with acids to no purpose.—F. SHAKESPEAR, Dresden.

[56163.]—**Mandrel.**—I have bent the nose of my mandrel; can it be set right—if so, how?—F. SHAKESPEAR, Dresden.

[56164.]—**Applegarth Battery.**—Could some practical friend write by post and tell me how to recharge an Applegarth battery for electric bell?—JOHN COLLEY, Salop House, Queen's-road, Aberystwith, Wales.

[56165.]—**Weevils.**—I should like to hear of some remedy for staying the ravages of these. I have them in a bedstead, and have taken it down and soaked the parts with paraffin and afterwards stopped the holes with red lead, but to no purpose. I have them also in some naves which I purpose using for wheels.—SEYMOUR.

[56166.]—**Damp Worskhop.**—Out of a back yard I made a very spacious workshop by putting a flat roof, which rests on four walls. It was made flat for the purpose of storing crates, &c., on the top; but although it has been twice covered with a solution of tar and steel filings, then asphalted, and twice had a ⅞in. coating of Portland cement—it lets through the rain and spoils the tools in the shop. Size of it is 14ft. by 25ft. and the wood used in its construction is planks 14ft. long by 7in. by 3in. covered with ⅞in. floorboards. Would a coating of boiled pitch cure it, if we covered it with planks to prevent sun melting it and walking on it cracking it? Have spent over £4 on it, and now want to cure it in the cheapest way possible, as it is only a temporary erection. It has a fall of 4in. with rain channel on the long side.—TRICYCLE MAKER.

[56167.]—**Developer.**—As the photographic season is now rapidly advancing, can I get any assistance? I have been using Wratten and Wainwright's developer (as per last almanack)—two grains pyro, and three drops each diluted ammonia and bromide. Is it a very slow developer?—as I find after the image is out, and the detail, &c., fairly discernible, the negative appears weak and covered by a greyish mist after fixing, although sharp. I do not think they are over exposed, as they are rather long in coming up. How long should a C.D.V. take to develop by the formulæ? I forgot to say I use Fry's plates.—JAY PEA.

[55168.]—**Electro-Plating.**—I do a little electro-silver plating, but am much bothered by the silver anode becoming discoloured, sometimes with a brownish film, and at other times with a thick, bluish-white coating, and I find that when either of these takes place, that the deposit ceases; it seems only by a fluke that the anode will occasionally work with a clean surface, and when it does, the deposit is all right. I have tried different battery-powers, and have varied the strength of solution (cyanide of silver), and sizes of anodes and cathodes. I have done a lot of electro-gilding, and have very little difficulty with that. Will some of "ours" put me right?—ARGENT.

[56169.]—**Spectacle Lenses.**—Can any one tell me the meaning of the formula, prescribed by the oculist? For instance, I have a pair of convex glasses, formula + 1 D; another of my family has − 4 D, and − 1·5 D. Do these figures relate to absolute measurements, or to some artificial scale? One would like to be able to select the proper glasses for oneself. Also is there any real advantage, and if so, what, in having pebbles (so called) instead of glass lenses?—BAL-NA-CILLE.

[56170.]—**Municipal.**—I should be glad if some one would give me his opinion, whether for general examining work, and also delicate work, a binocular, or single microscope would be preferable. Also please recommend me a good work on practical microscopy for beginners.—H. T. BARNETT.

[56171.]—**Gas-Engine.**—To "INVICTA," FROM "GASSY."—Thanks very much for your replies to my two queries. I quite understand the rule for air compression. As regards the gas-engine, I want it to replace a single cylinder, 4½in. bore by 6in. stroke, working at 60lb. Would you recommend a vertical trunk engine, single acting—if so, what dimensions?—or the ordinary inverted single cylinder, like Clerk's; if so, what size? I have no idea of what size the air-pump should be, the gas pressure, or what valve arrangement, and firing gear is to be used. Can you kindly help?—GASSY.

[56172.]—**Locomotive Mechanics.**—Supposing that a loco. engine's eccentric rod had not been properly adjusted, and as a consequence she had a lop-sided sort of a beat, and supposing that the forward gear-rod wanted shortening to put it right, would it be necessary to lengthen the back-gear rod?—YOUNG HAND

[56173.]—**New Battery.**—Can any reader tell me how to make the new cell, invented by Dr. Pabst (Germany)? I believe it is an iron cell, with wrought-iron and carbon dipping in a solution of ferric chloride.—F. Q.

[56174.]—**Dioscope.**—How are these made? They are to enable a person to see what is going on (at an entertainment, &c.) from a distance, by means of an objective lens and electricity.—A.

[56175.]—**Books on Herbal Medicine.**—Can any one give me information as to the most recent and best works on herbal medicine? Not mere family guides, but works that will enable one to thoroughly study and master the subject.—W. M.

[56176.]—**Patent Annealed Iron.**—Has any reader of the "E.M." had any experience with the new process of annealing chill and other iron castings, and how they make their chill, and what kind of castings they make?—MELBOURNE.

[56177.]—**Earthenware.**—Mr. S. Arlidge, in the "E.M." of Feb. 6th, referred to my query on the above subject, but he does not say what ingredients are used in giving the white colour to earthenware, before putting on the lead for glazing. In making black ware, we use black manganese, but I want to make white ware as well. Any information that Mr. Arlidge, or any others can give on this subject, will be highly appreciated by—J. HAYDOCK, Mon.

[56178.]—**Gum Juniper.**—Will any of your readers kindly inform me how to dissolve gum juniper—I have tried several ways but failed, and oblige?—KOILA.

[56179.]—**Bort.**—Will "Z. Y. X." be so kind as to state if bort, carbonado or carbonate, can be manufactured, or is it a natural production?—CARBON.

[56180.]—**Martini-Henry Rifle.**—Will "Armourer" be so good as to explain the proper way to take the breech action of a Martini-Henry rifle to pieces and replace same, and what is the lubricant used. it appears to be some thicker substance than oil.—ANOTHER RIFLEMAN.

[56181.]—**Cheap Achromatic Condenser.**—To MR. NELSON.—I should be glad to make a condenser, as described by you, if you will kindly inform me what focus the two lenses should be, as I presume they should bear some proportion to each other. The hole in the stage of my old upright microscope is ⅝in. in diameter, and there is only 1¼in. space between the top edge of the mirror (when inclined) and the upper surface of the stage. I have tried single lenses as condensers, but without advantage.—NOVICE.

[56182.]—**Sweet Making.**—Will some kind reader give me information how to make sweets (brown sugar goods) quantity of water per pound of sugar, and how long to boil, or can any book be got on the subject?—NOVICE.

[56183.]—**Force and Motion.**—What is the answer to the following question?—Given a rope with a horse at each end. The horses are started in opposite directions Is the pull on the rope that of two horses, or of one? Similarly in a steam-engine, is the strain on the cylinder cover, the same as that on the piston, or more?—T. P. L.

[56184.]—**Transfer Fluid for Engravings.**—Would any correspondent tell me if there is any chemical that would produce an impression or copy from engravings?—T. P.

[56185.]—**Astro. O.G.'s.**—Would anyone give me particulars respecting the making of fluid lenses, and how the old astronomers did without achromatic lenses?—Cassini and others of his time.—T, P.

[56186.]—**Gum for Micro. Slides.**—I should feel obliged if one of our kind readers would give me a recipe for making gum for attaching labels to microscope slides—such as is used on postage and other adhesive stamps?—A. B.

[56187.]—**To Mr. Bottone.**—Would you kindly help me with the following?—I have made a motor with one of Jones' laminated armatures, 1½in. diameter and 4in. long. I first wound it with 4oz. of No. 22 s.c. copper wire on armature, and 1½lb. of No. 16 c.c. on magnets; but, with the idea of improving it, I rewound it with 6oz. of No. 22 s.c., and 2lb. 9oz. of No. 18 c.c.; but on trying it with two quart Bunsens I got less power than I did at first with the same cells. Would you kindly say if the wire I have on just now will be right with more battery power? If so, how many quart bichromates shall I use, and what power may I expect?—LOANHEAD.

[56188.]—**Pump.**—Would some kind reader conversant with brickworks kindly give short description, with small sketch, of a simple pump or other means for lifting—about 5ft. or 6ft. of a lift—water out of brick clay holes?—something that would lift a considerable quantity at a time for manual power.—T. PLUNKETT.

[56189.]—**Brickmaking Books.**—Wanted, names of a few thoroughly practical works on above, and which would give description, with plans and dimensions, of best sort of up and down draught kilns.—THOMAS PLUNKETT.

[56190.]—**Clark's Gas Lamps.**—Can any reader inform me whether those powerful smoke-consuming gas-lamps, which are fixed at the Langham Hotel, are made on a small scale?—W. C.

[56191.]—**Electrotyping.**—Can any of our readers inform me of the latest method of copying wood blocks, or refer me to work (recent) on above, the cost of necessary plant, and where to be bought?—ELECTRO.

[56192.]—**Mineral.**—Can any reader kindly inform me of the name of the above from the following description?—Glistening white, under microscope like minute transparent sand; heated slightly light brown, intense heat nearly black; insoluble in cold water; from boiling water white opaque gelatinous deposit; soluble in sulphuric acid; carbonate of ammonia turns solution brown; ferrocyanide of potassium blue, with white deposit at bottom.—W. G.

[56193.]—**Eccentric and Oval Cutting Chuck.**—Will some correspondent kindly either furnish us with a working drawing, or say where it is to be met with, as I wish to make one?—H. G. B.

[56194.]—**Lady's Colonial Outfit.**—Can any reader give reliable information as to a useful outfit for a lady going to the country parts of New Zealand? and also what size of packages are more convenient for luggage, and any hints about the voyage? In fact, any useful information on the subject will oblige an—OLD READER.

[56195.]—**Consumption of Coal.**—Would any of our readers kindly inform me approximately the quantity of coal consumed per day of 24 hours upon some of the large Atlantic-going mail steamers, such as the *Alaska*, *Oregon*, *Nevada*, &c.?—J. L.

[56196.]—**Gas Holder.**—I have a job to put some new sheets in an old gas-holder; I have heard some special packing is required for the joints. Will someone say what is the best thing to make them gas-tight when riveted?—OLD SUBSCRIBER.

[56197.]—**Rusty Water.**—Some months ago we laid about 1,000ft. of black iron tube from a high-level well across some fields to a dwelling-house some 30ft. lower. Up to the present moment the water has been so rusty that it is quite unfit for use. Can any of our readers suggest a remedy that will not unfit the passing through pipes for drinking purposes?—F. D. A.

[56198.]—**Speed of Pump.**—What is the quickest speed at which I can drive an ordinary 3in. brass barrel bucket forcing pump 8in. stroke? Would it be possible to drive such at 120 or 180 strokes per minute? What quantity of water would be delivered at each of these speeds, and what power would be required to lift and force a height of 50ft. (suction included) at each of these speeds? Would indiarubber valves be better than leather at such speeds?—J. D. A.

[56199.]—**Nickel.**—Is this much harder than copper, and what is the relative hardness of nickel bronze and copper, and what are the proportions of the alloy called nickel bronze? Can the alloy be made harder or softer at pleasure by using different proportions, and if so what different proportions? If these are secrets of trade, I of course do not expect a reply.—Z. Y. X.

[56200.]—**What is a Diamond Carat?**—Per Mr. Emanuel's book, a carat is 4 grains, therefore a diamond of 2¾ carats ought to weigh 11 grains. I sent one out of a ring to a manufacturing jeweller, asking him to say how many carats and how many grains. His written reply was—2¾ carats, 11 grains; thus he agrees with Emanuel. But, on weighing the diamond in a pair of chemical scales, it is found only to weigh 8.70 grains. My deduction is that a diamond carat is only 3·16 or 3 1-6 grains, and not 4. What is the truth, and what is the explanation? I do not enter in the gold carat, where the term has a different meaning—viz., a something which has so many parts of pure gold out of each 24 of actual weight of the article; thus, 6 silver and 18 gold is 18 carat fine, and absolutely pure gold is 24 carat fine.—Z. Y. X.

[56201.]—**Fixing Battery Plates.**—I am making a double-cell bichromate battery arranged as follows:—The outer cells are square, and are placed in a rack which has two uprights at each end, between which a counterpoised board slides; to this board the plates are fixed by brass clips screwed down to it. This answers well enough for the carbons, but the zincs being heavy slip from between the jaws of the clips. Will any reader kindly inform me of a method of fixing the zincs so that they may be readily removed for amalgamation, &c.? Please do not refer me to back numbers, as I am a new subscriber.—MIKROS.

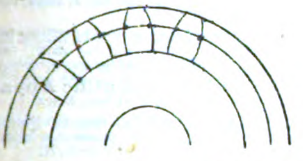
[56202.]—**Clock Gongs.**—Would some correspondent kindly tell, me through the columns of "Ours," how to make clock gongs, the kind of steel they are made of, and how to harden and temper them?—CHIME CLOCK.

[56203.]—**Chemical Affinity.**—Will some chemical reader kindly publish in "Ours" (of course with the Editor's permission) a reliable table of affinity, embracing that of the principal acids for the various bases? Such a table would, I opine, be of the greatest use to beginners in the science.—EQUIVOLT.

[56204.]—**Calorimetry.**—Would it be too presumptuous on my part to ask "Sigma," S. Bottone, or others, to give the chief results of Favre's and Silberman's experiments upon the heat of chemical combustion and combination, such as are given in Mr. Sprague's "Electricity," or can they recommend a cheap book on the subject?—EQUIVOLT.

[56205.]—**Tennis Court.**—Will anyone kindly give instructions for making a cinder court for lawn-tennis; The intended site is part of a grass field; should the turf which is taken up, go to make a bank round the court? How is the ground made truly level? What are the correct measurements for court? Information will much oblige.—CHROMIO.

[56206.]—**Teeth of Wheels.**—Will someone of "ours" kindly give me particulars for striking out teeth



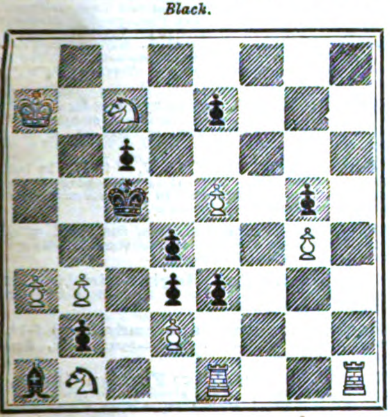
with one sweep, as per sketch. Prof. Willis invented an instrument for the centres and radius for different-sized wheels (I don't mean the odontograph, with two radii)—do any of "ours" know it?—ATHOS.

# CHESS.

**ALL Communications for this department must be addressed to J. PIERCE, Llandwrog, Carnarvon.**

**PROBLEM DCCCCXXXI.**—By H. F. L. MEYER.

*Black.*



*White.* [10+9

White to play and mate in four moves.

SOLUTION TO 929.

| *White.* | *Black.* |
|---|---|
| 1. Q-Q Kt 7 | 1. Anything |
| 2. Q, B or Kt mates. | |

(Seven variations.)

## NOTICES TO CORRESPONDENTS.

CORRECT solutions to 929, from Rev. W. Anderson (Old Romney), H. Culmer, J. E. Piper, C. Meiklejohn.

To 928 by H. Culmer.

C. MEIKLEJOHN.—You have overlooked that in 928, after 2. Q-Q 2 Black can play Kt-Q Kt 3, thus avoiding mate.

GAME received from F. A. Vincent. Tourney Problem from "Chess Struck."

"E. M." Tourney game between W. Nash (White) and J. Clothier (Black).

(King's Bishop Gambit.)

1. P-K 4, P-K 4 / 2. P-K B 4, P takes P / 3. B-B 4, P-K B 4 (*a*) / 4. Q-K 2, Q-R 5 (ch) / 5. K-Q sq, P takes P / 6. Q takes P (ch), K-Q sq (*b*) / 7. Kt-K B 3, Kt-K B 3 / 8. Q-B 5, Q-R 4 / 9. Q takes B P, P-Q 3 / 10. Kt-B 3, Q Kt-Q 2 / 11. P-Q 4 (*c*), Kt-Kt 3 / 12. B-Kt 3, B-Kt 5 / 13. R-K sq, B-K 2 / 14. Kt-K 4 (*d*), K Kt-Q 4 / 15. Q-Kt 3 (*e*), B-R 5 / 16. Q takes B (ch), Q takes Q / 17. B-Kt 5 (ch), Q takes B / 18. Kt takes Q, K-Q 2 / 19. P-Q R 4 (*f*), P-Q R 4 / 20. K-Q 2, B takes Kt (*g*) / 21. P takes B, P-K R 3 / 22. Kt-K 6, P-K Kt 4 / 23. P-Q B 4, Kt-K B 3 / 24. R-K 2, Q R-K sq / 25. Q R-K sq, P-Q B 3 / 26. K-B 3, Kt-Q B sq (*h*) / 27. B-B 2 (*i*), K R-Kt sq / 28. B-B 5, R-Q sq (*k*) / 29. Kt takes P (ch), K-B 2 / 30. Kt-K 6 (ch), K-Kt sq / 31. Kt takes R, R takes Kt / 32. B takes Kt, K takes B / 33. R-K 6, Kt-Kt sq (*l*) / 34. R-K 8, resigns.

(*a*) This defence is now considered superior to P-Q 4. Mr. Bird is fond of Q-R 5 (ch) at once, and with good reason, judging by results.

(*b*) Cook gives B-K 2 as best.

(*c*) We prefer B-K 2 followed by Kt-K Kt 5.

(*d*) B-K 3 and then K-Q 2 to free the Kt, looks more developing.

(*e*) The only move.

(*f*) With the view to gain a piece.

(*g*) P-K R 3 seems better.

(*h*) On account of P-Q B 5.

(*i*) A good move, of which Black fails to see the force. R-K 2 meets it best.

(*k*) Now if 28 $\frac{\qquad}{\text{R-K 2}}$ 29 Kt-B 5 (ch) &c.

(*l*) This saves Kt and P, but game was already lost.

# ANSWERS TO CORRESPONDENTS

⁂ *All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, 332, *Strand, W.C.*

## HINTS TO CORRESPONDENTS.

**1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put** titles to queries, and when answering queries put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

**⁂ Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.**

## A NEW VOLUME.

NUMBER 1041 was the first of Vol. XLI. Readers willing to oblige us by recommending "Ours" to new subscribers should do so now, when a new volume has just commenced. The index to Vol. XL. is published this week, and cases and bound volumes will be on sale shortly. Readers desirous of making up their sets for binding the past volume are recommended to do so at once, as the back numbers soon run out of print.

The following are the initials, &c., of letters to hand up to Wednesday evening, March 18, and unacknowledged elsewhere:—

PALL MALL ELECTRIC ASSOCIATION.—R. E. Quinn.—W. Matthew.—F. L. Moore.—Otto Co.—J. Manford.—R. Hannen.—C. H.—The Optical Bricklayer.—C J. K., Ventnor.—Samuel Shaw.—Millwright.—E. H. J.—C. L. Tweedale.—B.Sc., Plymouth.—E. M.—Wade.—Jack.—A Many Years' Subscriber.—J. Gayler.—T. R. Allinson.—M.I.C.E.—A Fellow of the Royal Astronomical Society.—E. J. S.—J. H.

G. O. W. (Can only afford so much space and so many engravings to replies, not to questions asking whether proportions, &c., are good. Besides we have had a great deal about dynamos lately.)—STERO. (What is it you mean by "French bronze"? Look through the index issued with this number, and see if there is not some reference to it. "Where to get materials" is answered by "At any dealer's." Such a question is against the rules.)—F. S. S. A. (Gum arabic dissolved in water. See the indices, or Richmond's "Grammar of Lithography," published by Wyman and Sons. Transfer paper is prepared by coating any good paper with gelatine, starch, or gum, or mixtures of the three, the object being to interpose a soluble film between the writing ink and the surface of the paper. It is always best to purchase the inks and papers required when working on a small scale.)—VULCANITE. (The ink is dissolved in soft water or alcohol according to its nature, and glycerine or treacle added—sometimes both. For aniline violet, dissolve 90 grains in 1oz. of rain or distilled water, and add a little glycerine. Several recipes in back volumes.)—W. W. (Bellows camera in No. 894, or p. 380, No. 953.)—A COLLIERY SMITH. (We do not know of any useful liquid for welding steel. Borax is generally sufficient in the hands of expert smiths; but some fuse 10 parts of borax with one of sal-ammoniac until all spume has disappeared, and then pour out, and when cold pound into powder.)—INK. (Grind up any suitable pigment with gum tragacanth in solution, and mould under high pressure, or treat the same as pigments for making cakes of water colours. That is, grind up with isinglass size and thin gum water; but the pressure is indispensable.)—J. M. B. (Free ventilation is the best way of removing the smell of fresh paint; but some use a handful of hay in a pail of water, and others close up all air-holes, and put in a vessel containing lighted charcoal, on which they throw a handful or two of juniper berries.)—AMATEUR. (Yes, they are tuned to equal temperament. The best plan is to get a set and tune others to it. The scale in G is just the same as in C, except that it has F sharp instead of F natural. In factories they have a tuning bellows, on the exhaust plan generally, and fixing the standard reed over one hole tune the others to it. They require very little afterwards when placed in instrument.)—WARMINSTER. (We have no time for problem solving, and we are afraid there are not many of our readers who could tell you "at what velocity must a turbine run to generate electricity sufficient for a town of 6,000 inhabitants at a distance of three miles." Do you know of a turbine which generates electricity. 2. We do not know, but the makers can tell you. 3. As to the cost of wire, see the lists, wherein you will find the prices per mile for the different sizes. You have forgotten the latter item.)—PENWITH. (You will find a very good pocket battery described on p. 119, No. 1019; but see the indices.)—ECONOMY. (We do not understand how any one is to tell you how to make the battery or accumulator, the only description of which is that it is in an ebonite case 4in. by 5in., and ¾in. thick. See previous answer. It is probably a chloride of silver cell.)—C. H. (Given in all works on navigation; in the *Nautical Almanac*, and in back volumes. 2. What "astronomical clock" do you mean?)—T. B. (You will find an improved baking powder on p. 229, Vol. XXX., and several recipes in Nos. 739, 740. A good recipe is 1lb. bicarbonate of soda, ½lb. of tartaric acid, and ¾lb. of ground rice.)—NIX. (There is no book of the kind; but you can obtain suitable apparatus of any dentist's furnisher. See the articles on the indiarubber and guttapercha industries in Vols. XXXI. and XXXII. These were also published in a cheap form by the Society of Arts. You can ascertain whether still in stock by applying to Messrs. Bell and Sons, York-street, Covent-garden, W.C.)—A SUBSCRIBER, F.G. (See the indices for medical coils, shocking coils. Look in last week's number, for instance.)—CONSTRUCTION. (Look on p. 475, No. 1,036. Oxide of copper, zinc, and a solution of caustic soda.)—D. D. (Let them read up the subject of Flight in back volumes. How would they store the electricity which is to supplement the man's motive power? Do they think they can put it into a balloon like so much gas?)—MUSICIAN. (It is something loose; from what you say some part of the swell action—very likely the wire spring. When you hear the "jarring," try touching all likely loose parts.)—IN THE DARK. (If the connections are all right, possibly it is the zincs which are at fault, especially as they appear eaten into holes; they should be amalgamated after each time of working—that is, if you use the light for any considerable time. See pp. 110, 174, 193, 217, Vol. XXXIX., for some useful information.)—J. O. M. (It would occupy too much space to explain fully; for that you must see the textbooks. But the effect of a fault is to decrease the resistance of the circuit and to weaken the current received at the distant station. Calculations will indicate the whereabouts. A broken line is found by asking each station in turn to put the line to earth, until one is unable to deflect the needle of a galvanometer: the break is between that and the previous station. The distance is found by the aid of the "bridge.")—ZENO. (You can obtain all particulars about the Whitworth Scholarships from the secretary of the Science and Art Department, South Kensington. The guide is 6d., we think; but there is a book of the kind you mention, published, we believe, by John or Abel Heywood, Manchester, which gives much useful information.)—HEALTH. (We believe Macmillan and Co., Bedford-street, W.C., publish such a work.)—B. B. (Both. The pores of the charcoal contain oxygen which burns up the organic matter. That is why it is necessary to clean the charcoal occasionally, and leave it dry at frequent intervals.)—E. F. J. H., Manchester. (You are just about the right age to enter any branch of the engineering profession. The usual thing is to be articled for a term, unless you wish to go through the shops and become proficient as a mechanical engineer. Then it is usual to enter as a gentleman apprentice. We do not know which branch has most openings, and cannot advise in such a matter.)—J. G. BRISTOL. (We have given full particulars of the New Patents Act on pp. 25, 376, Vol. XXXVIII. It is not necessary to employ an agent, but it is advisable. The difference in the charges is an indication of the value the agent puts upon his services. The stamp payable on an application is £1.)—J. E. (Two methods of making dark slides in No. 979. For shutters see indices.)—W. FREEMAN. (See the index published with this number, and back volumes for all sorts of methods for making enlargements.)—TRICYCLE. (Put yourself into communication with Mr. Shipton, Secretary of the Cyclists' Touring Club, 139, Fleet-street, E.C. 2. If there is only one bookseller, surely there is a bookstall at the railway-station, and you can get any paper there almost as soon as it is published.)—TRICYCLE FRONT WHEEL. (The rubber is too large; but why not bind it on?)—RAGOSINE OIL. (It is a petroleum, and is composed of hydrogen and carbon.)—ENQUIRER. (You should not go unless you have money to start in business, or can afford to wait until you make a connection. Work of the kind is highly paid, but then there is so little of it to do.)—READER OF "E.M." (Why not have mentioned the page? It is Part II. of Miller's "Chemistry" that is meant, price 21s. The apparatus is simply an ordinary sheet-iron furnace with a chimney and legs. An iron tube passes through the centre horizontally, and so through the middle of the fire. This tube is filled with iron borings or turnings, which, when red-hot, decompose steam, absorb oxygen, and leave the hydrogen free. The usual apparatus is illustrated in many textbooks.)—TRUKH-SUNKER. (Surely it would depend on the length of the holes or tunnels; but at any rate, such a query is of no interest to our readers. We do not know of a work giving such information.)—P. WARD. (A reply by post sent as asked has been returned through the Dead Letter Office marked "insufficient address.")—XEMA. (It is a question for a jury; on your own statement you are undoubtedly "A.'s" agent, and entitled to a commission: but then some people have such a remarkable facility of becoming agents to people who have never authorised and do not want their services.)

**Dr. Carter Moffat's Ammoniaphone** (Harness' Patent). This excellent invention for strengthening and improving the voice, and for curing ASTHMA, BRONCHITIS, and all pulmonary affections, of which a full description, illustrated by a sectional view of the instrument, appeared in the ENGLISH MECHANIC for Dec. 26th, has been secured by the Medical Battery Co., 205, Regent-street, London, W. Its efficacy is vouched for by the highest medical, scientific, and social authorities, and Dr. Carter Moffat attends daily at 205, Regent-street, London, W., to demonstrate its extraordinary utility. Residents at a distance should write for "The History of the Ammoniaphone," sent post free to any address. Dr. Carter Moffat's Ammoniaphone will be sent post free to any address on receipt of P.O.O. or cheque value 21s., and payable to C. B. HARNESS, The Medical Battery Co., 205, Regent-street, London, W.—[ADVT.]

An **Orrery**, showing telescopic view of principal planets and their satellites revolving round the sun, the moon and its changes, several other views, including the Thames Tunnel and the Bay of Naples; two microscopes, mahogany tripod stand, lamp, &c.; the whole suitable for a street exhibitor. Cost £30; to be sold very cheap.—Apply to A. Bond, 7, R Block, Peabody-buildings, Blackfriars road.

Try one of my hollow-ground **Razors**, warranted. Will be exchanged if not approved of. Post free, 1s. 4d. The only real razor maker in London. Two prizes awarded for manufacture and excellence of workmanship. German Razor Hones, post free, 1s. 2d. Razor Strops, army or cushion, post free, 1s. 3d. Established 1804.—Mundy, Cutler, Greenwich, S.E.

**Astronomical Observatory**, complete, with instruments, books, and comprising 6in. diameter equatorial, driving clock, circles, complete; transit with 2 circles, sidereal clock; all above now in adjustment, and in good working order. A bargain for cash, or deferred payment. A capital opportunity for starting an astronomical observing society.—Mr. Knowles, 36, Fountain-street, Manchester.

Twisting, Reeding, and Fluting **Lathe**. While inventing the spiral lathe my aim has been to make it in as few parts, to lessen the friction, and make it as cheap as possible, so that it may be within the reach of every woodturner. I have done small pillars of stone, coal, and clay. Will some one make an offer for it?—Scott.

Amateurs and the trade supplied with **Dynamo** Castings and every description of wire for electrical purposes at lowest possible rate. Dynamo Castings machined and fitted ready for winding. Dynamo machines repaired.—Ashby.

Gramme **Dynamo Machines**, sound and well made, suitable for lighting shops, &c. Expressly made for long running; long bearings, massive fields; 100 candle power, £6 10s.—A. Ashby, 184, King's-road, Chelsea.

Good four-inch Spark **Coil** of the most approved construction, compact, and working with moderate power, patent contact breaker, discharging points upon glass pillars.—Apply to Cambrian, 6, Castle-terrace, Haverfordwest, Pembrokeshire.

"**English Mechanics**," Vols. XI. to XXIII., bound, for sale, 2s. 6d. per volume.—Pip, 46, Union-road, Clapham.

12 by 10 inches **Opal Painting** from any photo or negative, 10s.—Simmons, Artist, Galway.

**Induction Coil**, 1in. spark, discharging pillars, commutator, and condenser, price 50s.—Williamson, 61, Derby-street, Bolton.

**Medical Coil**, large, with bell and switch, mahogany base, price 35s.—Williamson, 61, Derby-street, Bolton.

**Telescope** (day or night), on claw pillar stand, all movements mounted in brass, 1⅞ achromatic object glass, price 35s.—Williamson, 61, Derby street, Bolton.

Half-horse **Horizontal Engine**, a bargain, 35s. Photo, 3 stamps.—M., 14, Church-street, Oldbury.

**Boiler**, three-horse horizontal, £4 10s. Photo, three stamps. Blacksmith's Bellows, 12s.—M., 14, Church-street, Oldbury.

**Electro-Motor**, about half-horse, new, £4 or exchange. Launch engine wanted.—Ellis, 2, Prince's-street, Doncaster.

"**English Mechanic**," eight Vols., 1881 to 1884 inclusive, unbound, 15s., or exchange.—Principal, 1, Cambray, Cheltenham.

**Tricycles.**—Singer's "Apollo," "Traveller," and "Telescopic," quite new and unused; giving up agency. Five shillings in the pound off list.—Falkner, Ironmonger, Southport.

**Mechanics' Injuries.**—Bruises, Burns, Sores speedily cured. Our Rosemary Ointment, 7d. stamps.—Edward Hewitt, Heaviley, Stockport.

**100ft. Glass**, cut to size, packed, delivered to rail, 13s. 6d. Picture quality, 17s. 6d.—Holmes, 149, Essex-road.

Serrin **Arc Lamps** for sale, in good order, £3 each. Launch Engine and Boiler for sale, £60, all complete, with shafting and propeller, &c.—R. Ruffett, 86, Richmond Villas, Huntingdon-road, Cambridge.

**Micrometer Gauges** for accurate measurements; will measure by the 1,000th part of an inch.—Jeamy and Son.

Circular **Stocks and Dies**, for cutting a full thread at once running down. Lists, 1 stamp.—Jeamy.

**Stocks and Dies**, warranted quality, Whitworth and ordinary angular patterns.—Jeamy and Son, North-street, Stafford.

Thoroughly good Scientific **Instrument Maker** can hear of £1 or £2 worth work.—Apply, G. M., 39, Church-lane, Hull.

**Launch Engines and Lathes**, the best value. Please state requirements.—John Middleton, 16, Hope-street, Glasgow.

**Lathe**, 7in. back-geared, compound slide-rest, overhead, treadle, £8 10s.—John Middleton, 16, Hope-street, Glasgow.

New **Circular Saw**, Fret Saw, groover, doweller, for cabinetmakers and joiners. Will cut 3ft. 8in. off 1in. mahogany after you take your foot off the treadle.—Britannia Co.

**Builders' Exhibition.**—The new Treadle Saw cannot be shown owing to an accident. It will shortly be at work in London.—Britannia Co., Patentees and Sole Makers, Colchester.

Pair **Mixed-Gas Jets**, cog-turners, 28s. Pair all bright, 32s. Safety Jet, 10s.—Amateur.

New Mahogany **Biunial**, tin lined, rack pinion, achromatic fronts, 4in. condensers, £7.—Amateur.

Everlasting **Retort**, 7s. 6d. Stout Brazed Retort, 6s. 6d. Six-way Dissolver, 15s. All new.—Amateur.

Pair **Gas Bags**, 42 by 36 by 24, used a few times, 42s. each. Lime Box, 3s.—Amateur.

One of Hughes' large **Objectives**, cost 95s.; price 30s. Several smaller ones cheap.—Amateur.

Triple **Lantern**, original design, nearly new, with every accessory, £25.—Full particulars from Amateur.

Pair 4-inch **Condensers**, 28s. Lantern, with rack pinion, Newton's 3-wick lamp, 58s.—Amateur.

All the **Above** equal new and are hardly soiled. Cash returned if not approved of.—Amateur.

**No Reply** indicates sold.—AMATEUR, Ernest Cottage, Peyton-place, Greenwich. Late manipulator to Rev. C. Spurgeon.

Builder's **Quick Hoist**, by Powis, cost £30, sell for £10. Moved for improvements. Seen working at D. Noakes and Son, Billingsgate Wharf, Greenwich.

For Sale.—Double acting **Hot Air Engine**, ½ h.-p.—Apply, J. A., 46, Frith street, Soho, W.

**Chemical Apparatus.**—New Catalogue of 90 pages, with over 500 illustrations, 3d. post free.—Hume, Lothian-street, Edinburgh.

Working **Metal Patterns**, for making patent differential chain pulley blocks, on sale.—Weston, 5, Atkinson-street, Stockton on-Tees.

"**English Mechanic**," Vols. V., VI., VII., bound, 12s. 6d.—W. H. Wilson, Ferry Boat-lane, South Town, Great Yarmouth.

**Dynamo**, 1½ armature, coil, 2 16c. Edison's, price 30s., carriage paid.—12, Renfrow road, Lambeth.

~~**Rubber Stamps.**—Recipe for stamps and all requisites, sent post free 6d.—F. P., Shadwell, Leeds.~~

**Selenites**, red, yellow, blue, and green, 1s., post free.—G. Scoram and Co., Bradford.

**Micrometers**, divided into hundreds and thousands of an inch; also millimeters, 3s. 1d., post free.—Scoram and Co., Opticians.

**Sensitised Paper.**—Best thick high glaze, 9d. sheet; 13s. quire.—Scoram and Co., Bradford.

**Camera Finder**, for keeping the object in the centre of the field, 7s. 9d., post free.—Scoram and Co., Bradford.

**Canary Medium**, perfectly safe for all dry plates.—Scoram and Co., Bradford.

How to Make **Electric Soluble Ink Pellets**, genuine recipe, post free, 13d.—G. Marquis, Allhallowgate, Ripon.

**Electric Jewel Lights**, with pocket battery and one jewel, 21s.; with 2 for ears, 35s.—Baughan, Charlbury.

**Electric Bell Fittings** and Sundries.—Bells complete, bell magnets, pushes, batteries, electric jewel lamps, toy induction coils, &c. Job lot to clear. No reasonable cash offer refused. Send for list.—H. F., Charlbury, Oxon.

Model **Engine Castings.**—Horizontal, Locomotive, Vertical, Beam, and Marine. List, stamp.—Wood, Dalley-street, Broughton, Manchester.

Launch **Gas Engine**, generates its own gas. Complete Castings, 50s. Drawing, 5s. Litho, 3 stamps.—A. Dorrington, West Gorton, Manchester.

**Working Plan and Details** of Boat for the above Engine, 5s.—A. Dorrington, West Gorton, Manchester.

The Amateur's **Gas Engine**. Complete Castings, 42s. Working Drawing, 5s. Litho, 3 stamps.—A. Dorrington, West Gorton, Manchester.

**Tricycle Gas Engine.**—I will design and supply materials should there be a demand.—A. Dorrington, West Gorton, Manchester.

Half horse-power Horizontal **Engine Castings**, ports in cylinder, 12s. 6d. Drawing, 18 stamps. Litho, 2 stamps.—A. Dorrington, West Gorton, Manchester.

The Amateur's **Drilling Machine**. Castings, 3s. 9d. Forgings, 3s. Drawing, 8 stamps.—A. Dorrington, West Gorton, Manchester.

No. 2 **Drill**, self-acting feed motion. Castings, 7s. 6d. Forgings, 5s. Drawing, 18 stamps.—A. Dorrington, West Gorton, Manchester.

3 or 4-jaw **Chuck Castings**, 3s. Forgings, 1s. 2d. Drawing, 6 stamps.—A. Dorrington, West Gorton, Manchester.

4½in. **Fan Castings**, 3s. 6d. per set. Drawing, 4 stamps.—A. Dorrington, West Gorton, Manchester.

**Working Plans**, Lines, and Details for Canoes, Skiffs, and Launches. State requirements.—A. Dorrington, West Gorton, Manchester.

**List** of Castings and Working Drawings, 1 stamp.—A. Dorrington, West Gorton, Manchester.

**Incandescent Carbon Lamps**, low resistance, 3s. each; Fairy Lamps, 3s. 6d.; Platinum Lamps, 1s. 3d., post free.—Todd, 14, Wentworth-road, Manor Park, Essex.

**Incandescent Lamp Holders**, new pattern, best in the trade, 12s. dozen; sample, post free, 1s. 3d.—Todd, as above.

**Leclanche Cells** (to make up).—Glass jar, porous Pot, Capped Carbon, Amalgamated Zinc. No. 1, 1s. 5d.; No. 2, 1s. 2d.; No. 4, 1s. per set, complete. Sal Ammoniac, Manganese, cheap.—Thompson, Dowsing, and Rew, Manufacturers, 4, Queen Victoria-street, London, E.C.

**Locomotive Photographs**, Midland, L. and N.W., and principal railways. List and specimen, 5 stamps.—F. Moore, 1, Naas-road, Wood Green, N.

**H. Jones** begs to state that the armature Chaster tried in his motor was not the one suggested, but my patent H Armature.

**Formulas Worked Out** for winding Dynamos and motors from 10 c.-p. to 500 c.-p., 14 stamps. Drawings and Diagrams from 5s.—H. Jones.

**Dynamos**, patent improvements, No. 2,122. 70 c.-p. machines, £5. 32 volts, 7 ampères.—H. Jones.

**Dynamos**, best small machines in the trade, and cheapest double-covered Wires to 20 gauge, 1s. 8d. lb.—H. Jones.

**Motor Castings** (model 5-light dynamo), laminated armature, 20 per cent. better than solid. 3s. a set.—H. Jones.

**Dynamos** for Home Lighting.—5 lights, or arc of 500 c.-p. Price £6 10s., approval. Warranted.

**Dynamo Castings**, with laminated armatures, 8 c.-p., 5s.; 16, 5s. 6d.; 20, 6s. 6d.; 30, 7s. each.—H. Jones.

**Dynamo**, laminated armatures, no heating, ventilating; 70 c.-p., 16s. a set; finished, £5. Warranted.—H. Jones.

**Dynamo Machines Repaired.** 100 c.-p., 9s. Motors, with wire, 5s. 6d.—H. Jones, 48, High-street, Lambeth, S.E.

One or two good 9in. **Mirrors and Flats.**—S. Cooper, Charminster, Dorchester.

**Universal Trade and Amateur Supply.**—Lecture requisites; light, heat, air, water, geology, engineering, chemistry, photography, &c. Wholesale and export.—Caplatzi.

**As Before**, with large additions from Optical, Photographic, Chemical Stocks, Balances, Prisms, Spectroscopes, Telescopes, Stands, O.G.'s, Eyepieces.

Model **Steam and Electric Engines**, Boilers, Boats, Compasses, Cylinders, Fittings, Screws, Gauges, partly-finished Castings; uncommonly cheap.

**Batteries.**—Hundreds for all purposes. Most powerful constant. Convenient, durable. Connections, Carbons, Platinum, Jars, Cases, Chemicals.

**Medical Induction Apparatus**, Instruments of Research, Continuous Current Batteries (a pocket one 2s. 6d.), Baths, Books, &c.

**Electric Lighting.**—Dynamos, Batteries, Arc. Glow Lamps, Leads, Switches, Globes, Street Lamps, Lenses, Magnifiers. Hundred Accessories.—Caplatzi.

**Photography.**—Heap of Apparatus of all kinds. Good ½ Lens, 6s. ⅓, 12s. Excellent Stands, Baths.

**Catalogue, 2d. Caplatzi, Science Depot, Hire and Exchange, Chenies-street, Tottenham-court-road, near British Museum.**

**Models made for Inventors** accurate, neat, and economical.—Modelling Department, Co-Operative Patent Agency, Outer Temple, London.

**Drawings, Tracings**, &c., for Inventors, cheap and good.—Drawing Department, Co-Operative Patent Agency, Outer Temple, London.

Large quantity of **No. 20 Silk** at 3s. 6d., and 16 double cotton at 1s. 6d.

Unbreakable **Carbon Plates**. Reduced prices, 2½d. each. 7s. per quarter gross.

**To Bell Fitters and Others.**—Write for reduced List of Bells, Leclanche Batteries, and Materials for same.

**Bell Fitters' Sundries** supplied. All Goods guaranteed.—John H. Hindle, Irwell Vale, Helmshore, near Manchester.

Wanted, Inventions for Sale, or requiring Capital to develop.—Sale Department, Co-Operative Patent Agency, Outer Temple.

## Wanted.

Old Microscopes, by Adams, Amici, Baker, Dollond, B. Martin, Pritchard (Goring's "Engiscope"), Varley, and other old makers.—J. Mayall, Junior, 224, Regent-street, London, W.

Wanted, piece of well-seasoned Straight-grained Greenheart, 7ft. long by 3in. by 1⅞in.—Price to J. S., Holly Bank, Budleigh Salterton.

Deer Horns Wanted.—M. DAY, Hook and Handle Manufacturer, 57, Driffield-road, Old Ford, London.

Agents Wanted.—Morgan's celebrated Improved Scale Preventing Compound. Nothing better or cheaper.—W. H. Morgan, Engineer, Gloucester.

Wanted for cash, a good self-acting and screw-cutting Lathe, to take in between centres not less than six feet, price to include carriage either to one of the London Docks for conveyance here by own barge, or to Sittingbourne Station by L. C. and D. Railway.—State full particulars and price to J. Collins, Engineer, Elmsley Cement Factory, Nr. Sittingbourne, Kent.

Mediterranean.—Wanted to join some companionable person for few weeks on equal terms.—Address, B. B., Stainby's Library, 179, Sloane-street.

Wanted, Stained Glass Imitation; also letters to put on glass.—L. Harris, 21, Crossburn-street, Glasgow.

Wanted, "Otto" Silent Gas Engine, from two to four h.-p., in good working order.—R. Ruffett, 86, Richmond Villas, Huntingdon road, Cambridge.

Wanted, second-hand two man-power Gas Engine.—G. Absolon, 143, Packington-street, N.

Steam Boat (screw), about 7½in. wide, with or without engines.—To G., 234, Devonshire-street, E.

Wanted, small Model Tricycle Wheels, two 10in. dia., 3-16 rims, 30 steel spokes, 24 b.w.g., hubs 1¼in. long; one 4½in. dia., 15 spokes. All rubber tyres.—Lowest price to W., 5, Mitre-road, Ridley-road, Rochester, Kent.

Agents Wanted throughout this country and abroad by a firm of Electrical Engineers and Contractors manufacturing specialities, which meet with a large and ready sale.—X. Z., 211, Camden-road.

## Addresses.

To F. H. Wenham.—Traversing Mandrel Lathes.—Please send maker's name and particulars to Box 28, Southport.

Dr. EDMUNDS, 8, Grafton-street, Piccadilly, would be glad to communicate with "S. E. S.," so as to see the diamond tools to which he refers.

Address Wanted where to Purchase Mineral Oxides, Ochres, &c., in small quantities.—J. Tingle, Rothwell, Northamptonshire.

Address Wanted of Patent Agent having had experience in patents for textile fabrics or power-loom gearing.—G., care of Duncan and Co., 29, Mincing-lane, E.C.

## Situations.

Good Mechanic requires Situation as Foreman Toolmaker or repairs; 4½ years with Messrs. Rucker and Co., Cycle Manufacturers.—G. Farrell, 19, Robinson-road, Victoria Park, E., London.

---

ESTABLISHED 1851

**BIRKBECK BANK.—**

Southampton-buildings, Chancery-lane.

Current Accounts opened according to the usual practice of other Bankers, and Interest allowed on the minimum monthly balances, when not drawn below £50. No commission charged for keeping Accounts.

The Bank also receives money on Deposit at Three per cent. Interest, repayable on demand.

The Bank undertakes for its Customers, free of charge, the custody of Deeds, Writings, and other Securities and Valuables, the collection of Bills of Exchange, Dividends, and Coupons; and the purchase and Sale of Stocks and Shares.

Letters of Credit and Circular Notes issued.

A pamphlet, with full particulars, on application.

FRANCIS RAVENSCROFT, Manager.

31st March, 1880.

**The Birkbeck Building Society's Annual Receipts exceed Four Millions.**

**HOW TO PURCHASE A HOUSE** FOR TWO GUINEAS PER MONTH, with immediate Possession, and no Rent to pay. Apply at the Office of the BIRKBECK BUILDING SOCIETY.

**HOW TO PURCHASE A PLOT OF** LAND FOR FIVE SHILLINGS PER MONTH, with immediate possession, either for Building or Gardening purposes. Apply at the Office of the BIRKBECK FREEHOLD LAND SOCIETY.

*A Pamphlet with full particulars on application.*

FRANCIS RAVENSCROFT, Manager.

Southampton-buildings, Chancery-lane.

---

**ENGLISH MECHANICS** supplied with every requisite for ORGAN BUILDING and HARMONIUM MAKING at THOS. R. WILLIS'S, 29, Minories, London. Established 1827. Lists for stamp. All kinds of MUSICAL INSTRUMENTS, STRINGS, and FITTINGS. Some SOUNDBOARDS, KEYS, &c., for SALE. BARGAINS.

---

NOW READY,

HANDSOMELY BOUND IN CLOTH,

VOL XLVII.

OF THE

**BUILDING NEWS,**

PRICE TWELVE SHILLINGS.

Order at once of any bookseller, as only a limited number are bound up.

The English Mechanic
AND WORLD OF SCIENCE AND ART.
*FRIDAY, MARCH* 27, 1885.

## BOILER EXPLOSIONS IN 1884 AND THE BECKENHAM DISASTER.

IT is satisfactory to find that the records of boiler explosions during the past year compare favourably with those of any previous twelvemonth; for although the number of explosions is not quite so small as in 1879, it is less than in 1883, though the mortality is slightly greater. How much of the improvement is due to the Boiler Insurance and Inspection Companies, how much to the action of the Board of Trade, and how much to the exercise of greater care by steam-users, it is impossible to say; but it cannot be doubted that the system of inspection by disinterested experts has done a great deal in reducing the frequency of disasters of the kind, while the very existence of such associations has compelled, as it were, steam-users to be more careful. The number of explosions in 1884 was 32, causing the death of 22 persons, and injuring 48 others—figures which compare very favourably with those for 1874, when there were 76 explosions, killing 77 persons and injuring 198. The numbers fluctuate from year to year to a small extent; but since 1878 we may say that they are only half what they were in such years as 1874; and looking over the details of the explosions of 1884, there seems no reason why boiler explosions should not become sensations by their rarity. We will not go so far as to say that none of the 32 explosions of 1884 could be fairly set down as accidents, but it is incontestable that the great majority of them would have been prevented by timely inspection and adequate repairs or alterations. As usual in the list of purposes for which the boilers were used ironworks figure highly, about one-third of the total number being credited to them, while wood-working shops and farms are each responsible for four. It is easy to understand that boilers used for agricultural purposes do not receive so much skilled attention as those employed in factories; but where there is one boiler used on a farm there are hundreds used on railways, and yet only two of the explosions of 1884 occurred in connection with locomotives, because as a rule they are well looked after and frequently inspected. Of the 32 explosions in 1884, 18 were due to corrosion, 10 to faults which ought to have been detected by the attendants, such as shortness of water and over-pressure, and four to defects of construction or materials. Corrosion is, as usual, the principal cause, simply from the fact that it is most difficult to detect it unless the boiler is submitted to expert inspection at intervals, for although external corrosion offers sufficient signs to lead any careful person to suspect the real extent of the damage, it is only those familiar with the "diseases" of steam-boilers who know where to look for internal corrosion, the most insidious and dangerous of all boiler defects. The internal corrosion which produces "furrows" in the line of strain is the cause of many explosions which appear to the owners and tenders mysterious until the wasted metal is shown to them, and it is the cause which should bring home to the mind of all steam-users the absolute necessity of having a thorough inspection at least once a year. To take some of the instances of 1884, a vertical boiler with plates three-eighths of an inch thick, and not more than seven years old, ruptured at the flanged base of the uptake, where internal corrosion had reduced the metal to the thickness of a well-worn shilling. The "furrow" was produced by the expansion and contraction of the parts, and corrosion once started in such a place proceeds rapidly until the boiler gives way even at a moderate pressure, as in this case at 40lb. In another case a locomotive boiler used at an ironworks had $\frac{3}{8}$in. plates, was 12 years old, and was worked with 120lb. pressure. That gave way at a groove produced by internal corrosion through the continued bending of a plate backwards and forwards as the boiler was alternately heated and cooled down. In another locomotive boiler, this time in use on a railway, a longitudinal seam at the top of the barrel gave way behind the dome, the groove being so deep that only a skin was left. This is one of the few cases which might be fairly termed an accident, for the defect was in such a position that it could not be seen even by expert inspection, though its existence would have been detected if the hydraulic test had been applied. External corrosion is, of course, most dangerous when it occurs in parts hidden by brickwork, or other setting, though even in that case the existence of any serious wasting would scarcely escape the expert, and might be suspected by anyone blessed with a little common sense. Yet we find that a portable multitubular used at a farm was so corroded from the leaking of a feed pump, that at the point of rupture the original $\frac{1}{4}$in. plate had been reduced to about the thickness of tin plate. Here there was external corrosion without brickwork to hide it; but we must assume that no one detected what would have been at once apparent to an expert. A Cornish boiler used at a brickworks, and said to be ten years old, was so much corroded where it rested on brickwork, that it gave way along nearly the whole length of the shell while working at 45lb., although the plates were originally $\frac{3}{8}$in. thick. Such corrosion ought not to have escaped the attention of any boiler attendant when clearing the flues, but that such cases occur shows the necessity for skilled inspection. What, however, shall we say of another case, where a vertical, twelve years old, exploded because the plates round the bottom were corroded externally to such an extent that they were reduced to the thickness of a piece of stout paper! In the solitary instance of a printing-office boiler which exploded during 1884, the firebox was so reduced by external corrosion, that it was unable to bear the pressure. This case will be remembered from the extraordinary evidence of the manager of the works, who gave personal testimony of the incompetence of those under whose charge boilers are too often placed. One of the explosions last year occurred with a semi-waggon shaped boiler used to supply a chaff-cutting engine, and tended by a coachman, who was killed. The pressure might have been anything up to 100lb., as the spring balance was screwed down and could even be made fast. In another case, a "contractor's" boiler, which had no safety-valve, killed one person and injured three, because the pressure was allowed to accumulate until the firebox was forced inwards. We have said enough, however, to show that nearly every explosion could have been prevented or foreseen by inspection—foreseen, because even after inspection some owners will not do what is recommended, and will pooh-pooh warnings. The annual reports issued by the Steam-Users' Association and Boiler Insurance Companies demonstrate the fact that boiler explosions might be still further reduced in number, and those who are unacquainted with the subject may be referred to the illustrated reports which Mr. E. B. Martin, the chief engineer of the Midland Steam Boiler Inspection and Assurance Company, has issued for several years past. The explosion which occurred last month at Beckenham is another instance of the necessity for periodical inspection. The boiler in this case was of the Cornish type; but it had two furnaces, which led into one flue tube, the connecting piece being made up of no fewer than fourteen plates. The shell was over 15ft. long, with an internal diameter of 5ft. 7in. As to the pressure, it was stated at the inquest that it was usually 45lb. to 55lb.; but at least one witness said that he had seen the gauge standing at 63lb., while another stated that he had seen the safety-valves blowing off at 60lb. It seems probable, however, that the boiler had often been worked at higher pressures, for calculations show that the valves could be weighted to 76lb. and 84lb. respectively. These details have, however, only a subsidiary interest; the main fact is that the boiler exploded in consequence of the weakening caused by external corrosion from damp in the setting, and to the question of the coroner, "Was the dangerous state of the boiler known to those responsible for its being in proper condition?"—the jury returned an answer in the negative. To a further question whether the boiler was adequately examined for defects likely to arise in the course of time, the jury answered "No"; and to another question, whether there was any wilful, criminal, or gross culpable negligence shown by any person responsible for the working of the boiler, the jury again answered "No"; and when the further question was put, "Were the latent defects undetected through ignorance, or through an error of judgment?" the jury replied, "Through an error of judgment. It is not easy always to draw the line between simple negligence, and that gross, culpable negligence which comes within the grasp of the criminal law; but here we have a boiler which exploded because it was in a perfectly unfit state to be trusted at all—a fact which ought to have been at least suspected by everyone acquainted with it. Eleven years ago, it appears, the boiler was lying in the yard of a second-hand dealer, and was then tested by the hydraulic method up to 110lb. The company to whom it was sold never used it more than two or three times, and in the end of 1877 it was put into position at the brickworks, was examined by a firm of boiler makers, and tested with the water-pump to 110lb. So far there seems no reason to suppose that the boiler was not capable of doing its work; but where it was erected at the brickworks it appears that water in a pond at the back of the boiler was at a higher level than the stokehole, and water came through the ground to such an extent that the first man who had charge put in a drain to lead it off. Other witnesses gave evidence which proved conclusively that the dampness of the seating of the boiler was well known, and an examination of the plates proved that the cause of the rupture was the severe external corrosion, which in parts had reduced the plates to a thickness of less than the sixteenth of an inch, and at some points probably the metal was corroded quite through. It is incontestable that this corrosion would have been detected by expert inspection, and it is impossible to believe that any boiler attendant possessed of a little common sense would have failed to discover the serious weakening of the plates if he had ever used his hammer when making a perfunctory examination. The engine driver who had charge of the boiler up to the spring of 1883 thought it all right when he left it, and would have trusted it another seven years with 70lb. of steam; but it is almost certain that if the boiler had been examined by one of the inspecting companies at the time it was first put into the brickworks, the limit of pressure would have been fixed at 45lb. or less, while the dangerous character of the seating would have been pointed out.

In the reports which have been issued annually for many years, clear and unmistakable warnings have been given over and over again of the risk run through external corrosion from damp seatings; but the jury in the Beckenham case acquit those responsible for the careful working of the boiler, declare that there was no culpable negligence, and that the defects were undetected "through an error of judgment." Compulsory legislation in matters of this kind is very naturally disliked by everyone; but if there are many more boiler explosions like that at Beckenham, it will be absolutely necessary to insist upon periodical inspections and all sorts of repairs and alterations. It will be better for boiler owners to take warning in time, and render legislation unnecessary by doing all they can to prevent explosions.

## NOTES ON CASSEGRAINS.—II.

By Dr. Royston-Pigott, F.R.S.

### Construction.

ANYONE attempting to design a Cassegrain must first of all dismiss the ridiculous notion that the instrument, when in working order, must be so arranged that the focus of the small convex (always behind it) must coincide with the focus of the large parabolic. If we call the point F the sidereal focus of the big mirror, and *f* the point where the focus of the convex oscillates, there is a space F*f*—

A B F

and (*f*) lies beyond F by a space F*f*. And the magnifying power of the whole system for the same eyepiece varies inversely as the distance between these foci, and, as it is a variable, it will be well represented by the quantity $x$. It is next to impossible, when the foci are even perfectly known, to decide upon the position of the small convex (*f*) unless its distance ($x$) from F be calculated beforehand, and for this purpose I know no better formula than the following approximation, carefully determined, on the supposition that convex focus is one-fifth of the concave focus.

$$x_5 = 0{\cdot}038\ \mathrm{F} \text{ or } = \frac{38}{1000} \text{ of F.}$$

If the convex has a focus only ¼ of F,

$$x_4 = 0{\cdot}059\ \mathrm{F} \text{ or } = \frac{59}{1000} \text{ of F.}$$

This algebraic formula is approximately true—

$$\mathrm{F}x + x^2 = f^2$$

$$\text{Whence} \quad x = \sqrt{\frac{\mathrm{F}^2}{4} + f^2} - \frac{\mathrm{F}}{2}$$

And if F = 5*f*, taking positive sign—

$$x = \sqrt{\frac{\mathrm{F}^2}{4} + \frac{\mathrm{F}^2}{25}} - \frac{\mathrm{F}}{2} = \sqrt{\frac{29\,\mathrm{F}^2}{100}} - \frac{\mathrm{F}}{2} = 0{\cdot}038\mathrm{F}$$

### Magnifying Powers.

The moment we can get the value of $x$—i.e., the distance of the convex focus from the great focus—viz., F*f*, the magnifying power (M) for a given eyepiece with focus E is known—

$$\mathrm{M} = \frac{\mathrm{F}}{\mathrm{E}} \times \frac{f}{x}$$

Example. In my Cassegrain the lowest power with 4¼in. eyepiece and 28½in. convex, and great focus 129in.

$$\mathrm{M} = \frac{129}{4\frac{1}{4}} \times \frac{28\frac{1}{2}}{4{\cdot}9}{}^{*}$$

$$= 30{\cdot}3 \times 5{\cdot}82 = 175 \text{ nearly.}$$

It will be observed the magnifying power changes not in proportion to the focus of the convex, but as the ratio of this to its distance from the great focus.

It is important for anyone about to construct a Cassegrain to know how to place a given convex in position at once by actual measurement. Of course, if a vertical rod be suspended above, the length from the hinge or ball and socket measured to the surface should be exactly half of the proposed focal length (*f*).

Take the Melbourne Cassegrain focus F = 30½ft. = 366in.; focus of convex = 74·71in. Find the position for the convex surface. The dist. of it from the great focus is $x$ in the equation (approximately).

$$\mathrm{F}x + x^2 = f^2$$

Solving the equation, by adding to complete the square—

$$x^2 + \mathrm{F}x = f^2$$

$$\frac{\mathrm{F}^2}{4} = \frac{\mathrm{F}^2}{4}$$

$$x^2 + \mathrm{F}x + \frac{\mathrm{F}^2}{4} = f^2 + \frac{\mathrm{F}^2}{4}$$

Square rooting—

$$x + \frac{\mathrm{F}}{2} = \pm\sqrt{f^2 + \frac{\mathrm{F}^2}{4}}$$

(The *plus* sign only is required), so transposing—

$$x = \sqrt{f^2 + \frac{\mathrm{F}^2}{4}} - \frac{\mathrm{F}}{2}$$

Now, in the monster Melbourne Cassegrain—

$$f = 74{\cdot}71\text{in.}, \ \mathrm{F} = 366\text{in.}$$

Then—

$$x = \sqrt{(74{\cdot}71)^2 + \frac{(366)^2}{4}} - \frac{366}{2}$$

$$= \sqrt{5582 + 33489} - 183$$

$$= \sqrt{39071} - 183 = 197{\cdot}5 - 183$$

$$= 14{\cdot}5, \text{ the approximate position.}$$

This is correct for the monster telescope at Melbourne within about ¾in.

The Melbourne telescope's concave mirror A is 366in., and small convex 71·74in. focus; while dist. of its surface from great focus is 61in., and from its own focus 71·74, leaving the difference $x$ = 13·71, and focus of eyepiece E = 8·05 (I believe it is really 8in.).

*f* F 61 B A.

Then, the magnifying power as before—

$$\frac{\mathrm{F}}{\mathrm{E}} \cdot \frac{f}{x}$$

$$\mathrm{M} = \frac{366 \times 71{\cdot}74}{8{\cdot}05 \times 13{\cdot}71}$$

Taking the logarithms—

$$\log. \mathrm{M} = \log. 366 + \log. 71{\cdot}74 - \log. 8{\cdot}05 - \log. 13{\cdot}71$$

$$\begin{array}{rr} = 2{\cdot}5634811 & -\,0{\cdot}9057959 \\ 1{\cdot}8557614 & -\,0{\cdot}1370375 \\ \hline 4{\cdot}4192425 & -\,1{\cdot}0428334 \\ -\,1{\cdot}0428334 & \\ \hline 3{\cdot}3764091 & \end{array}$$

And, therefore, M = 237·9, which is 1 per cent. less than the value assigned at Melbourne 240. That the formula—

$$\mathrm{M} = \frac{\mathrm{F} \times f}{\mathrm{E} \times x}$$

is sufficiently near is quite evident.

For my Cassegrain, A being centre of concave and B of (*f*), in this diagram, A F = 129in., B*f* = ⅕ 129 = 25·8in. F*f* = $x$ = 4·96; and B F (as F is a fixed point) = B*f* − F*f* = 25·8 − 4·9 = 20·9, so that the surface of the convex must be placed at B where B F = 20·9in.

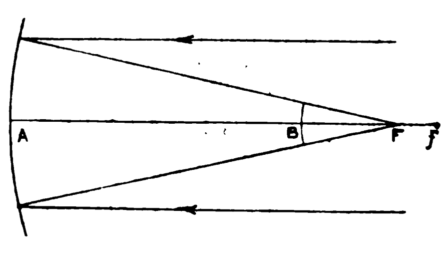
$$\text{The magnifying power} = \frac{\mathrm{F}}{\mathrm{E}} \cdot \frac{f}{x}$$

$$(\text{If } 3\tfrac{1}{2} = \mathrm{E}) \qquad = \frac{129}{3\frac{1}{2}} \times \frac{25{\cdot}8}{4{\cdot}96}$$

$$= 191{\cdot}5 \text{ nearly.}$$

The proportion of foci—the large concave to have five times the focal length of the small convex, is as good as possible.

In viewing the convex in position through the aperture in concave, the reflected image should just embrace the whole of the convex. If the convex be too large, a black margin will be seen all round the convex, which causes a larger black spot in the eyepiece than necessary; besides obstructing light and darkening the field of view.



The small convex being 20·9in. outside or beyond the convex, a cone of light converging thither will almost exactly fill the convex with light coming from an 18in. mirror; with the condition that the convex is 3 1-16in. in diameter. A very important point is to keep down the size of the black spot on the eyepiece. In the case just given the diameter of this

$$\delta = \frac{3}{190} \text{ nearly} = \frac{1}{63}\text{rd of an inch.}$$

Whilst the final pencil has a diameter of $\frac{18}{190}$ $= \frac{1}{10{\cdot}5}$ nearly, which darkens about $\frac{1}{27}$th of the whole pencil.

It may be remarked here that an eyepiece of 7in. focus would give a power of 95 with great brilliancy, with the convex of 28½in.

The field of view for power 190 would be—

$$\theta = \frac{\text{co-tangent 1 minute}}{\text{magnifying power}}$$

$$= \frac{3438}{190} = 18 \text{ minutes.}$$

This would embrace rather more than half the moon's disc. The great difficulty in this form of telescope is to keep down the final diameter of the moon's image. It is only by lengthening the focus *f*, or shortening F, this can be done. At the same time it should be stated that no other form of telescope can display so large a lunar image. In the case now discussed, the size of the image presented at the aperture of the concave mirror is just about 5¼ larger than would be produced by a Newtonian of the same parabolic focus F, equivalent, indeed, to that produced by an achromatic or Newtonian of 56ft.

There are some special advantages belonging to this virtual focus. The moon is so enormously magnified at first hand that a very low eye-lens—especially short-focus photo-lenses—can be employed, producing remarkable precision of definition, whilst the light being spread over so large a surface, is pleasantly subdued to a pearly brilliance.

(*To be continued.*)

---

* ($x$ = 0·038 F = 0·038 × 129 = 4·902in.; say 4·9.)

Then for a convex of one-fourth the focus of F = ¼ 129 = 32¼ $x$ = ·059 F = 7·63.

$$\mathrm{M} = \frac{\mathrm{F}}{4\frac{1}{4}} \cdot \frac{f}{x} = \frac{129}{4\frac{1}{4}} \times \frac{32\frac{1}{4}}{7{\cdot}63} = 30{\cdot}3 \times 4{\cdot}22 = 128$$

## SOLID v. LAMINATED ARMATURES.

By Selimo R. Bottone.

CONTRADICTORY statements have appeared in several publications devoted to electrical matters as to the relative efficiency of solid and laminated armatures. In manufacture, a laminated armature is certainly more expensive: hence it must present some decided advantage over the solid form to insure its adoption.

In order to decide the point by actual experiment, the writer fitted up a small dynamo (one of those described in his book) with 7lb. of No. 16 c.c. copper wire on the fields. Two armatures, each 1½in. in diameter, 3¾in. in length, with a channel ⅞in. wide, and a web ¼in. in thickness—one (*a*) solid, weighing 13oz., the other (*b*) laminated, weighing 11oz.—were each wound with 6oz. of No. 20 silk-covered wire, and then soaked in melted paraffin to insure good insulation. These were both mounted on spindles of the same size, fitted with similar commutators, and, in point of fact, rendered as identical as it was possible for them to be except in the point of lamination.

When the solid armature (*a*) was fitted to the dynamo, worked as a series machine, it was possible, by driving at a speed of about 3,000 revolutions per minute, to light fairly well four five-candle Swan lamps, arranged in parallel arc, having each a resistance of 8 ohms. At this speed the electromotive force was about 10 volts at the terminals.

The laminated armature (*b*) was now substituted, and on trial it was found that the five-candle Swan lamps could be kept brilliantly lighted by a speed of 2,000 revolutions per minute. On adding lamps, and increasing the speed, it was found that six and even seven fives could be lighted up, and at 3,000 revs. the effect with six was as good as the solid armature gave with four. The electromotive force of this machine at this speed was found on careful measurement to be about 20 volts; and, in point of fact, it was possible to light well three ten-candle Swans in parallel arc each of 20 ohms resistance. With regard to heating, (*a*) rose from a temperature of

45° Fahr. to 120° after a twenty minutes run; (*b*) after running twenty minutes had only increased 5°.

In order to render the experiments more conclusive, two exactly similar motors were fitted up, alike at all points except in the armatures. The armatures (*a*) and (*b*) were fitted to these motors, but so as to be interchangeable at will. No material difference was, however, detected in the field-magnets. These two motors were connected up in series, but back to front, so as to get the driving-wheels to run in opposite directions. The two driving-wheels were then joined together by an endless band, and the motors joined to one and the same battery (so that the same current circulated round both at the same time).

The result was that the motor fitted with the laminated (*b*) armature began to revolve, dragging with it armature (*a*), which was thus obliged to rotate in a direction opposite to that in which it was impelled by its own field-magnets.

To what may this superiority be attributed? Probably three causes are at work simultaneously.

1. The sheet iron from which the laminated armature was made is softer, more free from carbon, and purer than it is possible for cast iron to be; hence more rapid and more perfect magnetisation and demagnetisation.

2. The lamination, and consequent separation of the portions of the armature, prevents the formation of the Foucault currents; therefore, the iron cone does not get heated.

3. The interstices between the laminations, by allowing the passage of air, help to keep the armature cool; and the coolness of the armature favours the conductivity of the wire, and consequently the efficiency of the machine.

## ASTRONOMICAL NOTES FOR APRIL, 1885.

### The Sun.

| Day of Month. | Souths. | At Greenwich Mean Noon. | | |
|---|---|---|---|---|
| | | Right Ascension. | Declination North. | Sidereal Time. |
| | h. m. s. p.m. | h. m. s. | ° ′ ″ | h. m. s. |

| 6 | 0 2 20·77 ,, | 1 2 6 | 6 37 23 | 0 59 44·96 |
| 11 | 0 0 57·46 ,, | 1 20 25 | 8 28 53 | 1 19 27·73 |
| 16 | 11 59 41·79 A.M. | 1 38 52 | 10 16 53 | 1 39 10·49 |
| 21 | 11 58 35·35 ,, | 1 57 29 | 12 0 39 | 1 58 53·25 |
| 26 | 11 57 39·44 ,, | 2 16 15 | 13 39 27 | 2 18 36·02 |

The method of finding the Local Sidereal Time at Mean Noon at any other Station will be found on p. 355 of Vol. XL.

Although the sunspot maximum has now passed, interesting groups of spots, faculæ, &c., continue to reward the assiduous observer.

The Zodiacal light may still be seen during the first part of the month.

### The Moon

Enters her Last Quarter at 2h. 42·6m. in the afternoon of the 7th, and is New at 5h. 51·4m. a.m. on the 15th. She will enter her First Quarter at 11h. 20·2m. at night on the 21st, and be Full at 6h. 14·3m. in the morning of the 29th.

| Day of Month. | Moon's Age at Noon. | Souths. |
|---|---|---|
| | Days. | h. m. |
| 1 | 15·8 | 1 8·1 a.m. |
| 6 | 20·8 | 5 6·8 ,, |
| 11 | 25·8 | 9 0·0 ,, |
| 16 | 1·3 | 1 10·5 p.m. |
| 21 | 6·3 | 6 0·0 ,, |
| 26 | 11·3 | 10 14·2 ,, |

The Moon will be in conjunction with Mars at 6 a.m. on the 14th; with Venus at 8 p.m. on the same day; with Mercury at 7 a.m. on the 16th; with Saturn at 1 a.m. on the 19th; and with Jupiter at 7 p.m. on the 23rd.

Ec Eclipse; Oc Occultation; Tr Transit of Satellite; Sh Transit of Shadow; D Disappearance; R Reappearance; I Ingress; E Egress. The printing of a phenomenon in *italics* indicates that its visibility is rendered doubtful, either by the brightness of the twilight or by Jupiter's proximity to the horizon.

### Mercury

Is an Evening Star up to the 27th. At 3 a.m. on the 28th he comes into inferior conjunction with the Sun, and, of course, afterwards travels to the West of him, and becomes a Morning Star. He attains his greatest elongation East (19° 15′) at 2 a.m. on the 8th, and is, during the first ten days of April, excellently situated for the observer, who, on clear evenings, may pick the planet up above the Western horison with the naked eye.

| Day of Month. | Right Ascension. | Declination North. | Souths. |
|---|---|---|---|
| | h. m. | ° ′ | h. m. |
| 1 | 1 46·2 | 12 47·9 | 1 6·0 p.m. |
| 6 | 2 11·4 | 15 54·1 | 1 11·4 ,, |
| 11 | 2 28·2 | 17 46·8 | 1 8·5 ,, |
| 16 | 2 35·4 | 18 20·3 | 0 56·1 ,, |
| 21 | 2 33·5 | 17 35·2 | 0 34·5 ,, |
| 26 | 2 24·9 | 15 45·9 | 0 6·2 ,, |

The path indicated by the above Ephemeris commences where Cetus, Pisces, and Aries are conterminous, and extends into the last-named constellation. On the same day that he comes into inferior conjunction with the Sun, he will, at 7 p.m., be in conjunction with Venus—it is needless to say invisibly.

### Venus

Is a Morning Star, and is at once an object devoid of all interest, and in a most indifferent position for the observer. She is immersed in the glare of sunlight, and the diameter of her practically circular disc dwindles from 9·8″ at the beginning of April to 9·6″ by the end of it.

### Venus.

| Day of Month. | Right Ascension. | Declination. | Souths. |
|---|---|---|---|
| | h. m. | ° ′ | h. m. |
| 1 | 0 14·3 | 0 1·4 S. | 11 34 3 a.m. |
| 6 | 0 37·0 | 2 27·9 N. | 11 37·3 ,, |
| 11 | 0 59·8 | 4 56·1 ,, | 11 40·4 ,, |
| 16 | 1 22·7 | 7 21·8 ,, | 11 43·5 ,, |
| 21 | 1 45·8 | 9 43·5 ,, | 11 46·9 ,, |
| 26 | 2 9·2 | 11 59·6 ,, | 11 50·6 ,, |

Hence, starting from Pisces, Venus travels across the North-West course of Cetus into Aries.

### Mars

Is invisible. To those who care to look at the Minor Planets,

### Ceres

Comes into Opposition to the Sun on April 2nd, and is hence well situated for observation. Our Ephemeris is, as usual in these cases, for ten-day intervals only. The planet shines as a 7th magnitude star.

| Day of Month. | Right Ascension. | Declination North. | Souths. |
|---|---|---|---|
| | h. m. | ° ′ | h. m. |
| 1 | 13 14·2 | 9 19·3 | 12 32·2 p.m. |
| 11 | 13 5·6 | 9 49·4 | 11 44·2 ,, |
| 21 | 12 57·4 | 10 0·0 | 10 56·7 ,, |

Ceres will thus retrograde through a short arc in a very barren part of Virgo. On the night of the 22nd she will be a very little more than 1½° South of ε in that constellation.

### Pallas

Was, as stated on p. 553 of our last volume, in opposition on March 17, so that she may still be well seen during the earlier part of the night. She presents the appearance of a bright 7th mag. star, of a yellowish tint.

| Day of Month. | Right Ascension. | Declination North. | Souths. |
|---|---|---|---|
| | h. m. | ° ′ | h. m. |
| 1 | 11 51·1 | 11 55·2 | 11 9·3 p.m. |
| 11 | 11 46·0 | 14 51·9 | 10 24·9 ,, |
| 21 | 11 43·2 | 17 5·3 | 9 42·7 ,, |

Starting from the confines of Virgo, Pallas will travel into Leo. She will be almost exactly 1½° North of β Leonis on the 18th.

### Juno

Will be in opposition to the Sun on April 15th. Her light is of an orange cast, and she looks like an eighth-magnitude star.

| Day of Month. | Right Ascension. | Declination. | Souths. |
|---|---|---|---|
| | h. m. | ° ″ | h. m. |
| 1 | 14 3·8 | 1 35·3 S. | 1 25·5 a.m. |
| 11 | 13 55·6 | 0 11·9 ,, | 12 34.1 p.m. |
| 21 | 13 47·7 | 0 57·4 N. | 11 46·9 ,, |

Juno is in Virgo, too, in a blank part of the sky. On the nights of the 10th and 11th she may be fished for a little more than 2° South of τ Virginis—a wide and unequal double Star.

### Jupiter

Is approaching the West, but is still king of the night sky. He should be observed as soon as it is dark enough, in order to be seen to the greatest advantage. His angular diameter slowly decreases from 39·6″ on April 1st to 36·5 on the last day of the month.

| Day of Month. | Right Ascension. | Declination North. | Souths. |
|---|---|---|---|
| | h. m. | ° ′ | h. m. |
| 1 | 9 56·5 | 13 52·4 | 9 15·0 p.m. |
| 6 | 9 55·4 | 13 57·3 | 8 54·2 ,, |
| 11 | 9 54·7 | 14 0·7 | 8 33·8 ,, |
| 16 | 9 54·2 | 14 2·4 | 8 13·7 ,, |
| 21 | 9 54·0 | 14 2·5 | 7 53·8 ,, |
| 26 | 9 54·2 | 14 1·1 | 7 34·3 ,, |

As shown by the above Ephemeris, Jupiter will, to the naked eye, remain sensibly stationary in Leo, a little to the West and North of Regulus.

### Saturn

Now souths in bright daylight, sets soon after midnight at the beginning of the month, and, of course, sooner and sooner every night. We last month intimated our intention (Vol. XL., p. 553) of discontinuing our Ephemeris of him; but as he may still be seen for a short time after dark in the West and West-North-West, we subjoin one for the first half of April.

| Day of Month. | Right Ascension. | Declination North. | Souths. |
|---|---|---|---|
| | h. m. | ° ′ | h. m. |
| 1 | 5 12·6 | 21 52·9 | 4 31·8 p.m. |
| 6 | 5 14·3 | 21 55·7 | 4 13·9 ,, |
| 11 | 5 16·1 | 21 58·6 | 3 56·0 ,, |

So that Saturn, during the short remaining time of his visibility, will continue at the right-hand extremity of the base of the rudely isosceles triangle which he forms with β and ζ Tauri.

### Uranus

Is still capitally placed for the observer, and is in his best position during the most convenient hours of the night. His angular diameter of 4″ remains unaltered.

| Day of Month. | Right Ascension. | Declination North. | Souths. |
|---|---|---|---|
| | h. m. | ° ′ | h. m. |
| 1 | 12 2·7 | 0 33·3 | 11 24·9 p.m. |
| 6 | 12 1·9 | 0 38·2 | 11 0·4 ,, |
| 11 | 12 1·2 | 0 42·8 | 10 40·0 ,, |
| 16 | 12 0 5 | 0 47·3 | 10 19·7 ,, |
| 21 | 11 59·9 | 0 51·4 | 9 59·3 ,, |
| 26 | 11 59·2 | 0 55·2 | 9 39·0 ,, |

Hence it will be seen that Uranus is travelling through a short retrograde arc away from η Virginis, and in the direction of β in that constellation.

### Neptune

Is invisible.

### Shooting Stars

Should be watched for from the 19th to the 21st, and notably on the 20th. A look-out should also be kept from the 26th to the 30th.

### Greenwich Mean Time of Southing of Nine of the Principal Fixed Stars on the Night of April 1st, 1885.

| Star. | Souths. h. | m. | s. | |
|---|---|---|---|---|
| β Cancri .. .. .. | 7 | 29 | 1·96 | p.m. |
| ι Ursæ Majoris .. .. | 8 | 9 | 58·62 | ,, |
| α Hydræ .. .. .. | 8 | 40 | 30·03 | ,, |
| Regulus .. .. .. | 9 | 20 | 42·15 | ,, |
| α Ursæ Majoris .. .. | 10 | 14 | 56·40 | ,, |
| δ Crateris .. .. .. | 10 | 31 | 51·61 | ,, |
| ε Corvi .. .. .. .. | 11 | 22 | 20·74 | ,, |
| α Canum Venaticorum .. | 12 | 8 | 38·85 | ,, |
| Spica Virginis .. .. .. | 12 | 37 | 1·70 | ,, |

The method of finding the Greenwich Mean Time of Southing of either of the Stars in the above list for any other night in April, as also that of determining the local instant of its Transit at any other Station, will be found on p. 356 of Vol. XL.

## COMPOUND EYES AND MULTIPLE IMAGES.[*]

MY microscopical recreations the past summer were directed mainly upon the structure of the compound eyes of insects, not so much for a definite scientific purpose, as with the practical object of discovering what insects have eyes that are the most serviceable for showing multiple images under the microscope. The results thus far obtained are far from exhaustive; yet I have fallen upon some curious features in the structure of these organs, which may possess the interest of novelty to an audience not composed exclusively of entomologists.

These compound eyes, consisting externally of a great number of lenses, sometimes exceeding twenty thousand, set in a framework of convex or, often, hemispherical form, have a range of vision, or "angular aperture," very much larger than could be commanded by a simple eye of the same convexity. For, while the simple eye could form correct images of those objects only which are situated within the range of rays passing through its optical axis, the minute lenses composing the compound eye may, many of them, receive light from a horizon as low down as the base of the entire set, if not lower.

In some species of Neuroptera the head is nearly cylindrical, and is placed with its axis transverse to the axis of the insect's body. As the eyes constituting, of course, the extremities of the cylinder, have a diameter exceeding that of their support, and are, besides, hyperhemispherical, they give to the head the appearance of a dumbbell. Were one of these insects placed at the centre of a hollow sphere, it could, undoubtedly, see at the same moment every point of the sphere's interior surface.

The *Gyrinus*, or water-beetle, which may be seen sporting on the surface of still water in summer, has the unusual number of four compound eyes. Besides the usual pair on the upper and frontal part of the head, set in the under side of head is another pair, looking directly downward and completely submerged — "water-immersion" eyes. The utility of this arrangement is readily seen. Its anatomy I have not myself examined; but I have somewhere heard or read that the two eyes on each side, though separated externally, are, in a measure, connected internally. The *Gyrinus* is the only example of this peculiar structure that has come under my observation.

To those who admire colour, a microscopical observation of the eyes of living insects, especially those of the order Diptera, and of the night-flying Lepidoptera, will be fruitful of delight. For the eyes of these insects display an endless variety of colours which vie in brilliancy with the most lustrous of the "bright jewels of the mine." After the death of the insect, however, the colour soon disappears.

In mounting compound eyes for the purpose of showing multiple images, the first step, after carefully washing the interior of the cornea, is to press the cornea flat, so that all the lenses may lie as nearly as possible in the same plane. But as this operation necessarily occasions either a breaking or folding of the cornea, I cut out, with a small punch made for the purpose, a circular disc not larger than can be pressed flat without disturbing the facets. In punching out these discs, a single cutting gives two circular pieces, showing that the cornea is double; and in the eyes of *Cicada*, a single cutting gives three separate discs showing a triple set of lenses in the cornea. Each set constitutes, without doubt, an achromatic combination.

In some of the Diptera, particularly of the genus *Tabanus*, or horse-fly, the lenses of the upper and anterior part of the eye are much larger than those situated below a median line. A disc cut from one of these eyes in such a way as to include a number of the upper or larger facets, and also some of the lower, shows that the larger facets have at least twice the diameter of the smaller, or four times their superficial area. A still more remarkable feature, however, is the difference in focus between the larger lenses and the smaller. For upon placing this part of the eye upon the stages of the microscope, and adjusting the focus for multiple images, I found that the larger lenses form pictures at a plane considerably above the focal plane of the smaller ones. From this fact it would appear that these insects are furnished with eyes of two varieties, corresponding to our long-sight and short-sight spectacles; in other words, telescopic and microscopical eyes, the telescopic looking upward and forward, and the microscopical downward. The economy of such an optical structure in a parasitic insect which seeks its prey at a distance is so obvious that I need not stop to explain it.

For showing multiple images, the most perfect eyes that I have yet found are those of *Blattia orientalis*, or the cockroach. As the eyes of the insect are quite brittle, only a small part of the cornea can be pressed flat in one piece. Yet a piece large enough to fill the field commanded by a ¼in. objective and a B ocular can be cut out with the punch. The many advantages which it possesses more than counterbalance its lack of superficial extent. For the lenses are very transparent, and comparatively large, and, being set in a moderately-hard framework, do not separate so as to destroy the achromatic combination. Nor do the lenses which make up each combination slip upon one another when subjected to slight pressure, as do the lenses in the eyes of most other insects except the coleoptera. When the lenses do thus slip upon one another, each separate eye shows two or three imperfect images instead of a single good one. The chief advantage, however, which the eyes of the cockroach possess over all others is that they may be mounted in glycerine and thus kept perfectly transparent without losing their properties as lenses.

The usual method of exhibiting the multiple images is to place the mounted cornea of the compound eye upon the stage, and focus the microscope so much above it as to show a clear circle of light in each facet. Then, if any small object be placed between the stage and the mirror, its image will be exhibited by every lens. Also if a small letter, figure, or picture, in black, with a clear, white background, be placed 1in. or 2in. below the stage, and a strong light be condensed upon it, it will be seen with tolerable distinctness. Such objects are, however, much more sharply defined if first cut out, and then pasted upon a thin cover-glass, which may be mounted on the substage. In this situation the object is illumined by light reflected from the mirror. The effect will be still better if a slip of ground glass be interposed between the object and the mirror, so as to shut off the image of the lamp if lamplight be employed, or of distant objects, if daylight be used. The eye of a mosquito will show two or three hundred pictures of a person, in silhouette, with great distinctness, provided you have a window so situated as to allow light from the sky or from a white cloud to pass unobstructed to the mirror. The person must stand at a distance of 5ft. or 6ft. from the microscope, and with the profile of his face in clear relief against the sky. The plane mirror must, of course, be used.

I have recently been much interested in examining the structure of the eye of *Limulus*, or the horse-shoe crab, which, though compound, is quite different, in some particulars, from that of insects.

---

[*] By J. D. Hyatt, from the *Journal* of the New York Microscopical Society.

The exterior of this eye is perfectly smooth, and consists of a transparent horny coat of considerable thickness. The concave interior surface is studed with lenses varying in form from plano-convex, near the centre, to conical and paraboloid, toward and at the periphery. These lenses are so placed that their optical axes converge to a common point situated in a plane a little below the base of the whole eye. This point, without doubt, is occupied by the retina, or the extremity of the optic nerve. Good multiple images will be made by this eye if a small disc cut from the central part be used, the eye being flattest at that point and the lenses least conical. From any other part of the eye it would be extremely difficult to cut a disc that would not, in consequence of the oblique position of the lenses, greatly distort the images.

Multiple images may be formed under the microscope in many other ways than by the use of compound eyes. The minute plano-convex bodies of water produced by breathing on a slide, will display good images of any small object supported above the mirror. In like manner, images will be made by other transparent bodies, or by the transparent parts of any structure, which are of lenticular or globular form. Concave lenses, as well as convex, will give images, but with this difference —the images will be found below the plane of the foci of the lenses, and will be inverted; whereas, images produced by convex lenses are formed erect and, as before stated, at a plane above such focus. It follows that air-bubbles in water will yield inverted images, the water immediately surrounding them acting as a biconcave lens. These facts may possibly be of some service in determining the character of minute bodies or structures, such, for example, as human blood corpuscles, all of which show erect images—a proof that they are nucleated or, at least, lenticular at the centre. The head of the pin-shaped sponge-spicule, and the nuclei in certain diatoms, produce inverted images.

## THE DANGERS OF MECHANICAL GENERATORS OF ELECTRICITY.*

THE more and more general use of powerful electro-magnetic generators has caused several accidents, some of them involving the loss of human life. It is, therefore, desired at present to regulate the employment of electricity, and to determine experimentally the tension and the current which are dangerous in practice. The problem thus set forth is not well put, and is not susceptible of any solution, as the object of the present communication is to show. In the first place, it is not, generally, when the electric current is permanently established that accidents take place, but at the moment of the establishment or of the rupture of the electric circuit. Under these circumstances, the body of the experimentalist re-establishes for a longer or shorter time the continuity of the broken circuit. It is easy to show that, at this moment, the danger incurred depends by no means on the tension and the intensity of the primitive current, as is generally believed, but depends on quite a different factor, which cannot be calculated from a mere knowledge of the tension and the intensity of this primitive current. All physiologists know that the energy of an electric excitement depends much less on the intensity of the current than on the rapidity of the fall of the potential and on the frequency of the shocks. This being established, the following propositions become, so to speak, self-evident:—Proposition I.—A battery and a machine producing in a rectilineal circuit two currents having the same current and the same tension do not present the same dangers. In fact, if we break the circuit in any point whatever, holding in each hand an end of the uninsulated wire, we find that the battery gives scarcely a shock, whilst the machine produces a much more considerable excitement of the nervous and muscular systems—an excitement which, in certain cases, may become instantaneously fatal. The reason of this difference is that the battery in a rectilineal circuit does not give an extra current, whilst the machine, by the mere fact of its construction, gives one, the power of which varies with the length and the manner of coiling of its circuit, as well as with the quantity of iron which forms its framework. The danger, therefore, resides simply in the power of the extra current resulting from the self-induction of the generator. From these very simple considerations, the results of experience, we deduce the following propositions:—Proposition II.—Two machines yielding currents of the same intensity and the same tension in a similar circuit may be unequally dangerous, since their coefficients of self-induction, and consequently their extra currents, may be very different. Proposition III.—A current not dangerous in one circuit may be dangerous in another. It is merely necessary to give the circuit a self-induction by any means whatever—*e.g.*, by the interposition of an electro-magnet. I have verified experimentally these theoretical deductions by operating upon Guinea pigs with a Gramme machine (laboratory model) and with accumulators. The tension of the currents employed varied only from 2 to 20 volts, and the current from 1 to 30 ampères. Notwithstanding the feebleness of the currents employed, the Guinea pigs were nevertheless killed. We see, therefore, that, if we wish to suppress all danger in the use of electricity, we arrive at the absurd conclusion that electricity itself must be suppressed. I have sought for a remedy for this state of things. This is the method which has proved efficacious in all cases, and which constitutes a general procedure for the suppression of extra currents. To avoid all danger, what, in short, must be done? Simply prevent the extra current from traversing the body of the experimentalist. We know that the tension of the extra current is infinitely greater than that of the primitive current from which it takes its rise. This being admitted, I place in derivation at the extremities of the electric generator a series of voltameters, with lead plates and acidulated water, in such a number that their electromotive force of polarization may be superior to the maximum electromotive force of the machine. This derivation is absolutely impassable by the direct current, while the extra current traverses it readily. At the moment when the circuit is broken the extra current passes through the voltameters, and the human body is absolutely secure. This is a general and very simple method for the suppression of extra currents. It admits of numerous applications, some of which I have already carried out, but their explanation cannot be given in this brief notice. I take voltameters with leaden plates because they develop practically the greatest electromotive force, and I vary the arrangement according to circumstances. We see that the process which I propose consists in the establishment of a derivation, insurmountable for a direct current, and consequently occasioning no waste of current. This derivation exists only for the extra current. It is analogous to a safety valve, which opens automatically at a given pressure.

## HOME-MADE EMERY WHEELS.

THE solid emery wheels have made possible a wonderful advance in the surfacing and poling of metals in the shop, in truing centres, sharpening tools, and in other processes. Yet in some cases they are not equal to the home-made wheel for one reason—they become smaller by using, like the grindstone; and there are jobs where it is desirable that the emery wheel should retain its original and uniform size. It is well, therefore, to give a few words of this almost forgotten shop lore. The emery wheel should be of soft wood—pine is to be preferred—made of alternate layers of boards planed to make good joints, put together with glue and screws, the grain crossing each alternate layer of boards, which should be not more than ¾in. thick; ½in. boards are better. Make the wheel slightly thicker than it is to be when finished, as it is to be turned and trued on the sides as well as the face. With a band saw or gig saw, shape the glued up and screwed boards to a circle, chuck it in a lathe, and bore and turn a hole and recess at the centre to receive a disk, or gland, of iron that has been bored and faced up, having screw holes in its flange. The hub of the gland should be seated in the wooden wheel. When the gland is in place and secured the wheel is ready to be turned to finish. It is mounted on an arbor for this purpose. Some wheels are to run on a threaded arbor, and the gland is therefore threaded. After turning to size, peg a belt or band of wet belt leather with shoe pegs to cover the rim of the wheel, flesh side of the belt outside. This makes a hard wheel. If one with a yielding surface is desired, peg on layers of Canton (cotton) flannel to the requisite thickness, carrying them over the edges of the face to make a round edge. Cover the whole, not with leather, but with strong denim or bed ticking, pegging or tacking it on the sides of the wheel. This makes a soft or stuffed wheel, which is for polishing—not grinding—and it will do work of a somewhat irregular form. Brush the face of the wheel with hot glue, pass a round bar through the centre and roll the wheel in emery that is spread in a shallow trough or on a clean table. Any particles of iron or steel filings in your emery will make trouble; have the table or cloth very clean. One coating of glue and emery is better than more, for when the outer coating is worn off the glue will glaze. Do not rap off any of the loose particles of emery until the wheel is perfectly dry; the reason is obvious—the undried glue will not hold the particles in place. When the wheel has been worn, the glue and emery are removed by soaking in water, and the facing repeated. If the use of these wheels is insufficient to warrant the trouble, it is well to have a trough of water, in which two iron rolls revolve by power, the faces of the rolls far enough apart to allow an emery wheel to roll and ride between them, the shafts of the rolls to be connected at one end by gear wheels and an intermediate, so that they both turn in the same direction, and the emery wheel standing on its face will be slowly revolved by their combined action, the water in the trough being at a sufficient height to just wet the face of the wheel as it turns. This method prevents the whole wheel from being wet and warped. If this method is not feasible, repeated hand washings of the face must be made to soften the glue.—*Southern Coachmaker.*

## PHOTOGRAPHING INTERIORS.

IN some occasional notes for beginners contributed to the *Photographic Times*, "Flandreau" writes thus about photographing interiors:—

In making negatives of interiors the circumstances are quite different from those under which landscapes are photographed. Not only are the circumstances different, but so also is the resulting negative, especially as regards its characteristics of chiaro-oscuro. However beautiful shadows and violent contrasts may occasionally be in landscapes, in negatives of interiors they are not to be desired. We must here be content with composition alone for artistic beauty, and should not employ lighting as a means to that end. Perfect detail is most desired, and a negative showing well the delicate tracery of carpet and wall paper, and reproducing distinctly the details of furniture, familiar portraits and other objects in the room should always be aimed at. Such a negative can only be made by the employment of a small diaphragm in the lens, and by giving an ample exposure; this latter being of the utmost importance. A beginner is far more likely to under-expose than to give too long a time to his plate. It is comparatively easy to check the development in the case of over-pressure, and to produce an excellent negative, while an undertimed plate is hopeless, for if urging be resorted to by increasing the strength of the developer, fog will be the inevitable result. Let the novice, therefore, be on his guard and give a liberal exposure when photographing interiors.

It is a mistaken idea held by some that to exclude all strong light conduces to the development of detail in the negative. Now, this method has but one effect upon the result—the making of a longer exposure necessary. Admit all the *diffused* light possible, and make the exposure when the subject is best lighted. All *direct* sunlight must, however, be carefully excluded, as this would so unequally affect the film that parts of the resultant negatives would be much too dense, while on others no detail at all could be discovered. A plain white linen curtain, or even white paper placed over the window through which the direct sunlight comes, will successfully diffuse it. It is best, so far as possible, to light an interior from the sides and from behind the camera, and in order to do this, that time of day must be selected for the exposure when the greatest amount of light will come through the side and rear windows.

It is scarcely necessary to add that a wide-angle lens should be used. One with as short a focus as will clearly cover the entire plate will include the maximum amount of the interior. The longer the focus the less will be included in the field of view, but with a relative increase in the size of individual objects.

## USEFUL AND SCIENTIFIC NOTES.

**Coal and Iron.**—The consumption of coal in the iron manufacture of the United Kingdom, relatively to the total production of pig iron, as compiled from the "Mineral Statistics of the United Kingdom" has been reduced in the past few years. The figures, so far as they go, would appear to show that the average quantity of coal consumed per ton of pig made in the United Kingdom as given in the British Iron Trade Report, by Mr. Jeans, was 2·08 tons in 1883, against 2·55 tons in 1874. In the interval, therefore, the quantity of coal used per ton of pig was reduced by very nearly half a ton over the whole—thanks very largely to the more general adoption of the Cowper and Whitwell hot-blast stoves.

**The Cotton Plant.**—A contemporary says Mr. A. A. Luber, of Macon, Georgia, has succeeded in endeavours to hybridise the cotton plant that grows wild in Florida with the common okra. The plant has an average height of 2ft., and each plant ha only one large bloom. Each boll is said to produce about 2lb. of very long-stapled cotton. There are no seeds in the lint, from four to six seeds, resembling those of persimmon, being at the bottom of the boll. If this is true, the new cotton will need no ginning, and the effect must be felt in several parts of the cotton industry if the new plant can be commercially cultivated.

**Shaving a Luxury.**—We do not believe it ourselves under any circumstances, being tender skinned; but are ready to admit that one of Messrs. Heaton and Co.'s hollow-ground razors, which they have sent us, and which they supply post free for 1s. 8d., brings it as near as is practicable. The temper and finish of the razors are very good.

# SCIENTIFIC SOCIETIES.

## ROYAL METEOROLOGICAL SOCIETY.

THIS Society opened its sixth annual exhibition of instruments on Wednesday, the 18th inst., at the Institution of Civil Engineers, 25, Great George-street, S.W. This exhibition is devoted to sunshine recorders and solar and terrestrial radiation instruments.

The first attempt at obtaining an instrumental record of the amount of sunshine was made by Mr. J. F. Campbell, of Islay, in the year 1854, when he mounted a hollow glass sphere filled with acidulated water in the centre of a cup of mahogany, so arranged that the sun's rays were focussed on the interior of the cup and burned it. The lines of burning, therefore, indicated the existence of sunshine. Solid glass spheres have been substituted for the hollow ones, and cards in metal frames have replaced the wood; but in its principle the sunshine recorder of 1885 differs little from that erected on Richmond-terrace, Whitehall, thirty years ago. Other modes of recording sunshine are based on the action of the rays of the other end of the spectrum on the actinic instead of the heat rays. Among workers in this direction may be mentioned Marchand, of Fécamp, Sir Henry Roscoe, and others. The most recent improvements in this direction are those by McLeod and by Jordan.

With regard to solar radiation thermometers, the successive stages in the assumed perfecting of these instruments have been as follows:—An ordinary mercurial thermometer acts as a spherical mirror, and reflects the rays which fall upon it. To lessen this, the bulbs were first made with black glass; moreover, originally the degree marks were put upon the supporting slab, then they were put upon the tubes of the thermometers. It was then found that in a position where two thermometers with similarly coated bulbs were exposed to the sun—but one was exposed to more wind than the other—the indicated temperatures varied greatly. To avoid this it was proposed that the thermometer should be inserted in a glass shield exhausted of air. Various forms of mounting have been adopted; but the chief efforts have been expended in determining the influence of the amount of air left in the so-called vacuum. The next stage was that, inasmuch as black glass had a bright-surface, there was still much light reflected, and therefore the surface was dulled with a coat of lampblack, so that all heat falling upon the bulb might be absorbed. Subsequently, owing to the influence of the lower temperature of the unblackened thermometer tube, about 1in. of it was coated like the bulb. As evidence of the degree of exhaustion, a small mercurial pressure gauge was attached to the thermometer; and by other makers platinum wires were soldered through the shield, so that the stratification of the electric are might indicate the amount of air still left.

With regard to terrestrial radiation thermometers the pattern of instrument used has varied very little. The Rutherford minimum has almost always been used, but its sensitiveness has gradually been increased. The spherical bulb was replaced by a cylinder; the cylinder was elongated and bifurcated, and eventually, in order to strengthen the forks, they were united into what is known as a "link." Another plan was to flatten the cylindrical bulb into as thin a plate as possible, this giving a maximum of surface in proportion to the contents. The bulb was also made double, and thus we have the so-called "bottle" pattern, and then the tube was led into the side of the bottle, and both ends of the bottle were left open, and so we have the "open cylinder"—a remarkable specimen of glass blowing. Then there have been two patterns of mercurial thermometers, Casella's and Negretti's. Difficulties have arisen from the degree marks being obliterated by the weather. To guard against this, the tube has been inclosed in what are known as Leach's shields, and many attempts have been made to render the joint at the entrance of the tube watertight. This is not easy, because the thermometer is exposed to a great range of temperature, and the air inside the shield varies so much in volume that it forces its way through almost every joint. The object is, however, effected when the external jacket is sealed on the stem near the bulb.

In addition to specimens illustrating the various patterns of the above instruments, the exhibition also included a number of new instruments and many interesting photographs, sketches, and diagrams. The photographs of clouds and lightning were very good.

At the meeting of the Society the President, Mr. R. H. Scott, F.R.S., read a paper giving a brief account of the various instruments and arrangements to be found in the exhibition for the purposes of recording solar and terrestrial radiation, and the duration of sunshine both in regard of its light and its heat, the last-named being obtained by means of the sunshine recorders, which are now pretty generally used. He exhibited 12 monthly maps showing the percentage proportion of hours of recorded sunshine to the hours the sun was above the horizon in the various districts of the United Kingdom. He stated that the features which strike anyone on examining the maps of sunshine, which are, for the most part, for the last five summers and for the last four winters, excluding January to March, 1885, which has not yet expired, are—First, The broad fact that the extreme south-western and southern stations are the sunniest, as has already frequently been pointed out. Jersey is undoubtedly the most favoured of our stations in this particular. Second, That in the late autumn and winter Ireland is much sunnier than Great Britain, Dublin having absolutely the highest percentage of possible duration of sunshine in November and December, and being only equalled by Jersey in January. The Dublin instrument is not situated in the city, but at the Mountjoy Barracks in the Phœnix Park, beyond the viceregal lodge. The north-east of Scotland is also exceptionally bright, as the station, Aberdeen, lies to leeward of the Grampians. In April the line of 40 per cent. of possible duration takes in Jersey, Cornwall, Pembrokeshire, the Isle of Man, and the whole of Ireland, except Armagh. The absolute maximum of the year occurs in May, and the amount rises to 50 per cent. (nearly to 60 in Jersey) over the district just mentioned as enjoying 40 per cent. in April. In June there is a falling off which is continued into July, and even into August in the Western Highlands. In the South of England, however, a second maximum occurs in August, the figure for Jersey rising to 50 per cent. This is mainly due to the exceptionally bright weather of August, 1884, in the Southern Counties of England. In September Ireland shows a falling off, and the greatest degree of cloudiness is in Lincolnshire. In October the Midland Counties of England are the worst off. In November the line of 40 per cent. incloses two districts, one Dublin, already mentioned, the other the Eastern Counties (Cambridge and Beccles). The absolutely highest monthly percentages in the period under consideration are in the month of May, 1882, in which St. Anne's Head, Milford Haven, had 62 per cent., while Geldeston (Beccles), Douglas (Isle of Man), and Southbourne (Bournemouth) show 61 per cent. The exhibition remained open till the 20th instant.

# DOMESTIC RECIPES.

**Macaroni (Italian Style).**—The *Caterer* gives the following as an approved recipe: Take six ounces of Italian macaroni, and put it into a stewpan with three pints of water, adding salt and pepper, a saltspoonful of each. Place the saucepan over a gentle fire, and, when the contents have simmered for twenty minutes, drain the water off thoroughly, and then add to the macaroni one half-pint of good broth. Replace the saucepan on the fire, and let the contents again simmer until all of the broth has been absorbed. Now have some grated cheese—the Parmesan and Gruyère mixed in equal proportions are best for this purpose—and add two ounces of it to the macaroni: when it melts, add two ounces more, together with one ounce of best butter, giving the pan a circular motion in order to mix the melted cheese thoroughly with the macaroni. Then serve on a hot dish.

**False Rabbit.**—The same authority gives these directions for a favourite German dish: Chop as fine as for croquettes one pound of the lean of beef, and one pound of the lean of fresh pork, and mix them together. Add four raw eggs, a tumblerful of sifted bread-crumbs (better than cracker-crumbs), half a small nutmeg grated, two teaspoonfuls of black pepper, a tablespoonful of salt, a small onion, parboiled, and minced very fine, a little chopped sweet savory, parsley, and thyme, in quantities to suit the tastes. Knead into a loaf, in flat, roundish form. Roll the loaf in egg, then in bread-crumbs, and place it in a dripping-pan, with a small piece of *salt* pork on top of it, sliced like the pork placed on top of baked beans when served. Place the pan in the oven, and with the drippings from the pork occasionally baste the loaf. Its being cooked can easily be tested by prodding it with a carving-fork. When done, it is a good dish served hot. When cold, it is better still—a sort of sublimated sausage, as toothsome as any preparation that ever came from the shop of a *charcutier*, and excellent as a relish for luncheon or tea.

THE total quantity of pig iron produced in the United Kingdom during 1884 was 7,528,966 tons, being a decrease of 961,258 tons, or 11 per cent. on the quantity made in the preceding year. This is the second year during which a decrease of production has occurred since 1879. In 1883 the decrease was 3,063 tons on the make of 1882. In 1879 the make was 290,566 tons below that of 1878. But on comparing the latter year with 1884, it comes out that the increase of make in the interval has been 1,519,532 tons, or 25 per cent.; so that, on the whole, substantial progress has been made.

# SCIENTIFIC NEWS.

THE death is announced of Theodor von Frerichs, the famous Berlin professor, and the foremost exponent of clinical medicine in Germany. He was born at Aurich in 1819, and after studying chemistry and physiology, turned his attention to clinical medicine, in which he became so famous that he attracted students from all parts of the world. A year ago the University of Berlin celebrated the 25th anniversary of his professoriate.

M. Joseph Alfred Serret, professor at the Collége de France, and Member of the Bureau des Longitudes, fell down dead in Paris last week. He was born in 1819, and was admitted a member of the Academy of Sciences in 1860.

The retirement of Mr. Walter White from the post of assistant secretary to the Royal Society will be regretted by the majority of the Fellows. The post is one requiring much tact and unwavering courtesy, and during forty years Mr. White has accomplished his duties in such a manner as to earn the good wishes of all the Fellows.

Dr. Bouchardat, Professor of Hygiene at the Paris Faculty of Medicine, has, after a service of nearly forty years, retired, and his name has been placed on the list of honorary professors.

Herr von Gothard contributes to the *Astronomische Nachrichten* an elaborate paper on the changes observed in the spectrum of Beta Lyræ during the past year. The changes are believed to be periodical, and observers are requested to direct attention to the star. Herr von Gothard made 30 observations between the middle of February and the middle of November, and found the bands $D_3$ to periodically vary from an almost dazzling brightness to total disappearance.

We have received a copy of the Meteorological Observations for 1884 taken at Rousdon Observatory, Devon, near Lyme Regis, Dorset. The observatory is situated 524ft. above the sea-level, and has a good exposure on all sides. Observations, such as these, made at a few well-equipped stations in different parts of the island would, on comparison, soon teach us more than we have learnt hitherto about the weather. The observatory belongs to Mr. Cuthbert E. Peek, M.A., F.R.A.S.

Dr. R. C. Kedzie sends to the *New York Tribune* an explanation of the discrepancy in thermometer readings taken simultaneously at places within the vicinity of one another. He says "We treat of air under the head of pneumatics, whereas it sometimes comes rather under the head of hydraulics, for cold air flows in currents, the same as fluids. In the absence of wind, which mixes up the strata of air of different temperatures, and consequently of different specific gravity, the cold air of the night will flow in streams, and gather in ponds or lakes the same as water. Under such circumstances the temperature will vary with the level." Near Dr. Kedzie's laboratory a ravine runs through the College lawn, and thermometers placed at the laboratory door, and in the ravine 25ft. below, indicated on Feb. 22, 6.45 a.m. — 15° at the laboratory and — 20° at the ravine. This difference of 5° was observed on the following morning, the temperatures being the same, although the lowest reading during the preceding nights at the meteorological station, 40 rods distant and on higher ground than the laboratory, was — 14°. The thermometers were changed about, and gave corresponding readings; but it is not quite clear what is meant by — 15°, whether fifteen degrees below freezing-point or fifteen degrees below zero—presumably the thermometers were graduated on the centigrade scale.

At a recent meeting of the Linnean Society Dr. F. Day read a paper on the rearing, &c., of salmon in fresh water, in which he described the experiments of Sir James Maitland at Howietoun. In December, 1880, salmon eggs and milt were obtained from fish captured in the Teith, and the ova were hatched in March, 1881. In November, 1884, ova were obtained from one of the young salmon, and milted from a Lochleven trout. On Jan. 23, 1885, eighteen of the eggs hatched, and the fry were strong and healthy. Pure salmon eggs have also been hatched, the young being reared to parr, smolts, and grilse, and salmon have been successfully hatched from their ova. It remains to be seen how the fry thrive in fresh water.

The collections belonging to the Science Department at South Kensington Museum are to be reported upon by a committee who are also to consider plans for properly housing them. Sir F. Bramwell is chairman, and Dr. W. Pole secretary.

The Imperial Geographical Society of Vienna have resolved that Dr. Lenz should be sent to explore the watershed between the Nile and the Congo.

At a recent meeting of the Physical Society Mr. C. Cleminshaw described some "Further Experiments on Spectrum Analysis"—viz., methods of obtaining the inversion of the sodium line in the spectrum of the limelight. The first consisted in concentrating the rays from the slit by a lens, just beyond the focus of which is a spoon in which sodium is ignited by a Bunsen flame. In the second method the burner and sodium are introduced between the lime and the slit, and carbonic acid is introduced into the flame. The result in either case is to cause the inversion of the D line. Prof. Guthrie, alluding to the pale blue flame produced by common salt in a coal fire, suggested that there might be more than a mere mechanical action produced by the carbonic acid. Mr. Cleminshaw, however, believed that the action was purely mechanical.

M. B. de la Grye is going to Teneriffe in order to study the laws of gravitation under all the conditions for which the peak offers facilities. His observations are to be reported to the Minister of Instruction.

# LETTERS TO THE EDITOR.

*[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.]*

*All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, 332, *Strand, W.C.*

*All Cheques and Post-office Orders to be made payable to* J. PASSMORE EDWARDS.

⁂ *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks a vice from whence great inconveniences derive their original." —*Montaigne's Essays.*

◆

## ENCKE'S DIVISION IN SATURN'S RING—THE PRIMITIVE STATE OF MAN — MAGNITUDES OF SMALL STARS—FULL MOON IN FEBRUARY, 1904—A NEW FORM OF OCCULTATION—MAKING AN ASTRONOMICAL TELESCOPE.

[23998.]—IN connection with letter 23919 (p. 31). I may remark that while drawing Saturn at the telescope during the first week in March, I could not divest myself of the impression that ring A was striped with several concentric fine lines, or divisions, parallel to its edges. I cannot doubt, however, that this was an optical illusion. My supposititious divisions were of hair-like tenuity, and all seemingly alike. I may reiterate here that I have on rare occasions held Encke's division steadily for some seconds at a time with my 4⅛ Dallmeyer achromatic, and of this I have no doubt whatever.

Mr. John Hampden (letter 23925), "Otter" (letter 23926), and "J. H." (letter 23927), all on p. 31, beg the entire question of the authorship of the Pentateuch. As for Mr. Hampden's "testimony of the highest authorities of the last 6,000 years," how can any human being *testify* to what he has never seen? It is to be hoped that the next time Mr. H. finds himself in the witness-box, he will not attempt to offer such "testimony" to the Court, or he will be pulled up very summarily indeed. With reference to "Otter's" quotations from Exodus xx. 11, I can only say (with "O. J. L."), "*If* Moses gave to Israel the Ten Commandments," he was assuredly not consistent in the reasons he alleged for the observance of the seventh day (Cf. Exodus xx. 11 and Deuteronomy v. 15). As for "J. H.," his boldness in attempting to instruct any human being in geology is amazing. He is hopelessly mistaken in his notion that "during geological times climatic changes were produced by *the internal heat of the earth* and *not by the sun*," if, by "geological times," he intends to signify those of which the records are preserved in the rocks. The sun must have shone on the Cambrian trilobites, just as he does now. Did "J. H." ever see a trilobite's eye? There have, moreover, been glacial epochs in all stages of the earth's history (*vide* "Ramsay's Physical Geology and Geography of Great Britain"), and, what is of vital importance to our present argument, *man himself was pre-Glacial.* With regard to the *Christian Million*, I thought that its utter untrustworthiness in anything relating to science was too notorious for anyone to have had the hardihood to quote that; but seemingly "J. H." takes its utterances for gospel, his own knowledge of the rudiments of his subject being too imperfect to enable him to check its assertions. Let me recommend "O. J. L." to obtain and read Joly's "Man before Metals" in the "International Scientific Series," published by Kegan Paul, Trench and Co. He will find the subject of primitive man discussed there upon the sole basis upon which such discussion can take place at all. I mean the scientific one. [Since the above was written, I have seen the various letters on this subject in the ENGLISH MECHANIC of to-day (March 20), with reference to which I would append a few remarks. Imprimis with regard to the letter (23972) of "O. J. L." himself, on p. 60, I may say that "the glaciation which may have wrecked our world" is a mere figment. That all Europe was glaciated in the Pleistocene age, is as certain as that I am writing; but that such glaciation extended, say, to the Sahara is a perfectly unwarranted and unwarrantable assertion. One of the most curious mistakes into which people either ignorant, or possessing merely a smattering, of geology fall, is to assume that the various "formations" surround the globe like the coats of an onion, and that, for example, Oolitic rocks were simultaneously deposited, and an identical fauna existed, in what are now Somersetshire and the Transvaal. The glaciation of the northern and southern hemispheres certainly occurred at vastly different periods. In plain truth, glaciation has happened in every stage of the earth's history of which we possess visible records: even at that almost appallingly remote period when those who are so burningly anxious to prove that the sun never became visible until "the fourth day" assert that the earth was nearly red hot! Turning now to letter 23982 (p. 62) I should like to ask "Arvonia" one question: "If, indeed, the Book of Mormon was not revealed to Joe Smith and copied by him from the plates of gold in the year 1827, when could the hundreds of thousands of 'Latter Day Saints' now existing have been persuaded to receive it?" To "J. S. B." (letter 23984), C. J. B. Findon (letter 23988), "E. C. C." (letter 23989), and "K." (letter 23990), p. 63, I would say that I do seem to have given Methuselah an undue advantage, inasmuch as he appears only to have been contemporary with the Flood—and not necessarily to have survived it. If, however, any proof of "the mythical character" of the entire set of legends were needed, it might well be found in the alleged ages of the subjects of the quoted pedigrees. This superstition of the great age, and the cognate one of the gigantic size of their primitive fathers exists among all races emerging from barbarism. Would Mr. Findon be surprised to hear that my familiarity with the book I quote is, at the very least, equal to his own? I, however, certainly consider Bibliolatry as degrading and enslaving a form of idolatry as can be practised. To "K." I would say that the word "begat" is quite obviously used in the sense of the recording the time of birth of the person to whom it is applied.]

In reply to "H. A." (query 56119, p. 43), there are several formulæ for determining the magnitudes of stars visible with any given aperture in inches. Carrington, adopting 2·75 as his light ratio, $m = 9$ mag., and $a =$ 1in., gave the following one for determining the magnitude of stars *just* steadily visible with no moon in a dark field, with any given aperture.

$$\tfrac{1}{2}\log. R = \frac{\log. A - \log. a}{M - m}.$$

This would give—

| | | | | inch. |
|---|---|---|---|---|
| 6 | mag. | just certainly | visible with | 0·22 |
| 7 | ” | ” | ” | 0·36 |
| 8 | ” | ” | ” | 0·60 |
| 9 | ” | ” | ” | 1·00 |
| 10 | ” | ” | ” | 1·66 |
| 11 | ” | ” | ” | 2·75 |
| 12 | ” | ” | ” | 4·56 |

Pogson's very simple formula is founded on an assumed light ratio of 2·512, and is this: If the observer will determine for himself the smallest of Argelander's magnitudes, just discernible by fits on a fine moonless night, with an aperture of 1in., and call this quantity L (or the limit of vision for 1in.); the limit $l$ for any other aperture is given by the simple formula, $l = L + 5 \times \log.$ aperture. Pogson found, from a large number of experiments, that L was = 9·2 (for his own sight), and if we are content to accept this as our standard, we have only to multiply the logarithm of the aperture of our telescope by 5, and add 9·2 to the product, to obtain the magnitude of the smallest star visible with that aperture. One example must suffice. What is the smallest star visible with an aperture of 0·23in.? The log. of 0·23 is $\overline{1}\cdot361728$, and if we multiply this by 5, we get $\overline{4}\cdot808640$. If to this we add 9·2, we obviously obtain 6·0, so that the 6th mag. is the *minimum visibile* for an aperture of 0·23. With Carrington's light ratio, this, as we have just seen, comes out 0·22. A collation of Argelander's magnitudes with others in use will be found on p. 207 of "Celestial Objects for Common Telescopes."

"Leo" (query 56131, p. 43) may attack his own problem thus: Note that 1900 is *not* a leap year. Hence from March 1st, 1885, to March 1st, 1904 is 15 common years, three leap years, and 61 days, i.e., 15 × 365 days + 3 × 366 days + 61 days = 6,634 days. But a synodical lunar month = 29·5305887 days, so that we have only to divide 6,634 by 29·5305887 days, to ascertain that on March 1st, 1904, the moon will have passed through exactly 224·6485 lunations. Hence there will be a full moon in February in that year. The Metonic Cycle of 19 years is, of course, only an approximate one, which does well enough for the idiotic ecclesiastical Paschal moon, but is inapplicable in a case like this.

An absurd misprint occurs in lines five and six of column three on p. 53, where the President of the Liverpool Astronomical Society is represented as saying that Dr. Copeland of Dunecht had called "his attention to the Occultation of Jupiter's II. satellite by its own shadow on the night of February 19" (!). The American gentleman who lifted himself by the waistband of his own trousers was as nothing to this. What, of course, Dr. Copeland did see was Satellitte II. superposed on its own shadow on the face of the planet.

Mr. F. Shakespear (query 56161, p. 68) must buy a 3½in. object-glass, as he cannot possibly make an achromatic one of that size (or, for the matter of that, of any other) himself; and a non-achromatic one he would find rather worse than useless. If the focal length of his objective is 54in., an eyepiece composed of two plano-convex lenses, the field-lens ·864in. focus, and the eye-lens ·288in. focus mounted ·576in. apart, with their convex sides towards the object-glass, will give him a power of 125. A diaphragm must be inserted at the focus of the eye-lens.

**A Fellow of the Royal Astronomical Society.**

## A POSSIBLE CASE OF PROPER MOTION IN A NEBULA.

[23999.]—CASES of proper motion in nebulæ are of such rarity and interest that it may not be out of place to call attention here to what seems to be a fairly well attested instance of motion in a small nebula. The object in question is the triple nebulous star No. 2529 of Sir John Herschel's fifth Catalogue of Double Stars, No. 705 of the Catalogue of Nebulæ published in the "Phil. Trans." for 1833, and No. 2091 of the General Catalogue. It will be most convenient to give the principal observations at length in chronological order.

The object in question is entered in the fifth catalogue thus (I have added the letters A, *a*, B, and C for convenience sake), the distances being estimated only.

[A − *a*] 95·3° : 1½″ : 11, 12,

"A most curious, delicate, and interesting object. The nucleus of a very faint nebula, examined with 320; proves to be distinctly a 1st class double star." (Sweep 243).

[A − B] 10·8° : 7″ : 11, 14,

[A − *a*] 95·4° : 1″ : 11, 12,

"A nebula strongly suspected about the close double star, and a fourth star also suspected." (Sweep 242.)

[A − B] 8·0° : 7″ : 10·11, 13,

[A − C] 330° ± : 6″ : 10·11, 14·15.

[A − B] 7·0° : 18″ : : 10, 11,

"A double star in a very faint nebula. (A hurried observation.) The dist. seems to have been greatly overrated." (Sweep 338.)

[Sweeps 242 and 243 were made on the 23rd and 24th of March, 1830; Sweep 338 on April 6th, 1831.]

A little further on Sir J. Herschel writes of this object:—"Hardly less interesting, though much less conspicuous (being, in fact, one of the most difficult objects in the heavens) is *h* 2529, where a minute and very close double star forms the nucleus of a small round nebula. One or two other small stars in the immediate vicinity seem unconnected with it; but the exactly central position of the double star strongly points to a physical relation between them."

It will be observed that there is a great difference between the estimates of the distance of A − B in 1830 and 1831. Sir John thought the estimate in the latter year in error; but the estimates in sweeps 242 and 243 are really in fault. The mirror was very badly tarnished in March, 1830, and we see from Sir John's estimates of *h* 166, 128 (222 Cancri), 199, Σ. 1556, Σ. 1792, &c., on these two evenings in March, 1830, that, owing to the state of the mirror or some other reason, the distances were all largely underestimated. Judging from his observation of *h* 2616, the mirror was either out of adjustment or the definition very bad during sweep 243.

The angle of A-C should evidently be 230°±, not 330°±; a similar misprint has occurred in position angle of $\alpha^2$ Cancri in this very sweep, where 224·3° is evidently misprinted for 324·3°.

The next observation in point of time is one made at Parsonstown, on March 3rd, 1851, where the entry stands, "Double star with nebula north." In the recent publication of the nebula observations in the "Scientific Transactions of the Royal Dublin Society" the words—or rather the abbreviations of the words—"small, elongated, brighter in the middle," are added.

The late Professor d'Arrest observed this nebula with the 11·lin. refractor at Copenhagen in 1864 and the following year. He writes, *April* 8, 1864: "A double (?) star of the 10·11 magnitude, to which a short and shining tail is affixed. The nebula is prolonged towards the north; a very delicate nucleus at times shines through. The place is that of the fixed star; for the seeing at this time had become very indistinct, and so the components were not clearly divided. *February 4th*, 1865.—A double nebulous star. The stars are of magnitudes 10, 11, and 14. With a brilliant moon I see the nebula distinctly enough. A nucleus seemingly composed of many little stars seems an evidence of resolution; but I am not altogether certain of this. *March 16th*, 1865.—A triple nebulous star, arranged in this fashion. An 11-magnitude star south preceding [A]; this itself is composed of two, having a 15-magnitude *comes s.p.* [C]; a 13-magnitude star *n.f.* at 12″ distance [B]. This latter is situated in the centre of a small and faint nebula, so that the brighter star just spoken of [A] adheres to its edge. This star only appeared double in Lord Rosse's telescope in 1851. Herschel II. saw it at once triple."

Two recent observations at Parsonstown are given in the "Scientific Transactions" of the Royal Society of Dublin:—

"1872. April 2nd.—9 mag. star to nebula 13·0° : 19·7″. [A to nebula]. [angle — 180°].

"1872. April 2nd.—9 mag. star to 12 mag. star, 234·3° : 8·8.″ [A-C.]

"1876. March 22nd.—Double star [A--*a*]; star 10·11 magnitude, south [C]; and star 15·16 magnitude north, position 5·0°, distance 21″ [B], with very faint nebulosity around it, elongated suddenly towards the north."

Mr. Burnham gives his measures of the relations between A and the nebula on page 270 of Volume XLVII. of the "Memoirs" of the R.A.S. These are:

8·3° : 18·96″ : 10 (12) : 1879·225
7·5° : 18·96″ : 10 (12) : 1882·195

He quotes the first observation of Herschel (sweep 243), and says: "This note would seem to indicate the closer pair was the nucleus of the nebula, and not the 14 mag. companion. However this may be, the nebula is now 19″ from the principal star [A]. As this angle agrees substantially with H., and his distance is only estimated, there is no reason for suspecting change. I could not see any signs of duplicity in the 10 mag. star [A]; but the conditions were not particularly favourable. There is an excessively faint star [C] about 8″ from A in the direction of 230°, noted in my first observation. On the second occasion the seeing was too poor to show it. This may be the star suspected by H., although the direction is different. I am not prepared to say that the principal star is not double; but, if so, it must be closer than 1½″...... I have estimated the nebula as equivalent to a star of 12 mag., and it should, therefore, be apparent as a nebula with a comparatively small aperture." Mr. Burnham has accidentally overlooked the fact that this nebula is included in the catalogue of 1833 and the "G.C."

We see that in 1830 and in 1831 the close pair A was *exactly in the centre* of a small round nebula; in 1851 and 1865 it was *not in the centre, but on the s.p. margin* of the nebula, and the nebula had had moved so that a star B at. 21″ distance from A was then in the centre; from 1872 to 1882 the nebula was 19″ *distant* from the close pair A. Motion seems certain; but of what character is hard to determine. The star C is evidently variable. A very faint object in H's. reflector in 1830, D'Arrest rates it 11mag. of Herschel's scale in February, and 15 mag. in March 1865. It is called 12 magnitude at Parsonstown in April, 1872, and 10½ in March, 1876; is "excessively faint" in the 18½in. at Chicago in March, 1879, and invisible in 1882. The place of this nebula, brought up from the "G.C.," is for 1885·0, Xh.17m.35s.+13° 8·1′. It will be easily found by setting the telescope 36½′ to the north of Regulus, and then sweeping 15 minutes 20 seconds of time to the east. I trust that some of the readers of the English Mechanic who possess telescopes of sufficient size will examine and report on the present state of this curious object. Observations of such phenomena, carefully made, would be infinitely more valuable than merely looking to see whether the faint stars of the Trapezium of Orion, the Satellites of Uranus, or cognate objects, were or were not visible in the observer's telescope on some particular evening.

March 19th. **H. Sadler.**

P.S.—This nebula is shown on Peters's star maps to the north of A, but the scale is too small to show any detail. It does not appear to have been observed by Schönfeld, Schultz, Vogel, or by anyone except Sir John Herschel, the Parsonstown observers, D'Arrest, and Burnham.

## MIRA CETI—DOUBLE STARS.

[24000.]—The star near Mira Ceti, referred to by Mr. Ruthven (letter 23892, page 10), is not in any way connected with Mira itself. The following are some measures of the relations between these two objects:

Ḣ. 92·5° : 114·6″ : 1782·7.
Σ. 88·6 : 114·3 : 1820·0.
O.Σ. 85·2 : 115·6 : 1852·0.
β. 82·4 : 116·0 : 1879·5.

The change is due to the proper motion of the variable star, 0·23″ in 184° annually. ζ (Zeta) Tauri I do not know as a close pair. There are two 10-mag. stars north of it, for one of which P. Rosa found 347·0°, 176·7″, 1856·1; but this star is entered in the fourth edition of "Celestial Objects," because of the curious curved row of stars and Chacornac's strange variable nebula in the preceding portion of the field. 80 Tauri is too difficult an object now for Mr. Ruthven's aperture; for O. Σ. 98 Mr. Perry gave 203·5°; 1·03″ 1884·10. The pair *n.f.* this last is entered in error in Webb in this place (Cf. *Knowledge*, January 4th, 1884). It is really *n.* of ι (Iota) Orionis, and is formed of Nos. 719 and 725 of Bond's catalogue of stars near the nebula of Orion. According to Bond there is a 13·1 mag. at 37″ *f.* the pair nearly on the parallel, which Mr. Ward has not noticed. "Bright star *s. p.* δ Tauri" I cannot identify, unless it is Ḣ's *comes* to δ (IVh. 18·6m.+17° 38′) at 233° : 77″. The pretty little triple *s.f.* 135 Tauri must be that interesting pair So. 503; at least, I can find no other near, and the bright white pair near it would then be σ 210. For So. 503 (Vh. 49·4m. + 13° 56′) we have—

So. 134·1° : 39·95″ : 1825·1.
De. 120·0 : 8·08″ : 1873·9.
β. 82·6 : 2·90 : 1883·1.

Colours: deep yellow, deep blue. The faint star *s. f.* is at 158·8° : 24·6″ (Burnham), and, like the distant one at 334° : 234″, is fixed. The change in A B is due to the p.m. of A. For σ 210 De. has 130·4° : 45·66″ : 1875·0.

March 18. **H. S.**

## DOUBLE STARS, &c.

[24001.]—Σ. 1228, in Cancer, has a faint *comes* at 32″ ±, immediately *f.* the south star of the pair, making it triple. There are also two more pairs in the field of 6′ of Steinheil solid e.p. The fainter, and more distant, is 8″ and 70°, the second nearer is an unequal pair a little wider at 235°. Both pairs are *n.f.* Σ. 1228.

In same field with ι Cancri 5′ *n.p.* is a faint pair 30″ 360°. None of these are mentioned in Webb, either in connection with Σ. 1228, or ι Cancri.

Two of Jupiter's satellites formed a tolerably close pair at 11 p.m. on March 18, and at same time a very dark mark was visible on N.E. belt on the following side. This spot was about ⅓ on disc, and fell over towards the preceding side, as if its south point was in advance of base; a bright white spot preceded it in contact with it. A large, long white marking was visible on north side of S. E. belt, and several others preceding and following it. The larger one extended over one sixth of the disc.

**Edwin Holmes.**

## HYPERION.

[24002.]—The question of the visibility of the Satellites of Uranus has often been referred to in "E.M.," but very little has ever appeared as to Hyperion and Enceladus.

On Saturday, the 14th inst., at 8 p.m., I saw, following Saturn, at a distance of about 4′ to 4½′ of arc, a very faint star. As nearly as I could judge, it was in a direct line following, and was a very faint object indeed. I wish to ask if it is possible I saw Hyperion with a 9in. mirror in London?—e.p. was Steinheil's solid, power about 275. On the same occasion, Enceladus was easily seen between Tethys and planet, but not in a direct line between Enceladus, being further south, just off the *s.p.* end of ring. Dione was very faint, and hardly to be seen.

On the same evening, I found ξ Cancri close pair just divisible with 5in. stop. III. P. XI. easily seen with full aperture, as was also 2054 Draconis; and 175 Gemini just divided with 600. ω Leonis was two discs, but air was fluttery, and no clear view obtainable of this star. I judge the discs were in contact, however. What is the present distance of this star?

Allow me to direct attention to θ Aurigæ. I find this star very much more difficult than δ Cygni. Webb says 2·1″. Is this correct for present date? There are two faint preceding comes which are visible with 4in. stop, but the nearer one is much brighter than the more distant.

**Edwin Holmes.**

## TRANSIT OF JUPITER'S THIRD SATELLITE.

[24003.]—On March 20th I was watching the Transit of Jupiter's Satellite III., which entered bright at 10.24. After watching for half an hour I came to the conclusion that it was getting more faint, but could not decide whether it was owing to the satellite or to the greater brilliancy of that part of the planet. At 12.12 I again turned the telescope upon II., and saw the satellite black, as I find in my note-book, "like a drop of ink"; it was then past the planet's meridian. I compared it carefully with the shadow of Satellite I., which had entered upon the disc shortly before, and found it quite as black. Telescope 6in. equatorial reflector. **J. Ellis.**

## DARK TRANSIT OF JUPITER'S THIRD SATELLITE.

[24004.]—I was able to observe on March 20th, under more favourable conditions, a repetition of the phenomenon described in my letter (23953) on p. 55. I watched the third satellite enter upon the disc of Jupiter at 22h. 24m., and saw it bright upon the north red belt for about 10 minutes; it then remained invisible for about 20 minutes, when it reappeared as a faint grey spot. This gradually increased in darkness until it was almost as black as the shadow of the first satellite, which by this time was in transit. The outline of the third satellite was not so sharp as the outline of the shadow. Clouds came up soon after midnight, and prevented me from watching the egress. The first satellite, which crossed the planet a little north of the equator, was seen bright for 18 minutes after ingress, and was then lost to sight.

Shaftesbury. **T. Perkins, M.A.**

## THE SIX DAYS OF CREATION.

[24005.]—In letter 23985 Mr. W. J. Grey finds a difficulty in the 14th to 19th verses of Genesis i. He says, "According to verse 19 the sun was not made until the fourth day; that is, not until after the period to which 'J. H.' assigns geological time, but plants could not grow nor animals live without the sun." Now this was a great difficulty with me when I first began to read the Bible in connection with science; but as I became better acquainted with it I saw two important principles almost universally running through its accounts of things, which principles greatly helped me to understand the above difficulty. These principles are—1. Only so much as is necessary to faith and religion is described; all outside or beyond these, such as science, curious questions, and even history, are omitted, and left to the intellect and research of man, for which God has given him a mind well fitted, and as proper to be exercised upon as our hands are upon the work they are evidently intended to do, and are designed admirably to do, too. 2. The Bible describes facts as seen from man's standpoint—i.e., the surface of the earth—and in the ordinary language of man, without going into the science of the facts, which science would not have been understood by, nor of any use to, the persons the Bible was given to. Of course there are other broad principles in the Bible besides these two. I only mention these as bearing on the scientific explanation of the six days of creation. Keeping these principles in view, I will give what I believe to be the scientific explanation of Genesis i., and nothing else ought to be allowed in the "E.M.," which is a mechanical and scientific journal and not a theological one. Gen. i. 1 describes the absolute creation of the universe (the heaven and the earth) by God, the same as stated by Paul in Heb. xi. 3. That an interval is supposed between verses 1 and 2 is to my mind most clear, for I find it is the custom of the Bible to put the little word "and" between events that have many years between them; but this is rather a theological than scientific branch of the subject. After the creation of the heaven and the earth there comes a time when "the earth was without form, and void; and darkness was upon the face of the deep." How long this interval was we cannot tell—we know from science it must have been long enough for all geological periods; and how this chaotic state of the surface of the earth was brought about, whether by glacial or volcanic or any other course, is immaterial for the purpose for which Genesis was written (and therefore not here mentioned)—viz., to establish the faith and religion of God among the Jews. All the Bible states is that

God created the heaven and the earth they saw, and that at the commencement of the Adamic state of things the surface of the earth was in a chaotic state and darkness was upon the face of the deep. Whether this chaotic state of the surface of the earth was universal or only confined to the earth as known by Moses is not stated; it need not have been more than what Moses understood by the term earth, it may have been even less than that, only around Eden, the place where the race of men known to the Jews started from. Now, we can easily understand that the throwing of the earth's surface into a chaotic state would fill the atmosphere with such dense mist that no light would reach the place where man is supposed to be (the surface of the earth) describing and viewing what took place during the six days; and here comes into play the second principle I have mentioned above—viz., that everything will be described in the then ordinary language, as perceived, or seen, from the surface of the earth, man's proper place of observation, and not from the moon, or some distant planet, and with our modern scientific ideas, such ideas, though true, could not have been understood by the Jews, nor were they necessary to establish them in the faith of God as the only true God, and Creator of the heaven and the earth. In verse 3 we have, "And God said, Let there be light." This, in scientific language, means that the dense mist so far decreased in density that the light of the sun was perceived around the supposed spectator and describer; but the sun was not yet to be seen through the mist, and as the sun set this light would depart, and thus the first, or previous darkness, of verse 2 and the past light of verse 3—*i.e.*, "the evening and the morning"—"was the first day" (5v.).

In the sixth verse we have—"And God said, Let there be a firmament in the midst of the waters, and let it divide the waters from the waters." This, in scientific language, means that the dense mist was cleared away from or rose from the surface of the waters, and formed clouds above, and thus the firmament was formed, the firmament meaning the space where the fowls of the air fly (see verse 20). And thus the waters in the heavens—i.e., in the clouds—were divided from the waters on the earth (verse 7). Thus ended the second day. In verse 9 we have—"And God said, Let the waters under the heavens be gathered together into one place, and let the dry land appear." This, in scientific language, means that the waters subsided, or the land was upheaved, so that the dry land appeared, and on this the grass and herbs and trees were made to grow by God (verse 11). The clouds were still dense enough above to hide the face of the sun, though perhaps gradually clearing; and thus ended the third day. In verse 14 we have—"And God said, Let there be lights in the firmament of the heavens to divide the day from the night; and let them be for signs, and for seasons, and for days, and years." The scientific explanation of this is that the clouds by this time had broken up and cleared away, and thus left the moon as the predominating or ruling object of the night, and the sun as the predominating or ruling object of the day, and thus this "evening and morning were the fourth day." But some may say, "the moon and sun are not for signs and for seasons"; but this is judging of them by our customs. The book of Genesis was written for Jews, and with them at each new moon a most important feast was held; in fact, they watched for the first appearance of the new moon to know when to commence their feast; and, of course, the sun was for days, and seasons, and years—i.e., marking them out to the Jews also. Now, with the above easy and natural explanation we have not to suppose that the animals and plants before Adam and during the long geological periods had to live without the sun, or that light was created before the sun, we have only to look at all that is said as such by one using his eyes while occupying the natural place of man—viz., the surface of the earth—and describing in ordinary language what he saw as the work of God; to such a one the visible order of the phenomena would be the very order given in Genesis i. The fifth day was taken up in forming the fish of the sea and the fowls of the air, while on the sixth day the beasts of the field, and last man was formed. I do not here go into the question of how many thousands of years man has been on the earth, or how many orders of men have been, believing as I do that science has not definitely settled these questions concerning man's origin; when it has settled these questions, it will be quite time for us to compare its undisputed teachings with the Bible account, when I have no doubt they both will be as easily reconciled with one another as the fact that the sun had an existence long before the time referred to in Genesis i. 14. **H. A. Wassell.**

Addenbrook Villa, Love-lane, Stourbridge.

## THE STATE OF MAN.

[24006.]—"J. H.," in his very interesting communication, says that at the Glacial period "the world" became "desolate and *dead*." Now, I should like to know upon what facts he bases this remarkable statement?—as it is a well-known fact that the glacial effects only extended as far as the southern slopes of the Himalayas, and that the equatorial regions were not desolated by the cold. Also, even during the intense cold, an Arctic flora and fauna lived in *these* latitudes, of which the Arctic plants of the Alps, Pyrenees, &c., are the remnants. Many fossils are found which were living animals of various species and which lived through the cold ages of our earth's history.

In reference to man's presence, Geikie says—"There can be no doubt that he inhabited Europe after the greatest extension of the ice. He not improbably migrated with the animals that came from warmer climates into this continent during the interglacial intervals. But that he remained when the climate again became cold enough to freeze the rivers and permit an Arctic fauna to roam far south into Europe is proved by the abundance of his flint implements in the thick river gravels, into which they no doubt often fell through holes in the ice as he was fishing."

"J. H." refers to the statement that "darkness was upon the face of the deep," as if that proved his case; but it only shows that there was a deep. That *it* was inhabited is proved by fossil evidence. There is no evidence that I am aware of, proving, or even suggesting, that a great interval of darkness occurred at the time of the glacial period. The molluscs of that period were almost identical with those at present in existence, as nearly the whole of the species found in the Clyde basin still live in Scottish seas, though a few are extremely rare. They had eyes, and it is therefore clear that light must have been in existence. Has "J. H." any reasons to suppose that light was absent during the Glacial period?—if so, I should like to hear them, as I am not writing in reference to the general Scripture narrative, but only concerning "J. H's." peculiar theory of the Glacial period.

**C. J. B., Ventnor.**

[24007.—THIS subject divides into two parts—1st. The general statement respecting Creation, the Fall, the Deluge, &c. 2nd. The authorship and probable date of the whole or parts.

In my last I dealt only with a portion of the second part, and may add that the 1st chapter of Genesis, and the first three verses of the 2nd chapter are written by the Elohist, while the rest of the 2nd chapter, and the story of Adam and Eve are by the Jehovist. In examining Genesis I recommend your readers to mark with a pencil the parts where the word Lord (which ought to be translated Jehovah) occurs, and compare it with the rest, remembering that the whole has been combined by a third writer. The account of the *six* days of creation is not repeated by the Jehovist, who simply speaks of "the day in which the Lord created the heavens and the earth,"—an odd statement if, as "J. H." stated, the earth was created long before, and was only furbished up anew. This idea is flatly contradicted in the first set of Commandments, where it is said that, not only did God create "all that is" in the heavens and the earth in six days, but also the heavens and the earth themselves. We may dismiss "J. H.'s" idea as flatly opposed both to the spirit and letter of the text. It is argued that the second account is only a condensation of the first, and that the word "day" is used as a general term. This might be so but for the context, which says that "the Lord God had not caused it to rain upon the earth," so that the plants which had been placed in the earth *could not grow*; that surely points to a limited time, and, moreover, is in flat contradiction to the statement of the writer of the first chapter, that water covered the earth on the first day, as, if so, the ground would have been wet enough for the plants to grow without rain. The great point gained by comparing the accounts, and observing the different names given to God, is that we see clearly two writers must have been employed.

The story of the Flood is also the work of two hands. Compare Genesis vi., from verse 9 to end of the chapter, with the following chapter. The first part is by the Elohist, who says, take of "every creature, two of *every* sort"; but the second is by the Jehovist, who says of "every clean beast thou shalt take to thee by sevens," and "of beasts that are not clean, by two." The words "clean" and "unclean" point to a time later than that of Noah, and probably long after that of Moses, and when the law was well established.

The character of many of the early statements seem poetic rather than historic; such as the speaking Serpent, the familiar intercourse with God and angels, the immense gathering of wild beasts from all lands into Noah's limited ark in the short space of one week, the strange account of the origin of languages at an apparent date long after the establishment of the Egyptian monarchy, the marvellous miracles of Moses which impressed his generation so slightly, the powers of the Egyptian magicians, who could make frogs in vast numbers at once, the stopping of the sun and moon, the prolonged age of the Antediluvians, and the statement respecting giants. These wonderful things demand more evidence than has yet been adduced; but are in general harmony with the early stories of some other nations which we look on without particular respect.

The Assyrian or Babylonian origin of some of these stories is probably because—

1st. Babylonian civilisation long preceded the establishment of the Hebrew nation.

2nd. Because the Hebrew tradition is that their original ancestor came from the neighbourhood of Babylon, and we know that the Assyrians were Semites.

3rd. We find somewhat similar stories in Babylonia, on very early inscriptions. Indeed, Mr. Sayce and other good authorities consider that the stories of the Flood and Creation were current there at least 2,000 years B C.

The Number 7 seems to have been considered holy there, and was derived from observing that there are seven heavenly bodies which move visibly across the sky, namely, the Sun, Moon, Mercury, Venus, Mars, Jupiter, and Saturn. Of their temples Fergusson says in his "History of Architecture," that they were in seven stages, and of the "Birs Nimroud," says it was "dedicated to the seven planets."

Mr. Sayce says of ancient Babylonian time measures, "So also the week of seven days, which was closely connected with the early astronomical studies of the Accadians, the days of the week being dedicated to the moon, sun, and five planets. The 7th, 14th, 21st, and 28th days of the lunar month were kept like the Jewish sabbath, and were actually so named in Assyrian," the Assyrian *Sabathi* or "Sabbath," itself being further defined as meaning "completion of work" and "a day of rest for the soul."

Respecting the Deluge, Mr. Sayce gives many notices, such as "Among the latter is the Epic of Gisdubar in its present form, which is based upon an astronomical principle, the subject matter of each of its twelve books corresponding with the name of a Zodiacal sign. The lion is slain, for instance, under the Zodiacal Leo, the sign of Virgo answers to the wooing of the hero by Istar, and the sign of Aquarius to the episode of the Deluge."

As to the date of the Deluge "F.R.A.S." need not trouble much about a year more or less, seeing that all eminent writers place the date of Manetho, the first monarch of United Egypt, at least 1,000 years before the date usually ascribed to the Flood; while some, including Mariette, one of the best authorities, places Manetho 2,675 years before the Flood.

The oldest notices of Egypt, and the most ancient of its works compel us to believe that an immense time must have elapsed previously, to account for the strange peculiarity of everything concerning it. Indeed, as Mr. Sayce says, "as far as our present materials and knowledge are concerned, the Egyptians were as autochthonous and isolated as their own civilisation." **Memnon.**

[24008.]—I DO not wish to enter the lists of theological controversy; but I had rather your recent correspondent, "J. H.," had assumed some other initials than those with which I have hitherto subscribed myself, particularly as the sentiments he avows are utterly at variance with those which I have painfully and laboriously acquired. I look upon all attempts to harmonise the old Hebrew fables with scientific fact as utterly hopeless. To me, the early history of man is written, not in Genesis, but in the caves and the river drift; in the celts and the arrow heads—implements before the date of whose vast antiquity the 6,000 years of Usher are but as yesterday.

I would rather glory in the thought that we inherit and are indebted to the labours of myriads of toiling generations whose origin is lost in the dim vistas of utter barbarism, than accept the story of the Fall, with its consequences of everlasting degradation and awful torture for the majority of the race. **J. H.**

[24009.]—"MEMNON" (letter 23980) states that there are two sets of Commandments—one in Exodus xx., the other in Deut. v.—each containing explanations respecting the Fourth Commandment, and both *differing radically*. I answer, certainly the Ten Commandments are written in both the above books, and that the sense is the same in both places. The *reason* for keeping the Fourth Commandment is given in Exodus xx., as God resting on the seventh day from His work of creation, as in Gen. ii. 3. In Deuteronomy a special reason is added why the Israelites should keep this Commandment—viz., they had been slaves in the Land of Egypt: God had delivered them, and therefore they were to keep it.

In Exodus a reason is given why men should keep this Commandment. In Deut. a reason why more especially the Israelites should keep it.

"Memnon" states that the reasons why the Mosaic origin of the Pentateuch is doubted are:—

1. Because the language used in it is the very same as that used in books known to be later in date. Remembering the difference between the English of Chaucer and that of to-day, he fails to

see how Moses can have written in the style of David or Ezra.

The answer is, that in the Pentateuch there are archaic words and grammatical forms not used by any later writer. For instance, the Hebrew word *hoo* (he) is used for the feminine (she) in 195 places, the proper feminine occurring only in 11 places. The word *naar* (a boy) is used in 21 places for the feminine *naarah* (a girl). The pronoun, with the article prefixed, *hallazeh*, Gen. xxiv. 65, xxxvii. 19, in all books after the Pentateuch, is shortened into *hallaz*. For a great many more examples of differences in words and spelling, &c., see Keil's "Introduction to the Old Testament," chap. 2, sec. 15. "Memnon" states that as the Israelites numbered but 70 souls when they entered Egypt, they could hardly have a settled language of their own. I am not aware that it is necessary to think they had a language peculiar to themselves. They spoke the same language that was spoken by the inhabitants of Canaan—viz., Hebrew. This is evident from the names which Canaanitish towns and persons bore. Examples:

| | |
|---|---|
| Kirjath Sepher ........ | City of Books. |
| Kirjath Arba.......... | City of Arba. |
| Melchizedek .......... | The righteous King. |
| Zeeb .................. | The Wolf. |
| Oreb .................. | The Raven. |

It is stated further that Genesis is clearly made up of several books written by different people, and joined together by an editor, who clearly lived at a later date. The same editor, it is stated, mentions the death and burial of Moses in Deut. xxxiv. Now, as anciently there was no division into chapters and verses, I think it is quite obvious that the last chapter of Deut. (the xxxiv.), containing the above account, really belongs to the beginning of Joshua, and, if so, the editor alluded to wrote no part of the Pentateuch.

"Memnon" further states that the editor lived long after Moses, because, in Gen. xxxvi. 31, we read, "These are the kings that reigned in Edom before there reigned any king over the children of Israel." This is explained without having recourse to a later editor. In Gen. xvii. 6, God there promises to Abraham that "I will make thee exceeding fruitful, and I will make nations of thee, and kings shall come out of thee." And, again, to Jacob, "A nation and a company of nations shall come of thee, and kings shall come out of thy loins." Moses, therefore, merely noted that Edom had kings before Israel had any, although they had been promised to both Abraham and Jacob. There is, therefore, here no proof that the verse in dispute was not written by Moses.

March 21. A. O.

## THE STATE OF MAN.

[24010.]—I would call the attention of "O. J. L." to the following list of works, as containing about the best that can be said on the subject of primeval man, from different points of view:—"Reliquiæ Diluvianiæ," by Rev. W. Buckland, 1823; "Cave Hunting," by W. Boyd Dawkins, 1874; "Etudes sur l'Antiquité Historique," par F. Chavas, 1873; "The World before the Deluge," by L. Figuier, 1867; and "Primitive Man," ditto, 1876. At the same time "O. J. L." will find, like most others, he will have to form his own conclusions, as the points of view and the periods of time are so different and diverse, as an instance or two will show. The idea of a Deluge such as told in Genesis has been ridiculed and scouted as an impossibility, from the supposed want of water; and yet we are gravely informed by these theorists that America was covered by glaciers from 7,000ft. to 8,000ft. in depth, and all Europe bears evidence of having been also covered by such another cap of solid ice. Again, the whole theory of Palæolithic man is founded upon chipped flints found in the gravels—such as at the bottom of the peat and silt formations of the Somme Valley, &c., making out man to have been upon the earth more than 300,000 years. And yet you may get a cartload of those same chipped flints in any of the chalk-pits of Hertfordshire, some of which have only been opened within a few years back. All the real flint implements used by man are Neolithic, and have always been found along with bone needles, &c., as in the remains of the Swiss Lake dwellings, along with traces of bronze, crucibles with a small bead of copper in one of them, quantities of corn, baked cakes of bread, flax, glass beads, perforated stone axes, and the remains of the dog, pig, sheep, and cow. The calculation of M. Marlet, accepted by Sir John Lubbock, mentions 6,400 years as the time that has elapsed; and Prof. Wursaal, in his "Primeval Antiquities of Denmark," thinks it was some 3,000 years ago; very different from the 200,000 years of others. But after all said and done, "O. J. L." cannot go very far wrong if, as "J. H." (23927) says, "put God at the helm of affairs," and abide by the statement of the old Record, that that same God made man upright and in his own image; but that man hath sought out many inventions, one of which was the breaking of the order of His being; and so, while some of the nations kept up the line of civilisation, which has never been lost, others have fallen away; but as you cannot get out of anything what is not in it, so man, had he been introduced as a primitive savage, would have remained so; but as far back as we can get in history and tradition, there have always been races of men who were quite able to hold their own with any at the present day.

Dens.

[24011.]—This subject is now ramifying, as I feared would be the case, and it is difficult to say to what dimensions it would attain were it not in the Editor's power to make use at any moment of the clôture.

I think it is pretty evident that much must rest on conjecture, unless we are prepared to accept the Mosaic account as beyond controversy a direct revelation; and I do not think such a theory tenable, nor do I know that Moses ever claims it as such. The Egyptian monument referred to, in which, in a series of pictures, the Six Days' Work of Creation is delineated may have been the work of the Israelites themselves, in order to prevent their own tradition dying out; or it may have been Egyptian work executed with the same object. It *proves* nothing.

To my own mind it is as difficult to accept the theory of development from a mythical protoplasm as to accept the Mosaic theory—even if God be placed at the helm in either case. Internal testimony is, I think, strongly in favour of a later date to the Pentateuch than the time of Moses, and I have long regarded the story of the Fall as allegorical; nor can I believe that the various types of humanity sprang from that one erring pair. It was suggested, however, to me lately by a lady, that the mark set upon Cain was the darkened skin and negro type of countenance, man having been created fair, and that thus originated the beauties of Africa. But then comes the difficulty of the Flood, which the thus blackened race apparently did not survive. Having asked for information upon a certain point, I have to thank all who have endeavoured to enlighten me, many of their letters being of great interest; but I think I can perceive that proof is unattainable, and that the mystery of Genesis must remain a mystery still. I certainly do not look to theologians to solve the riddle; but believe that science may do so, only the time is not yet. O. J. L.

[24012.]—In connection with the interesting correspondence now going on in your columns as to the "origin of man," &c., will you allow me to suggest to fellow-readers that the apparent discrepancy between the Biblical account of the Creation, and the views thereof deduced by geologists, arises from an under-estimation by the latter of the "power" at work. Thus the duration of the later Glacial epoch is estimated at 250,000 years. But it is evident that 91,250,000 times the power required to do the work in that period would effect the same results in one day, and as *omnipotence* was engaged in the Creation, this amount of power, together with all allowances for friction and other loss, could have been, and was, available.

I would also suggest that the Biblical account does not say that Adam was the only man created, and that the narrative ceases to be general about Genesis ii. 6, and becomes a particular history of one race; just as in Chap. xii. of the same book it becomes the history of one family.

It seems only reasonable to suppose that possibly in the early part of the history when such enormous forces were engaged, that, for some time after the actual Creation, the earth's various revolutions were far more rapid than at present, and, therefore, the years shorter, thus accounting for the long lives stated. Would one or other of your astronomical readers kindly tell me, after due consideration, if there are reasons for or against this supposition; and, if so, what they are? and thereby greatly oblige and interest T. F. W.

[24013.]—"O. J. L." seems to be in a difficulty in regard to the Bible chronology by his taking it for fact, instead of speculation, that "human existence antedates" the Glacial period. Now, there is no more *vexed question* with geologists than this Glacial period, and opinions differ as wide as the poles asunder; but up to the present time there has been no real evidence that would stand a moment's investigation in a court of justice to show that man has been on the earth for more than 6,000 or 7,000 years, and if "O. J. L." would read up the observations of the American geologists, he would soon see they have little or no faith in the deductions of their English brethren in regard to the great antiquity of man. Principal Dawson, of Montreal, in "Sketches of the Geological Periods," says: "In like manner I fail to perceive, and I think all American geologists acquainted with the pre-historic monuments of the Western Continent must agree with me, in the want of any evidence of great antiquity in the caves of Belgium and England, the kitchen middens of Denmark, the rock shelters of France, and the lake habitations of Switzerland. I may merely add that the careful and elaborate observations of Dr. Andrews on the raised beaches of Lake Michigan, observations of a much more precise character than any which, so far as I know, have been made of such deposits in Europe, enable him to calculate the time which has elapsed since North America rose out of the waters of the Glacial period, as between 5,000 and 7,000 years. This fixes at least the possible duration of the human period in North America, though I believe there are other lines of guidance which would reduce the residence of man in America to a much shorter period."

Very different from the "quarter of a million years" "O. J. L." mentions. As for palæolithic man and his flint flakes, he is only a myth, based upon just the same theoretical ideas as evolves man from Miocene apes scourged into humanity by the horrors of the glacial period. Very good as deductions to those that like them; but the accounts given in the fragments of old records preserved in Genesis have not as yet been upset, but rather the contrary; the pendulum is slowly but surely swinging back in that direction, and as the records of the Deluge have been found and placed in the British Museum, it is just possible we may yet get some of the Antediluvian records from the same source. And, in conclusion, I would ask "O. J. L.," did it ever strike him as very curious, what a very small population, both of man and animals, there is upon the earth, if they have been upon it for 250,000 years or more, and what a miserably small amount of remains have been found for such a long period in which to have lived and multiplied?

March 23rd. Dens.

[24014.]—It is refreshing, after the positive manner in which some of our friends write of the Glacial period as though the whole world was at one time covered with ice, to turn to the calm and sensible letter of "A Fellow of the Geological Society," who informs us, as I think, very clearly that no such age ever existed; that the Glacial period is local, and as much to-day that epoch as it has ever been; and that each surface of the earth may in turn have had its own glacial age, whilst other portions at the same time had sunshine, heat, and fertility. If "J. H.," "O. J. L.," and others who think differently will take a small section—the east coast of our own little England, for instance—they will find everywhere traces of mighty rivers, high banks clearly carved out by long ages of water, sometimes even a mile wide, where now flows only a little brook not worthy to be called a river. A big river means the draining of a vast continent; such a continent must have existed, and has sunk countless ages ago below the ocean level, leaving only Great Britain and these records of its existence. Now, supposing the same depression is silently taking place in Switzerland, too slowly for man to even suspect the fact, in some distant epoch the ranges of the Alpine peaks will be what England now is, undulating and fertile, but with everywhere a trace of the great glacial period of their existence. The alteration of the levels of the earth's crust, always proceeding silently and almost unobserved, would thus account in a large degree for the marine fossils on the tops of lofty mountains, and the glacial scratchings on hard rocks in low-lying lands. But there is another age of which none of our correspondents on this interesting topic have touched—the drift, and the countless ages that preceded it. If "J. H." will get a map of the world on Mercator's projection, and rule a nearly straight line down from the Arctic Ocean a little to the west of the American lakes, on to the Antarctic Ocean, and another straight line to the east of the Volga again to the extreme south, he will have practically taken in about half the globe. Between these lines everywhere, in varying thickness, is found that marvellous mass of unstratified clay and gravel which we term the drift, filling up valleys, carved through by rivers, but lying upon the surface of the earth, or only buried by volcanic ashes or drifting African sands. At what distant time, or from whence came this mass of matter, is a mighty mystery, but there it is; and yet below that drift, sometimes at great depth, is found, by evidence which cannot be gainsaid, the remains of the works of prehistoric man. In the words of Tennyson—

> "There rolls the deep where grew the tree.
> O earth, what changes hast thou seen!
> There, where the long street roars, hath been
> The stillness of the central sea.
>
> The hills are shadows, and they flow
> From form to form, and nothing stands;
> They melt like mist, the solid lands,
> Like clouds they shape themselves and go."

Priam.

[24015.]—With reference to the interesting correspondence now appearing in your valuable journal under this head, I beg to inclose an extract from the "Diary of a Tour through Oudh," by my grandfather, the late Sir W. H. Sleeman, then the President at Lucknow, which seems to me pertinent to the matter. If desired, I can send other accredited instances of children brought up by female wolves from the same book:—

"There is now at Sultanpoor a boy who was found alive in a wolf's den, near Chandour, about ten miles from Sultanpoor, about two years and a half ago (1848). A trooper, sent by the native Governor of the district to Chandour to demand payment of some revenue, was passing along the bank of the river, near Chandour, about noon, when he saw a large female wolf leave her den followed by three whelps and a little boy. The boy went on all fours, and seemed to be on the best possible terms with the old dam and the three whelps, and the mother seemed to guard all four with equal care. They all went down to the river, and drank without perceiving the trooper, who sat upon his horse watching them. As soon as they were about to turn back, the trooper pushed on to cut off and secure the boy; but he ran as fast as the whelps could, and kept up with the old one. The ground was uneven, and the trooper's horse could not overtake them. They all entered the den, and the trooper assembled some men with pickaxes, and dug into the den. When they had dug in about 6 or 8ft., the old wolf bolted with her three whelps and the boy. The trooper mounted and pursued, and headed them, and turned the whelps and the boy back upon the men on foot, who secured the boy, and let the dam and her three cubs go on their way.

"They took the boy to the village, but had to tie him, for he was very restive, and struggled hard to rush into every hole or den they came near. They tried to make him speak, but could get nothing from him except an angry growl or snarl. He was kept for several days at the village, and a large crowd assembled every day to see him. When a grown-up person came near him he would try to steal away, but when a child came near him he rushed at it with a fierce snarl like that of a dog, and tried to bite it. When any cooked meat was put before him, he rejected it in disgust, but when any raw meat was offered, he seized it with avidity, put it on the ground under his paws like a dog, and ate it with evident pleasure. He would not let anyone come near him while he was eating, but he made no objection to a dog coming and sharing his food with him. The trooper remained with him four or five days, and then returned to the Governor, leaving the boy in charge of the Rajah of Hasunpoor. He related all that he had seen, and the boy was soon after sent to the European officer then commanding, Captain Nicholetts, by order of the Rajah of Hasunpoor, who was at Chandour, and saw the boy when the trooper first brought him to the village. This account is taken from the Rajah's own report of what had taken place.

"Captain Nicholetts made him over to his servants, who take great care of him, but can never get him to speak a word. He is very inoffensive, except when teased (Captain Nicholetts says), and will then growl surlily at the person who teases him. He has come to eat anything that is thrown to him, but always prefers raw flesh, which he devours most greedily. He will drink a whole pitcher of butter milk when put before him without seeming to draw breath. He can never be induced to wear any kind of clothing, even in the coldest weather. A quilt stuffed with cotton was given him when it became very cold; but he tore it to pieces, and ate a portion of it with his bread every day. He is fond of bones—especially uncooked ones—which he masticates apparently with as much ease as meat. He has eaten half a lamb at a time without any apparent effort, and is very fond of taking up earth and small stones and eating them. His features are coarse, and he is very filthy in his habits. He continues to be fond of dogs and jackals, and all other four-footed animals that come near him, and allows them to feed with him if he happens to be eating when they approach."

**Hugh Lockhart Ross.**

## ETERNITY OF MATTER.

[24016.]—To get back to the time when all was infinitely hot, we must go back through an infinite time, for however far we go, we can always imagine an anterior and hotter time.

**E. G. Tindall.**

[24017.]—In reply to "A. W." (23997) I would point out that although the material universe at present exists in a state of heat, it did not necessarily always exist in that state, as heat is merely a *state* of matter which may be imparted to such through its coming within certain forces (either chemical or otherwise).

Therefore, although the universe—so far as we are able to see it—may at present exist in a state of heat, its elements, after having parted with that heat, may again be brought within such influence as will cause it once more to assume a state of heat equal to that which previously existed within it.

It is, of course, impossible to say what the origin of this heat is; but it is probable that it is brought about by the continual motion which matter as a whole assumes through space.

**R. W. B.**

## EXPERIMENTS ON FRICTION.

[24018.]—Those who are interested on the subject of friction set up in the bearings of screw shafts of steam vessels I submit should pay a visit to South Kensington Museum, and study the patent screw shield of the late celebrated Robert Griffiths ("Screw Griffiths"), or to Mr. A. A. Wade, M.A., F.R.S.A., 108, Fleet-street, who has a rough model, and will be glad to show it; and also see the discussion on Barnaby's hydraulics, which took place last year at the Institution of Civil Engineers, Great George-street. The shield has the effect of giving an equal grip to the propeller throughout the entire revolution, thereby preventing the great pressure on the upper bearing, does away with vibration, and gives from six to eight better results. Mr. Wade will give particulars to inquirers.

**C. Curtis, Retired Captain, R.N.**

## A TWO-INCH SPARK COIL.

[24019.]—Your printer has, I see, in setting up my description of this coil, termed it a "Quick spark," instead of a "2in. spark" (as I wrote it), which may much exercise the minds of some of "ours" to know what it means, unless corrected.

**B. Harcourt.**

## MUSICAL SCALE.

[24020.]—On page 10 of "our" new volume Mr. S. E. Hunt gives an exposition of the ratios of the notes of the natural scale according to the harmonic theory. I call it the harmonic theory, because, according to it, the points at which a monochord sounding the keynote must be stopped or shortened to produce the other notes of the scale are some of its nodal points—points which remain unmoved when the string, becoming divided into a number of equal parts, vibrates in each of these parts separately, and gives forth a "harmonic" note, the pitch of which corresponds to the length (and, of course, number) of the subdivisions. These harmonic notes can easily be produced on a monochord by gently touching it at a nodal point while it is being struck or plucked, or otherwise caused to vibrate. Thus, if the middle point is so touched, the two halves of the string vibrate separately, giving the harmonic note due to the half-length, which note is the octave above that sounded by the whole string. When the string is stopped at the same point—that is, if its effective length be reduced one half—the resulting note is the same. If it is touched at either of the nodal points which divide it into three equal parts, the harmonic note produced is the octave above the fifth of the scale of which the whole string sounds the keynote. When the string length is reduced to two-thirds by stopping it at the same point, the fifth note of the scale is sounded. If touched at one of the nodal points which cut off a quarter of the length from either end, the string sounds the harmonic note, which is two octaves above the keynote. Reducing its length to three-quarters by stopping it at the same point makes it sound the fourth of the scale. These simple harmonic ratios having been found to subsist between the keynote and the octave, the fifth, and the fourth of the scale, it seems to have been assumed that similar ratios must also exist in the case of all the other notes of the scale. Mr. Hunt, indeed, goes so far as to say that "the natural musical scales appear to arise out of the *demand* of musical ears" for such ratios. Now, all that musical ears demand is only that the notes of the scale shall sound *in tune*. They no more take note of ratios, simple or other, than does the eye of the different rates of light-vibration which impress it with a sense of various colours. Assuming, then, that the second, third, sixth, and seventh notes of the scale *must* each bear some simple ratio to the keynote and other notes, Mr. Hunt assigns to them certain values which he gives in a table, showing ratios ranging from $\frac{4}{5}$ (which is simple enough) for the major third, to $\frac{8}{15}$ for the major seventh, $\frac{9}{16}$ for what he calls the "grave minor seventh," and $\frac{15}{16}$ for "flat minor second"; none of which latter can be called very simple. He has two major seconds and two flat sevenths—apparently because he could not find a single second or flat seventh which would answer the requirement of bearing simple ratios at once with the keynote and with other notes of the scale. One of these duplicated notes is, it seems, used only in ascending passages, and the other in descending ones; because "the ear prefers the large tone to the small one when the choice is offered." Now, this "large tone" is the correct $\frac{8}{9}$ interval, the small one the disputed $\frac{9}{10}$ interval. If, as Mr. Hunt truly says, the ear prefers the former, surely that fact should cast considerable doubt upon the correctness of the latter. Does the ear demand simple ratios, and yet prefer an interval incompatible with them? I find (*by experiment*) not only that the ear prefers this "large tone" for all the whole-tone intervals of the scale, but also that the reduction of two of them to $\frac{9}{10}$ necessitates a widening of the semitone intervals, which is most unsatisfactory to the ear. In fact, I believe it is only a defective musical ear which can accept as in tune a scale in which any other ratios than $\frac{2}{3}$ for all the fifths and $\frac{3}{4}$ for the fourths are admitted. A series of notes calculated upon the basis of these two ratios (see monochord scale, page 478 of the last volume) embraces a complete and consistent system of diatonic scale in every possible musical key, each key being related to certain others according to the laws of musical modulation. Every note in it has a definite and invariable pitch in relation to the others, which does not require to be altered in changing from one key to another, or from ascending to descending phrases. It is the want of this consistency and fixity in the harmonic scale which seems to have puzzled Mr. Cass and, no doubt, others. Taking that scale as perfect, "J. A. S." was quite correct when he supposed that the key of G must require *two* notes not to be found in the key of C; not only a new seventh (F sharp), but also a new second which will change the first interval from $\frac{9}{10}$ to $\frac{8}{9}$ of the keynote. This, however, as every musician knows, is not necessary, and the reason is that the interval G-A is the same ($\frac{8}{9}$) in both keys. The inconsistency of the harmonic scale may be shown thus: Calling the keynote C 1, we have D ($\frac{8}{9}$) = 0·888, E ($\frac{4}{5}$) = 0·8, G ($\frac{2}{3}$) = 0·666, A ($\frac{3}{5}$) = 0·6. Here E, being made $\frac{4}{5}$ of the keynote C, is necessarily $\frac{9}{10}$ of D. But E is also the second of the key of D, and in that capacity it must be $\frac{8}{9}$ of D, or 0·7911. Again, A, besides being the sixth of the key of C (as which it is said to be $\frac{3}{5}$ of the keynote, and $\frac{9}{10}$ of G) is likewise the second of the key of G, and the fifth of the key of D; but in either of these cases its value is not 0·6, but 0·592. Thus the harmonic theory unavoidably gives two separate values to each of two notes of the scale (to begin with). Each of these four values of course forms a starting-point or keynote from which to calculate other values, and there are thus produced four different sets or systems of notes. But every new third and sixth of a scale so calculated necessarily assumes two separate values, as did those of the original scale. These in their turn became fresh starting-points or keynotes for new sets of scales, and consequently there results, if the process of calculation is carried far enough, an innumerable host of values assignable to every note of the chromatic scale. In the the true natural scale, I repeat, every note has, and can have, only a single value which bears a definite ratio to that of every other note, according to its distance in the scale from it, the same distance in every case giving the same ratio.

On page 37 in "E. M.," March 13, Mr. Elphick, in reply to me, undertakes to try to prove the correctness of the harmonic scale. His offered proof (of "the mathematical part of it"), which at first sight looks alarmingly elaborate, turns out to be nothing more than showing that the ratio of each note to the keynote agrees with the product of all the intermediate interval-fractions multiplied together. Mr. Elphick does not seem to be aware that this is a mere illustration of a general arithmetical fact which is true of any series of numbers. Thus, suppose we take the arbitrary series $\overset{a}{10}\ \overset{b}{7}\ \overset{c}{4}\ \overset{d}{3}$, the successive fractions representing their ratios are $\frac{7}{10}$, $\frac{4}{7}$, $\frac{3}{4}$. Now, $a = 10$, $b = \frac{7}{10}$ of $a$, $c = \frac{7}{10} \times \frac{4}{7} = \frac{28}{70} = \frac{4}{10}$ of $a$, and $d = \frac{4}{10} \times \frac{3}{4} = \frac{12}{40} = \frac{3}{10}$ of $a$; but it is evident that $d$ would still have been $\frac{3}{10}$ of $a$, whatever other numbers had been chosen for $b$ and $c$. In the same way, in the scale the ratio of any note to the keynote will remain unchanged, whatever values may be given to the intermediate notes, and if Mr. Elphick will apply his method of proof to the monochord proportions and intervals given on the same page with and immediately preceding his reply, he will find them also correct; but of course the process is no proof at all. Having given his supposed proof, Mr. Elphick proceeds to show the anomalous nature of the harmonic scale by pointing out that every interval in it except the octave has no less than three different dimensions according to the part of the scale in which it occurs, and he makes this confusion worse confounded by reckoning the *minor thirds* among the "thirds"; also by classing the interval F—B as one of the fourths, the true fourth interval above F reaching to B flat. Moreover, he points out particularly that two of the so-called fifths fail in the sum of their component intervals to make up the $\frac{2}{3}$ ratio necessary to constitute a real fifth. One of these two however (B to F), is not, at any rate, a fifth at all, the real fifth above B being not F, but F sharp. I offer Mr. Elphick my best thanks for so ably assisting me in demonstrating the inconsistencies of the harmonic scale. In concluding, Mr. Elphick assures us that he has tested theory by the aid of certain wind instruments; but it is questionable whether these were instruments of precision capable of making the exact measurements required in a scientific investigation. I would advise him rather to use an accurately-divided monochord, and try its effect upon persons having reliable "musical ears." **Walter Bardie.**

9, Dalkeith-street, Joppa, March 16.

### PNEUMATIC TRANSMISSION OF THE MAILS BETWEEN LONDON AND PARIS.

[24021.]—In the Scientific News of the "E.M.," March 20th, it is stated that a plan has been devised by a M. Berlin by which mail bags can be sent 295 miles in one hour, with an engine power of from 20 to 30 horses. I, and probably all your readers, would be glad to have further information on what would appear to be an enormous advance over methods now in use.

A paper was read at the Institute of Civil Engineers in 1872, which led to a very interesting discussion, in the course of which Mr. E. A. Cowper, no mean authority, spoke to this effect:

If it were attempted to carry heavy mails at high speed through tubes, friction must be reduced by increasing the size of the tube. A pipe 24in. diam., 4 miles long, would only give a speed of 47 miles an hour, with a vacuum of 11lb. per square inch. With proper arrangements for letting in the air every half-mile, a speed of 131 miles an hour might be maintained if the piston would bear the wear and tear. The power required, however, would be about 390h.p. every 4 miles.

The pneumatic system in London requires three 75 h.p. (indicated) engines for very light carriers, and a speed under 20 miles an hour. This being so, one cannot well help feeling a desire to know more of a system said to be able to carry heavy weights 295 miles in a single hour, with 30 h.p. engines, even if one is mistaken in supposing that the paragraph intends to convey the idea that only one such engine is required.

It may be said that a speed of sixty miles an hour was obtained on Brunel's atmospheric railway; but there the air was admitted directly behind the piston, so as to avoid the necessity of moving a long column of air, the friction of which constitutes one great difficulty of the problem.

**Emeritus.**

### DR. KOCH'S "COMMA" BACILLUS.

[24022.]—Might I ask you to allow me to point out a slight mistake in your report of the proceedings of the R.M.S. in your issue of March 20? The drawing I exhibited was of Dr. Koch's "Comma" bacillus, and not of the *B. subtilis* as stated.

Before Mr. Fowke's statement can be accepted "that the Comma bacillus of cholera was known and recognised 35 years ago by Messrs. Brittain and Swayne," two points want to be proved: 1, That the art of staining micro-organisms was known at that date; 2, that the "microscopy" of that day was equal to the occasion.

In the term "microscopy" I include the whole of the brasseries, glasseries, lighteries, and *the method of using them*, so as to develop their full powers.

I believe I am correct when I say that an unstained "comma" bacillus has never been seen by the "microscopy" of the highest type of the present day; also that the art of staining micro-organisms is a comparatively recent invention.

It is very unlikely that Messrs. B. and S. possessed "microscopy" so far in advance of that which we believe was extant at the period stated as to be enabled to discover the "comma" bacillus.

March 21. **Edward M. Nelson.**

### MINERAL-OIL LAMPS.

[24023.]—I have read with some surprise the extract in this week's "E.M." of Sir F. Abel's lecture on "Mineral-Oil Lamps" in respect to metal containers, and as his observations are so much at variance with practical experience, I think a little more explicit information from him (the highest authority on the subject) would be of general interest, as while these lamps are made in their present form any general adoption of his views might, in ignorant hands, lead to disaster.

Sir F. Abel distinctly advocates the use of metal containers in preference to opal glass or earthenware. Now, these latter materials have been adopted by all the best makers, as, from the fact that they are non-conductors of heat, they are the best substances to use, and consequently the only safe containers for lamps of the present make; for metal heats at once, and in a very short time raises the oil to a temperature that throws off inflammable vapour, and, in fact, converts the ordinary domestic lamps into a "close testing machine, without the safeguards possessed by that article."

The "flashing point" of average oils in the close test is but little above 75°, and in an open test is from 107° to 115°, and as any metal container, with an ordinary wick at full combustion, will soon raise the temperature of the oil above the highest of these, and though there may be no opening near the flame, yet if the wick should be in the least too small for the sheath, the vapour must mount beside it and directly enter the flame. This will not of itself of necessity cause an explosion, as if the stream of gas so escaping be limited, it will be steadily consumed by the flame to which it is carried by the upward draught of the chimney; but let this draught be checked, by carrying the lamp about, or blowing down, or even across the top of the chimney, an explosion is very likely to happen.

Sir F. Abel advocates the filling of the container with oil; this he does for stated scientific reasons—let me add a practical one: Few wicks have a "pull" beyond 4in. from the point of ignition, and that only with the better class of oil, consequently, the fuller the container is, the shorter is the "pull," and the better the light from the more perfect combustion of the oil.

What, I have no doubt, the learned Professor meant was that "as lamps are now made," it was better to choose the lesser of two evils, for the opal or glass container lamps so easily break on being let fall, and the concussion converts the oil into a spray, mixed with atmospheric air, which is the most dangerous condition possible. But I am convinced that far more danger would accrue from the general heating of the oil in metal containers than from the few occasional fractures. **J. Hughes.**

### GRATES.

[24024.]—In the "E.M.," No. 1032, January 2, your correspondent "Dover" makes a suggestion about an addition to our "common English grate," and asks for any practical correspondent to criticise his idea. Without presuming to do this further than saying I do not consider the presence of water quite in character with a drawing-room or sitting-room, I will state what I did to my drawing-room in a house where the fireplace was against the outside wall, with a similar intention of utilising the heat.

An opening was made from the outside exactly opposite the centre of the grate, to lead into a channel made at the back of the grate level with the hearth, which channel divided behind the ash-place, and passed up both sides behind the sides of the register stove, uniting again into one large channel made at the back of the mantelpiece, and an opening 1in. wide was made into this cross channel the whole length of the mantelpiece, opening underneath the looking-glass, the looking-glass being raised 1in. to allow the warmed air to enter the room through this opening.

By this arrangement all persons at or near the fire experienced a pleasing and most refreshing current of warmed fresh air, which passed afterwards into the room and, rising, mixed with the results of combustion from the gas, uniting with the cooler air on the opposite side of the room and returned with a lower current to the fireplace, thoroughly ventilating the entire room. The course it took from the mantelpiece had often been followed and traced by the aid of placing anything giving off smoke on the mantelshelf and observing the direction it took; this was invariably as described, and the agreeable character of the air in the room and the success of the principle received the approval of all who remained in the room for any length of time. The opening in the outside wall was covered by a perforated door, and inside the door was fixed a sheet of canvas or wool, or of any other fibrous material, to filter the air; this was found necessary from the large quantities of impurities always present in the air of London. This diaphragm was replaced by a fresh one as often as found necessary by the air not passing in freely. Should any of our readers care to try this experiment, they would be very pleased with the result. **J. S. B.**

### LATHE MATTERS.

[24025.]—The question of the possibility of hardening lathe mandrels with the least degree of warping, or without distortion, must rest in the hands of those who, by the selection of the most suitable metal, manipulated with this object solely in view, and who are willing to experiment in this direction. I have given my experience, which, of course, I expect to be negatived by those who will never deviate from the old groove; yet I can show good results.

If I had a prize to award for one of a series of mandrels by unknown makers, it would probably not fall to the share of the one most highly finished and dressed up; but for that with all the accuracy of the soft state retained, and having been untouched after hardening. It is not a difficult feat to turn up and finish a mandrel in the soft state; most average light turners can do this perfectly, and consider it nothing to brag about. I cannot reason with Mr. Hines, as he says that he uses "the very finest and best quality of cast steel" for his mandrels—a material that I repudiate for this purpose, because the finer and harder the quality of cast steel, the more certain it is to warp in the hardening.

I advocate the very mildest homogeneous steel, that without a little extra surface carbonising will not harden sufficiently to resist a file scratch.

I do not "evade the question" of makers who use diamond turning tools; but answer it in the way that I think most proper to those whom it may concern; and I shall be willing to notice further applications.

In a discussion of this sort, makers of foot lathes of course avail themselves of the opportunity of drawing attention to their own merits, or induce others to do so for them. Would Mr. Hines like me to announce another maker's lathes as preferable to his own for quality of workmanship? I think not; so those who ask my opinion must do so privately. But I may properly go beyond lathe makers. Sir J. Herschel turned up the hardened steel axes of his transit by means of a diamond. Mr. E. Troughton, F.R.S., also used a diamond turning tool for finishing up the hardened steel work in the instruments that he manufactured; so also that eminent maker of astronomical and philosophical instruments, Repsoldt, of Hamburg, and Julius Wanschaff, of Berlin, now exclusively use diamond turning tools for giving the high degree of accuracy to the hard steel spindles, &c., in the work for which they have acquired such celebrity.

With the aid of our best modern screwing lathes, screws and taps may be cut so as to run absolutely true in every part in the soft state. It is in the hardening operation that the distortion occurs, and the effort should be to quench them so as to remain free from error, so that the screw retains its perfection as a centring agent. Mr. Hines, however, names another liability to error—that "the first bruise on the end of the mandrel would spoil it." From this we may infer that the ends of his mandrel noses are soft. The knowing ones who before choosing a lathe feel the mandrel all over with the corner of a file may perhaps note this. He also informs us that the "model mandrel" as exhibited at the "soirée" should have the screw made as a "loose fit in the chucks," to allow them to accommodate themselves to the blank cylindrical base, and so in case of eccentricity the screw would not force the chuck against the mandrel face in the direction of its centre, but all on one side—a most complaisant state of uncertainty, to be sure. If the screw is turned absolutely true, and this truth can be retained in the hardening, then the cylindrical base is worse than useless, and we had better be without it. If, on the other hand, it is (as some would consider) impracticable to get a perfect screw hardened so as to remain true, then in cases where we can we had better dispense with it altogether for a mandrel nose, and make it as a slightly tapered plug, as this, of course, can be finished absolutely true after being hardened. Some of the mandrels for watchmaker's lathes are made this way, and Mr. S. Varley's optical lathe made sixty years back had a mandrel of this description. The lathe is described in Vols. I. and II. of "Gill's Technological Repository," from which I quote. "The mandrel of this lathe has a tapering end to it on which the chucks are fitted tight, by merely giving them a slight twist on placing them thereon. The proper degree of taper should be 4°; if of a greater angle than that, the work is apt to loosen the chuck, and it will come off the mandrel; and if of a lesser angle, it is liable either to burst the socket of the chuck, or to stick so firmly upon the mandrel as to endanger the work in geting it off." Of course this cannot be recommended for foot-lathes for heavy turning for which the chucks must be locked in some way; but I can show my friends a heavy engineer's lathe of recent construction meant for very accurate work, with a plain mandrel nose of this description, having a diameter of about 4in. The chucks are locked and drawn on the conical nose by a key passing through the sockets and through a slot in the mandrel end. This would not do for a lathe where the removal of chucks is frequent; but in a heavy engineer's lathe the work is nearly all done from the large face-chuck which is seldom taken off, even for turning between centres. I do not know whether this mandrel-nose has been turned up true after being hardened by a diamond turning tool. I think it probable. I should do it that way myself, but I can easily learn this from the maker.

In quoting "Vulcan" as having pronounced me altogether wrong in saying that a rotary cutter will produce a distorted thread, Mr. Hines has strayed beyond the lines. If he will refer to No. 23973, on p. 60 of this journal (last issue), he will see that "Vulcan" quite realises the position, and explains it graphically, having candidly withdrawn his first impression. Let a milling cutter or saw be set with its plane to line with the angle of the top of, say, a square-threaded screw. For the bottom near the axis, another angle of plane would be required with a greater twist; a clumsy compromise might be effected by turning away the sides of the milling-cutter and making it narrower at the edge so as to fit in the thread, and then finally to obtain an accurate square bottom, the periphery of the cutter would require to be hollowed out to an elliptical curve, and a most horrible job all this would be. I

have had something to do with screw-cutting where the greatest accuracy has been the aim, and the idea of having to work up and finish a fine-threaded and deep-cut screw for micrometrical or dividing purposes, by means of revolving cutters and grinders, is enough to make one shudder. If Mr. Hines, for the sake of maintaining his point, is trying to persuade us that for "standard taps," &c., the revolving grinder has been adopted, all that I could say further on this point might be summarised in the somewhat uncourteous phrase, I do not believe it, and this must be the end of the argument. I had given Mr. Hines a timely caution not to risk his status by being beguiled into supporting this gross error, originating from another quarter, which would necessarily bring replies to prove it as such. **F. H. Wenham.**

---

[24026.]—DOES Mr. Wenham really mean the diamond gem or bort or carbonado? I fancy the latter.

I like Mr. Wenham's expression, "the traversing mandrels trued up"—*i.e.*, not lapped or abraded, but turned up true by what he calls the diamond tool. There is no difficulty in setting pieces of a real diamond or pieces of carbonado in a tool. I fancy Sir Henry Bessemer has been using diamonds for cutting telescope lenses.

Mr. Wenham refers to case-hardening iron. I prefer the plan of which a practical manager of a large London manufactory told me—viz., take a piece of iron, put it into an iron tray or box filled with two-fifths of quarry limestone (black marble best) and three-fifths wood (oak) charcoal, cover up and put in a lid, put into a furnace and heat well. According to time of heating so will be depth of steel. I have done this, and in filing end I have seen the depth of steel, or steely or carbonised iron.

14th March. **Z. Y. X.**

---

## LATHE MANDRELS, CHUCKS, &c.

[24027.]—ON p. 562 Dr. Edmunds says: "If an acute cone were used we should need a very long (mandrel) nose, or we must go back to double surfaces." Fig 1, which illustrates my system, No. 1, is a section of a double steel mandrel nose, and it will be seen that, for the sake of comparison, I have adhered to as many of the dimensions of the Standard mandrel as possible, and in order to increase the length of the cone, which is one of an angle of 20°, I have made the hard steel collar project slightly, the base of the cone being countersunk to receive it. I do not know that I should recommend this in practice, as it might tend to weaken the mandrel neck; but whilst securing a length of cone of $1\frac{19}{32}$in., it still necessitates the nose projecting only 1¼in. beyond the support of the collar, or, in other words, a length of projection identical with that of Dr. E.'s design, and I presume that a cone of such length will not be called a very long one; and, being tapered to an angle of only 20°, brings it within the definition of an acute cone, so we are not yet "obliged to come back to the two (*rectangular*) surfaces." In Fig. 2, which is an end view of the nose, and in Fig. 3, which is an elevation, the triple bayonet joint, the means employed for keeping the chuck in its place, is clearly shown, the spiral part of which is about 1in. pitch. This, in all probability, would be much improved by being made of much greater pitch, the precise amount being governed by the angle of conicity given to the nose. The chucks coned out to accurately fit this mandrel would have three equidistant holes bored in the same plane, into which the hard steel pins (Fig. 4) would fit tight, the flat surfaces of which would engage with the sides of the bayonet joints. Fig. 5 is a view of the rectangular surfaces of the Edmunds mandrel, and if we take A as the centre about which angular variation or declination takes place, we should find that the opposing surfaces to motion in an upward direction are represented by the lines A B and *a c*, and to motion in a downward direction by surface A D only; see Fig. 13 for comparison of length of these resisting surfaces with those afforded by my (Fig. 1, 2, 3) mandrel nose; and now turning to Fig. 6 and taking corner A as a centre of angular variation, we find that the side P *c′* would oppose such upward motion, as shown by arcs H G, F E, and D *c′*, which are intercepted by the suface P *c′*, the distance from A to P being 2in. and from A to *c′* $2\frac{19}{32}$in., or more than ⅝in. extra leverage over that of Dr. Edmunds's. Side A B′ would not oppose this upward motion; but if the motion were a downward one, side P *c′* would not resist, as shown by arcs *c′* D, E F, G H, but A B′ would now oppose, and as the length A B′ is $1\frac{19}{32}$in. there is still $\frac{3}{32}$in. in my favour over surface A B in Dr. E.'s, or, if you combine surfaces A B and A C in Dr. E.'s, there would be little difference between the two. Now if B′ were the centre of variation, then for the upward motion, surface P C′ would resist, as shown by arcs I E, J G, L K, and R P; but surface B′ A would be inactive, if the motion tended the contrary way, the result would be vice versâ. If, however, the cone was of an angle of 90° (see dotted lines in Fig. 6), and A be taken as a centre of angular variation tending downwards, then, not only side A M, but also M P, would oppose, as shown by arcs M N and S O. Each of these sides are about 1⅜in. long, or about 2¾in., together equal 1¼in. in my favour, although, if looked at as a lever, this must be reduced to ⅜in. And, to avoid being misunderstood, allow me to say here that I do not bring forward these designs as the best that can be done, but only as illustrations of what could be done; and if it is the means of leading some inventive genius to hit on the right thing I shall feel myself more than repaid for my trouble. On p. 13 of No. 1041 William Granger suggests the very good plan of placing the screw between the two cylindrical surfaces, and in this method anticipates me in publication, although my drawings one to four were completed on 28th ult., and the design worked out some two months previous to that date. Now, glancing at Fig. 7, we see an illustration of my system 3, viz.: two cones in opposition to each other, and here we have one as much as 4in. diam., and the other 1½in. diam., with their conical surfaces on the same side at an angle of 90° to each other; this, of course, is not compulsory, but I shall say more on this subject when I come to Fig. 11. The smaller cone consists of a single screw thread of ¼in. pitch, out of which three alternate sixths have been removed, and thus necessitating the removal of similar and corresponding sixths in the chuck to those left on the mandrel; and this being a single screw chuck and mandrel, would only interlock when the proper fraction of screw in chuck was placed in the proper space in mandrel, as pointed out on p. 499 by "F. A. M." But this cutting out of sixths is not very necessary, and is only useful to save time, and is merely a development of the bayonet joint. Fig. 8 is an end view screw cone, part of Fig. 7, and shows the alternate sixths removed, and in order that this might interlock at any meridian, it would be necessary to have a triple threaded screw; this I have endeavoured to show in Fig. 9, illustrating my system No. 2—viz., a cone in opposition to a flat face, and to make it clearer, I give sections of screw-cone at commencement and termination of one-sixth of a complete turn of a triple-threaded screw of about 2¼in. pitch; this is represented as 4in. diam. and ⅜in. thick. Fig. 10 illustrates a simpler form of system, No. 2, being a thick face plate solid with mandrel, and having a coarse angular screw, to supply the cone, turned on its outside circumference.

We have seen the good and bad points of Fig. 6, and no doubt it will have struck some that if the surface P C′, instead of occupying its present position and direction, had been a prolongation of line A C′, it would much more effectually oppose the upward motion of variation about A as a centre, and in Fig. 11 with a base of only 1⅝in., and with a similar length for the sides, we get resisting lengths equal to the diagonals, or about 2⅜in. with a base of 2in.: this would equal resisting lengths of nearly 2⅞, and these figures are so favourable that really comment is unnecessary—if this principle be modified so as to become 4in. in diam. by only ¾in. long, we arrive at Fig. 12, where the diagonal system is still preserved, but the conicity of the surfaces so nearly approximates to the perpendicular that, although very useful for preventing angular variation, their value as a concentring means is almost *nil*. Similar unsatisfactory results would follow a very great prolongation of the length and diminution of diameter if the diagonal system be preserved, and yet by making the diameter of the base of mandrel nose equal to its length, or by starting with a square plan we find the diagonal system so successful, that I am inclined to think this form offers the greatest stability and the best corrective angles for a cone system, which also would be included in my system 8. The cones in this case would make an angle of 90° with each other on the same side, and 45° with the axis, and if these angles were applied to Fig. 12, as shown in dotted lines, it would then become a very efficient truing means both for face and centre; but it has struck me that the best angle might be one found by bisecting the angle made by the diagonal A B and A C as at A D. The following questions suggest themselves to me:—

(1) Is it as easy to make a male cone in hardened steel as a female cone in cast iron—say, as true as it is to make two rectangular surfaces, one of which is parallel to the axis, on hardened steel, and counterpart ones in cast iron?

(2) Can a screw of fine or coarse pitch and of square or angular thread, by any moderately cheap means, be made absolutely true, or true enough to answer as a centring means for ornamental lathe work.

I think two cones easier to make than four rectangular surfaces, and I also think it possible to make screws sufficiently true for the purpose named, but am looking for "Bow's" answer to Dr. E.'s questions on p. 562, and also want to see what he will say to letters 23945-6. It seems to me that if we are speaking scientifically of an object, we shall not be able to get on very well unless we give distinctive names to the different parts, and I do not see how the geographical nomenclature of Dr. Edmunds can be improved.

E. J. S.

The Laurels, Westbury-on-Trym.

[24028.]—WHY does not Mr. Wenham state the names of the manufacturers who have used diamonds (query, carbonado) to turn up hardened lathe mandrels or other process of hardened steel? This would stop Mr. Hines and others from making remarks and doubting his statement.

If diamond or carbonado will, as I believe, do all that is wanted in the way of cutting hardened steel, I should prefer to use it in preference to any number of emery wheels, for I cannot in my own mind get rid of the notion that emery wheels *may* leave some bits of emery (small they may be) *in* the steel.

No mechanic will, I think, say that a lap ever produces "truth." If so, then a wheel is best, unless a wheel is in its turn superseded by diamond or carbonado.

Z. Y. X.

### INTERCHANGEABLE MANDRELS.

[24029.]—As Dr. Edmunds says, vested interests of some lathe makers is very strong. I think the doctor is right in the course he is taking in advocating the change, and if he overcomes the vested interest, why, then, so much the more honour. Years since I felt very much the want of the "interchangeable" chuck arrangement.

If this plan is feasible, as I think it is, then a poor man (amateurs are often poor) can have first a good lathe made, and then from time to time have an additional chuck without having to part with his lathe-head for, say, a month. And, moreover, an amateur could go out to spend the evening with a friend, and take his chuck with him! This may seem nonsense, but it shows what could be done if the scheme is carried out. Then the friend would want to have a similar chuck, and so trade would go on and the art of turning also.

Z. Y. X.

### NEW MIDLAND ENGINES.

[24030.]—I HAVE been too busy to answer the reply of "A Disappointed Driver" to my note concerning these engines. Since reading his letter I have been more than ever convinced that these engines are not having their due at the hands of the drivers, and if "A Fireman" in a recent issue of "E. M." expresses the opinion of the driver he is under, it may be considered proof positive that at least one engine will always be behind time, for no good driver who intends to keep time will let down his steam to half the proper working pressure: experience will teach him, if he does not reason it beforehand, that this is not the way to get along.

I repeat the opinion I expressed, and tried to explain, that nothing more is wanted than to notch up the gear till no more steam is used than the boilers will comfortably supply. This is just how the engines were expected to work and the only way they can be expected to work; and to show to "A Fireman" how far the driver was from the right method when he run down to 60lb. pressure with full gear forward, I may state that steam cut off at ⅛ stroke and at 120lb. pressure gives about a quarter better results than running steam full stroke at 60lb. pressure, and is also very much easier to supply. I say emphatically that these big cylinders are not a mistake, and as soon as drivers fully recognise this fact and act up to it, these fine engines, against which there seems to be so much prejudice, will become favourites with the drivers, and we shall hear no more of their not being up to their work, but have a good name all along the line.

I am aware that a good distribution at all points of the links alike is a difficult matter; when near mid-gear the valve is likely to throttle both steam and exhaust, and the man that invents a valve that gives a good opening with an early and rapid cut-off, a clear exhaust, and without any extra complications, will gain the lasting gratitude of railway engineers throughout the world.

I notice that Mr. Webb, on the L. and N.W., uses the Allen-Trick valve on his compounds, and this valve is no doubt a great advantage where an early cut-off is desired. I think this is worth more attention than it receives, and in conjunction with Joy's gear forms the best combination at present in use on locomotives.

I should like to hear something more of the experience of engineers with regard to balanced valves for locomotives. I believe they have been tried without much success. Can any readers of "E.M." state why? There is no doubt a balanced valve would lead to a considerable saving, not only in fuel, but also in repairs and lubricants.

Messrs. Alex. Wilson and Co. have been very successful in the application of Dayton and Wilson's patent balanced valve to marine engines. In one instance the bottom strap of the eccentrics still showed the marks of the tool after two years' wear, so easily was the slide moved. If such a result is possible in marine engines, why not with locomotives?

Will some of our friends who are drivers kindly give their experience on the following?

In starting a train the usual method is to put the gear fully forward and open the regulator just as much as she will take without causing the wheels to slip. Sometimes it is a very difficult matter to adjust the regulator so as to get a good start without slipping, especially when the rails are greasy. Now, I think that as soon as the engines begin to move, the best way is to put the gear to near the centre, open the regulator wide, and gradually set forward the gear to suitable position to full speed forward. The tendency to slip would not be great when the gear is near the middle, for although the steam pressure at the beginning of the stroke is great, the cut-off being early, the steam would expand, and the pressure immediately decrease as the piston advanced. Of course, this is only possible with screw or steam-reversing gear.

Luton, March 16. Helvellyn.

[24031.]—HAS not "Fireman" given us the truth respecting new Midland Engines? They seem to be designed with large cylinders and early cut-off so as to work very expansively, and yet have a large reserve of power for emergency. Instead of giving her all the pressure of steam, and notching up to speed required, "Fireman" says the regulator is open *three-quarters*, thus throttling steam before it gets to the cylinder, and requiring the lever to be put further over to get the speed. How can these engines be expected to do what is required of them under such conditions? The only wonder is that the result was not much worse.

Vortex.

### CONTINUOUS BRAKES.

[24032.]—UNDER the heading of "Scientific News," page 556 of last volume, reference was made to a new or improved vacuum brake introduced on the Midland Railway on Monday, Feb. 16. The circular of instructions for working the brake has been sent to me from Derby, and is herewith inclosed for the information of your readers.

It is satisfactory to find that at last the Midland Railway Company has become aware of the dangerous character of the "two-minute" brake; but it is to be deplored that when making a change something better than the new appliance has not been adopted. On and since Feb. 16 I have ridden upon several occasions with trains fitted with this brake, and find it slow in action, compared with air pressure. It is also very inconvenient that when an engine is changed, or shunting performed, the brake goes on, and has to be released by hand on each vehicle. Difficulties have quickly become apparent in releasing the brake. For instance, on Feb. 20, the 10.35 a.m. train from Leicester to Bradford was delayed a minute and a half at Sileby, and five and a half minutes at Barrow, as the brake would not come off. The piston rod packing is now new and in good order; yet some leakage takes place. What, then, may be expected in the course of a year or two?

Clement E. Stretton,
Hon. Mem. A.S.R.S., Leicester.

[CIRCULAR.]

"MIDLAND RAILWAY: THE AUTOMATIC VACUUM BRAKE WITH BALL VALVE.—This brake can be applied throughout the train by the driver from his engine, or the guard from his van. Engine-driver's instructions: Before starting from any station see that your gauge indicates at least 18in. of vacuum, and that not less than this amount is maintained during the journey and while standing at stations. To apply the brakes, open the air-valve on the engine. To release the brakes, close the air-valve and restore the vacuum to the same amount as it existed before their application. When the engine is attached to the train and the brake-pipes connected, put on the small ejector, and keep it on to maintain a constant vacuum during the journey. The large ejector may be used to raise a vacuum rapidly, or when the brakes require to be taken off again quickly; but in either case it must be closed again gradually. Guard's instructions: To apply the brake, lift up the lever of the valve. This admits air throughout the train pipe, and is to be only employed in cases of emergency. This valve opens automatically when the brake is applied with full force by the driver, and insures rapid action. See that all pipes between carriages are properly coupled together, and that the couplings on the end coaches are placed upon the stop plugs. See by your gauge that a vacuum of 18in. is maintained, and report if otherwise to the driver. General instructions: To release the brakes for shunting purposes—the engine having left the train—first see the hose coupling at one end of the train is off the stop-plug, and then pull the cord which is fixed under the frame of each carriage. This admits air to the top side of the cylinder and the brakes come off by gravity.

"Derby, Feb. 12, 1885. JOHN NOBLE."

### ACCELERATION OF TRAINS, BRAKES, &c.

[24033.]—A FEW days ago the Postmaster-General stated, in answer to some inquiry in the House, that there was in contemplation a considerable acceleration of the mail service between Yorkshire and the Continent. At present the Continental mails arrive at Charing-cross at 6 a.m., and are forwarded to Leeds by G.N. train at 9 a.m., arrive at Leeds 1.50 p.m., and, as the mails for transmission by the 7.40 p.m. Dover express from London leave Leeds at 1.10 p.m., it has been impossible to answer letters by return. On and after July 1, the Postmaster observes, the mails will arrive at Leeds about 11.40 a.m., and leave about three hours later. This points to a very substantial acceleration of trains on the G.N.R. Can any correspondent give us more particulars?

A striking feature of chairmen's reports at the recent meetings of railway companies has been the gradual but sure decrease of second-class traffic, and the chairman of the G.N.R., Lord Colville, unmistakably hinted that the example afforded by the M.R. many years ago will be imitated, and second-class abolished altogether for through traffic. It certainly seems as if there were a great waste of energy entailed in hauling about the country empty second-class vehicles, for, from my own personal observation, it has seemed as though the proper way to "make up" a train, such as, say, the 9 a.m. Paddington to Penzance, would be in the proportion of one first-class to four third-class coaches.

It is generally painful to see in how great a degree prejudice still reigns in the bosoms of directors. Just recently we read that the G.N. and M.S. and L.R. have decided to adopt the automatic form, being thereto influenced by the recent Penistone accident. How much better it would have been for these companies to have come to this decision *before* that lamentable occurrence. There is the North-Western, too, hovering about in a hesitating, lame sort of way between the adoption of various brakes, all of them more or less inefficient, and waiting, probably, for same serious accident to happen before deciding in favour of any of them.

A great deal seems to be made by the opponents of the Westinghouse brake of the fact that more failures occur in proportion to the miles run than in the use of the various vacuum brakes. Even if this be the case, can anyone say if in *all* such failures as many lives have been sacrificed as in the one failure of the vacuum at Penistone?

The worst that happens, in case of a Westinghouse failure, is a stoppage of the train, and, with a block, well-worked, an accident would be impossible; in fact, the word failure is inapplicable; it is simply "an excess of zeal" on the part of the brake.

Can any correspondent say whether the extra metals for narrow-gauge trains are laid beyond Bristol, and, if so, how far? I believe, however, that from Bristol to Penzance is wholly broad gauge.

Also, I should like to know what is the peculiar advantage of the longitudinal sleeper v. hollow rail, such as the G.N.R. use over nearly all their system above the usual reversible rail? Does it mean smoother running, or more economical working? Perhaps some reader could supply us with a sketch of the G.W. broad-gauge engine. I have looked through all past vols. and no such drawing has yet appeared. The only G.W. engines illustrated are the 7ft. single and the old B. and E. 9ft. tanks. If any of your readers want a really fast run let them note the speeds attained by the Midland London to Leeds expresses between Dronfield and Heeley Stations near Sheffield (down trains), especially through Ecclesball Station.

So much ridicule has been cast upon accounts of apocryphal speeds which have occasionally appeared in your columns that I am not going to attempt to estimate the speed; but I should like to know if someone of experience ever has done so, and, if not, if they would, and give it to us.

**John F. Lawrence, B.A.**

Merton Coll., Oxon.

### BORT.

[24034.]—THAT Bort dust, like diamond dust (the two being really convertible terms), and also Carbonado dust, may be adulterated, goes, in these days, without asking.

Carbonado for use ought to be the *small* pieces found with diamonds in Brazil, and not the fragments of a large piece of carbonado. The original outer skin formed by Nature is best.

What is "*Dessau Nickel Diamondiferous?*" The name takes one's breath away. When Dr. Edmunds speaks of "clear, transparent, diamond crystals," on the surface of a tool made of the above, is he not unwarily confusing the part of a crystalline body, or of a crystal, with the crystal itself?

Z. Y. X.

## REPLIES TO QUERIES.

⁂ *In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[55384.]—**American Organ Reeds.**—With reference to the question about the smaller scale reeds, I have recently had an opportunity of measuring specimens of three different makers' work, and the following figures may be useful to your readers. The reeds chosen for measurement were all mid. C. The first was of that make in which the vibrator is clamped to the block by the brass of the latter being driven through on each side of the heel and burred over it; the second had the brass of the block driven through in the shape of a square or diamond rivet and burred over the hole in the vibrator heel; the third was the plain iron rivet. In the case of No. 1, the length of the block over all is 2·1in., of the slot through which the tongue vibrates, 1·1in.; No. 2 has the block a trifle longer, 2·15in., and the slot corresponds 1·15in.; No. 3, or the common iron rivet reed, is 2·25in. long over block, and 1·25 in the slot. They thus all preserve similar proportions for the standard set of reeds giving the diapason tone. Then a reed was taken from an organette, the same make as No. 3, that is, common iron rivet; it is 1·9in. over block, and the slot is 1·15in. long. It is evident that the vibrating length of mid. C must be over an inch to obtain good results, for breadth and thickness of vibrator are confined within narrow limits, except, of course, for special reeds.—FLIEGEN.

[55384.]—**American Organ.**—Mr. Fryer (page 37) still seems to be "up in the clouds" with regard to the matter of placing 8ft. reeds into cavities originally intended for 16ft. reeds, but which have been planed off to suit 8ft. reeds. Because I told a querist he could do this, and so utilise a 16ft. solo set tubeboard for the job he contemplated, Mr. Fryer has ever since been discoursing on the folly of placing 8ft. reeds in 16ft. tubes. May I ask Mr. Fryer to again read my former explanation on page 501 last vol., and also "Fliegen's" remarks on page 37? If he then fails to comprehend the matter, I would respectfully advise him to think it over, and try a few experiments, and not again occupy valuable space in discussing what must be quite clear to other correspondents. Mr. Fryer should also look up "Joiner's" description of his two-manual organ, which appeared in a back vol.; he will there find a little variety of tube dimensions, and I can assure him, from personal inspection, that that instrument did not "talk nonsense"; on the contrary, there was a pleasing variety of tone, such as is not generally found in similar instruments. Mr. Fryer seems to take it for granted that the theoretical notions I alluded to were his.—J. E. FLOYD.

[55571.]—**Turbine.**—A draft tube will work inclined; but the first foot or two should be perpendicular, and the shaft of the wheel also; this to prevent the step wearing sideways, and the wheel binding in its case and permitting leakage. Keep in view that the column of water below the wheel is practically suspended upon it, and that a column of 20ft. by 10in. diameter means, without wheel and shaft, about 1,000lb.—a serious item of friction to provide for—and if the gate is not made to close very slowly, this pull is intensified enormously in checking suddenly the column in motion. I have several turbine manufacturers' pamphlets. Most provide and calculate on the use of a draft tube where necessary; none recommend them otherwise. Except to the extent of keeping the wheel above tail water for inspection and cleaning, my own experience and observation is in perfect accord with this.—MILLWRIGHT.

[55827.]—**Gravity and Dead Escapements.**—I am pleased to see the correspondence on this subject which has appeared in "Ours"; the more so because I had just decided on the dead-beat for a regulator I purpose making. Some few years back I made a gravity regulator with lantern pinions of 12 and 10, and a 30lb. pendulum, zinc tube compensation. This clock has gone well so long as it is kept clean, and the oil fresh; as soon as it gets a little stiff it fails sometimes to lift the pallets, although the weight is a heavy one. I am decidedly of opinion that the train for a gravity regulator should be as fine and as good as for a dead-beat; and I should also want to be paid more for a gravity clock than for a dead-beat of equal finish. Beside the objection of the heavy weight required, and its effect on the longevity of the clock, the gravity escapement, to my eye, has a very cranky appearance, if lightly made, as it should be; also its shaky double beat is not desirable in a regulator. The place for these escapements is without doubt in turret and church clocks, for which they secure an excellent rate, if correctly made. For some years I have had charge of a fine church quarter clock with gravity escapement by Gillet and Bland, and its performance has been all that one could desire. I, however, take care to keep the escapement clean and fresh oiled, and for this purpose usually visit it once a month. It has often gone for several consecutive months without requiring alteration. The pendulum is plain wood rod, and beats 1½sec. I note that Mr. Glasgow in his late addition to horological literature is also in favour of the dead escapement for regulators; and Sir Edmund himself, see page 16, admits that it is as good as some others he mentions. Does any correspondent know anything respecting the suitability of aluminium bronze for dead-beat 'scape wheels—its durability, effect on the oil. &c.? Perhaps Sir E. Beckett will oblige.—J. E. FLOYD.

[55876.]—**Improving Light in Coal Gas.**—Your idea would, no doubt, be an improvement for capillary attraction if required, as is the case with heavier bodies, such as paraffin and colza oil, but not in this. The benzol being very volatile, gives off its gas very easily, and this rising is taken up by the gas passing through carburetter. You will not want to put spirit in oftener than from 7 to 10 days, for you will see, by experience, if you keep the taps turned off constantly when not in use, the spirit will be retained, so to speak, in the carburetter. Of course you can make it any size you like, but I have given one for from 10 to 20 flat-flame burners, the Argand being very little in common use. You never need fear the cotton wool becoming too dense for the reason given above.—ARVONIA.

[55902.]—**Irish Land Act.**—Any Parliamentary papers which have been "ordered to be printed" can be obtained of Hansard, Great Queen-street, W.C.; the Queen's printers, East Harding-street, E.C.; or of Harrison, St. Martin's-lane, W.C. There are also booksellers in all the chief towns who either keep on sale or procure any Act or Parliamentary paper that has been published.—C. T.

[55915.]—**Inhabited House Duty.**—"Chelsea" can pay the demand under protest, and then appeal to the Commissioners at Somerset House in writing. As he states the case he ought to pay only 6d. in the pound; but does the tenant of the shop pay the rates and taxes?—LIMB O' TH' LAW.

[55916.]—**Battery for Sewing-Machine Motor.**—"Stitching Machine" should have six cells with zincs in each of not less than 5in. by 3in. within the liquid, or in all 30 sq. in. of zinc surface, with carbon on either side and about ⅜in. distant. Each carbon should not be less in area than the zinc, but may with advantage be considerably larger. Charge with a solution of potassium bichromate, 3 parts; sulphuric acid (strong), 9 parts; and water, 20 parts; or, to partially prevent local action on zinc, 25 to 30 parts of water, all parts by weight. Mr. Lee, who advertises in this journal, has lately introduced an entirely new bichromate salt which has every advantage as compared with the bichromate of potash. 1st. It is soluble in its own weight of cold water. 2nd. It contains more chromic acid than the ordinary bichromate or potash. 3rd. It is cheaper. 4th. It does more work. And 5th. It does not crystallise on the carbons or in the cell. I have in my house such a battery that was charged last December, and thoroughly fulfils what I have above stated.—JOHN E. CHASTER.

[55942.]—**Dry Battery.**—"F. W. L." will do well to discard the use of sal-ammoniac, and use a rather strong solution of zinc chloride. The action in the battery when using sal-ammoniac resolves itself ultimately into the De la Rue chloride of silver battery, with a solution of $ZnCl_2$. The disadvantages in using sal-ammoniac are those complained of—viz., abundance of gas evolved, and also there is more local action at the zinc when left on open circuit. It is necessary to have a small aperture in the top, if only a pinhole. There is also an advantage in using chloride of zinc solution in place of sal-am. sol., and that is, there is no tendency to creep.—JOHN E. CHASTER.

[55981.] — **Oxidation of Carbon in a Galvanic Cell.**—"Quæsitor" asks if an efficient battery has been made by using a platinum-carbon couple in fused caustic alkali or nitrates of the alkalies. It has been sufficiently demonstrated by experiment that the cost of keeping the caustic or nitrate of the alkali fused by means of gas is quite prohibitory, apart from the consumption of the carbon element and chemicals. If a coke fire be substituted for the gas, the cost and trouble of attention is out of all proportion for the current obtained, as compared with batteries of the Bunsen and bichromate type. When using fused nitrates of the alkalies, the clouds of dense and poisonous fumes of the lower oxides of nitrogen arising, apart from the danger of having such a compound near a fire, is at once sufficient to condemn a battery in which they are used. Jablochkoff has described a battery in which plates of carbon and iron are placed in fused nitre, the carbon being rapidly consumed. This battery which I believe had its nativity in Paris, has been likewise buried there, not having sufficient vitality for its existence. —JOHN E. CHASTER.

[55982.]—**The Zinc-Iron Cell.**—Using iron as either the positive or negative pole in any battery gives low E.M.F. Take Mr. Sprague's list of the cost of battery working, Table VI., and it will be noticed that the E.M.F. of Slater's iron battery (which is merely iron replacing the zinc of a Bunsen) is 1·1 volt, as against 1·6 for the Bunsen, or about 40 per cent. less. In the Lalande and Chaperon cell, in which iron is the negative element, the available E.M.F. is stated by those interested in the company as being 0·7 volt, though I cannot obtain more than 0·6; merely a difference of 15 per cent. Respecting this loudly vaunted cell, of which I have had too much experience, seeing the almost worthlessness of it from a practical point, I shall have something to say about it within these pages very shortly. If "Noad" uses the term "surprising intensity" as being the intensity I, as written by some electricians, and meaning quantity of current or C, that statement goes for nothing, as a single cell of any sort might be constructed to give 1,000 ampères. If, on the other hand, he means E.M.F., he is wrong, and Mr. Sprague quite right. The indefinite term of intensity, as a measure of electricity, requires altering. It might not be out of place to state here that whatever Mr. Sprague states in his book is quite correct, as I have verified from time to time, and he is one of the few writers we have who prefers to make his own observations before committing them to print. He is one of the most valuable contributors we have to this journal, whether under his own name or that of "Sigma," and well remembers to carry out what Montaigne would have us learn, and which appears weekly quoted as a prefix to Letters to the Editor.—JOHN E. CHASTER.

[55987.]—**Zinc.**—To "R. W. J."—Surely the best zinc of commerce is sufficiently impure for battery purposes, without seeking to render it still worse. Whatever you mix with it will tend to destroy its value for using in a battery. Rolling it cold, as suggested by "Dens," is impossible. Prof. Bloxam, on the manufacture of zinc, states:—"Rolling of Zinc into Sheets.—Before the year 1812 zinc was used almost exclusively for the manufacture of brass, since it is brittle both at the ordinare temperature and at high temperatures; but it was then discovered that a temperature between 200° and 250° F. rendered it malleable and capable of being rolled into thin sheets. For this purpose, however, it is necessary that the zinc should not contain iron or lead, the former of which it acquires when re-melted in iron pots, while the lead is carried over in the distillation of the zinc, in consequence of the presence of galena (sulphuret of lead) in the ore. To prepare the zinc for rolling the ingots of spelter are remelted upon the fireclay hearth of a reverberatory furnace, which is made to slope down to a deep cavity or sump at one end, into which the melted zinc flows. Lead (specific gravity 11·4) being much heavier than zinc (specific gravity 6·9), and the two metals having very little disposition to alloy with each other, the bulk of the lead settles down to the bottom of the cavity so that the upper portion of the melted metal is comparatively free from lead. It is then ladled out and cast into ingots of convenient size for rolling, and after these have been again heated to about 250° F. by the waste heat of the furnace, they are passed between cast-iron rollers and reduced to the required degree of thinness."—JOHN E. CHASTER.

[56008.]—**Bichromate Cell.**—"Anglo-Dane" will find in time that the lead lining for battery cell, using bichromate solution, will be eaten through. As the action is not rapid, there may be instances when its employment might be advantageous. The joints must be "burnt" and not soldered, as the solution attacks solder. (See also reply to 55986.) —JOHN E. CHASTER.

[56014].—**Internal Gear Wheels.**—Alas! my friend, I do not understand you. "Pitch of large wheel is 4⅞in. with 48 teeth. Pitch of small wheel is 4¼in with 44 teeth. Length of large wheel is ¼in. bare." What can this mean? The pitch is the distance from centre to centre of tooth, measured on the pitch line. Do you mean that you are trying to get a wheel of 4⅞in. pitch to work with one of 4¼in.? I cannot think you mean that, yet I am unable to read your query any other way. For, assuming that you mean pitch diameter instead of pitch, it is clearly impossible for an internal pinion of 4¼in. diameter to gear with an internal ring of 4⅞in. If these were pitch diameters in ordinary wheels, the number of teeth would work out to $\frac{5}{16}$in. pitch, but teeth of such pitches would be cut by machine with straight flanks and rounding points. If the pitches were 4⅞ or 4¼, the following proportions would be suitable:—

Length of tooth above p. line = $\frac{5\frac{1}{2}}{15}$ths of pitch.

" " below " = $\frac{6\frac{1}{4}}{15}$hs "

Thickness of tooth = $\frac{7}{15}$ths "

The tooth flanks may be struck with rolling circles —a point in a generating circle rolling upon the pitch line forming the curves of the tooth flanks and faces—the circle never to be smaller than the radius of the smallest wheel of a set. The same circle which strikes the points of one wheel must strike the roots of the pinion which works with it, and *vice versâ*. The whole subject was fully described on pp. 99 and 143 of the ENGLISH MECHANIC, Vol. XXXVII. I trust I shall not give offence to any of my fellow subscribers in what I say; but I cannot help thinking that much disappointment and irritation would often be avoided if querists were more exact in their choice of terms and definitions. I have repeatedly seen questions put in these columns which nobody could possibly answer satisfactorily. Of course querists themselves know what they want, but in the absence of correct definition they should not be chagrined because others fail to understand their wants. If a question is deemed worth answering, it is surely worth the querist's, while to put it as clearly as words will express it.—J.H.

[56025.]—**Trueing Grindstone.**—If "Z.Y.X." reads my reply carefully, he will see that I ask no question whatever—I only state facts; but I am very much interested in his emery-wheel turning. It will sometimes happen that we require a round or hollow face to the emery wheel, and this in the ordinary way requires a diamond; suggestions are not sufficient. Will "Z. Y. X." therefore give a full explanation, sufficiently clear to enable those who are quite unacquainted with the subject to understand how the bort or carbonado (the action being more important than the name) is set?—is the turning done wet or dry—at what speed—where can the carbonado be obtained—its selection, price, &c.? I am sure the subject is of general interest. I once obtained some pieces from a china mender. I considered them only fragments of emery, as I could not get my settings to stand for turning; diamonds are far too expensive for workshop use, and a cheaper substitute would be a boon to many readers of the—E. M.

[56038.]—**Restringing Grand Piano.**—If there are no holes in the wrest pins, replace with a new set of drilled ones; they are cheap enough. It is a difficult matter to get the wire to bind tight enough on wrest pins that are not drilled. You will save time, and evidently a deal of trouble, by taking the advice now offered. If you experience any difficulty afterwards, write again, and I will help you all I possibly can in the way of writing. It requires a little practice before anyone can put a string on neatly. See that the coils of wire round wrest pins are close together; but do not let the coils overlap each other.—G. FRYER.

[56040.]—**Knocking in Gas-Engine.**—I was in same fix as you, and examined crank brasses and found no play, same at coupling of connecting-rod to piston, then the flywheel, and found it apparently tight; thinking the key might be tight sideways, I hammered it in very tightly, and that cured it. Mine is a 3½ h.p. Otto.—SAMUEL SHAW.

[56041.]—**Gun-metal.**—Alloys known as gun-metal, or by the names of their patentees, contain copper, zinc, tin, and iron—always two of those metals, very often three, and occasionally four. Most of those containing iron are, or have been, the subjects of patents I believe. I do not apprehend the difficulty of "Z. Y. X." The metals are not always "melted together," but are mixed together when in the molten state. Unquestionably some difficulty is experienced then, owing to the different temperatures of the melting points; but when copper and zinc are mixed together and called brass, those who do the mixing take special precautions not to lose any more zinc than they can help. Some alloys are very complex in their character; for instance, a maillechort, or German silver, patented many years ago, had a composition as follows: Copper 55, nickel 23, zinc 17, iron 3, and tin 2; the Chinese packfong, or white copper, has a composition of nickel 31·6, copper 10·4, iron 2·6, but it must not be assumed that these metals are put into the melting pot in the cold state and melted together. Very often, when it is desired to produce a mixture of copper, zinc, and tin, old brass would be used to give the copper and zinc, and so when it is desired to add iron, the latter would probably be melted before it was added to the molten brass. If "Z. Y. X." will look through his back volumes I have no doubt he will find descriptions of patented alloys which are quite as complex as any I have mentioned above; and if he will put some definite question, I will endeavour to give a description of the order of mixing the metals—always providing the answer is likely to be of service to my brother readers.—NUN. DOR.

[56053.]—**Singing Noises in the Head.**—What I said with regard to this query was that a person had lost it after becoming an abstainer from flesh. I see someone answered it on p. 41, and then threw some mud at me. If he can find anything wrong with any of my answers, let him criticise them at once in his most severe style. But to abuse is no argument. As far as possible, I answer questions relating to my own work, and do not rush in where my knowledge is inferior. Would that other correspondents would do likewise!—T. R. ALLINSON, L R.C.P.

[56071.]—**L. and N. W. Engines.**—Thanks; but the 6ft. 6in. are quite a different class. As there are about 80 of Ramsbottom's 6ft., it is strange you should never have heard of them. There are a few of Webb's of the same dimensions as well. W. B. P.

[56080].—**Helical Teeth.**—I trust the following will be an answer to the questions put by "Athos." Helical gear should differ in no respect from ordinary gear in regard to proportions. The teeth sections struck at right angles to their axes in any given portions will be the same as those for ordinary gear, and will be struck accordingly either by rolling circles, or by the odontograph scale. But as the teeth require to be marked out upon their ends, and as these ends are cut to the angle of the obliquity of the helix, the section at right angles would not give the correct lines for the ends. Hence the simplest practical method of getting the shape thereon, is to strike out the teeth first in the ordinary way, and to make one tooth as though for an ordinary spur wheel, and then to cut it across the end to the angle required (Fig. 1), and from the section thus produced obtain the width and the striking lines. In the case of the 60-toothed wheel of 5in. pitch which you instance, the dimensions are as follows:—The length of the tooth above pitch line is 1¾in., below pitch line 2in., the thickness on the pitch line is 2⅜in., and by using the Odontograph scale, the striking radii, and their centres come as shown by the full lines in Fig. 2. Cutting off the end of the tooth to an angle of 65°, the apparent thickness on the pitch line is increased to 2⅝in. Then, though the same radii may be employed, their centres require to be moved above and below these used for the normal section, to the positions shown by the dotted lines, and from these new centres and to the increased width the ends of the teeth are struck. Now if this wheel happened to be one of small diameter and pitch, and a pattern were to be made, the way to do so would be to cut the teeth out of the solid, the pattern being jointed in the centre. Thus if the pattern were 5in. deep, it would be jointed in two thicknesses of 2½in. each, held together by a couple of loose dowels, so that the teeth once worked could not shift around from their relative positions, and the teeth would be pitched out on the top and bottom faces and in the joint faces to the increased width, and from the new centres obtained by cutting the templet tooth to the angle of the helix. Then a slip of paper, equal in length to the circumference, and having lines equally pitched out, and corresponding with the tooth points; drawn diagonally across it to the angle of the helix—will be glued round to afford guidance for the templet (Fig. 3), which is used for working out the inter-tooth spaces. If the wheel were too large to be made of solid stuff, the rim would be built up in the usual way, and the tooth blocks fitted and glued on in the rough, and their faces turned and pitched out as before on top and bottom and in joint. But, instead of paper, a strip of thin straight steel (a clock spring for example) would be curved around the points of the teeth, and its edge would form the guide by which the lines representing the width of the teeth at the points, would be drawn across from the curves struck upon one face to those on the other. The teeth as before should be worked to these lines by templet. If the wheel is so large in diameter that the arc of the circle which is embraced by the length of the tooth, when laid at its diagonal position, shows no appreciable amount of curve, then there is no need to work the teeth in place at all, but simply to plane them up as straight teeth, and put them on at their angle. This effects a great saving of time, and may always be adopted in the case of large or of shallow wheels. In all such pattern wheels jointing is necessary through the centre, and there is little difficulty in moulding, the halves being screwed out, precisely as in the case of angle wheels, or wheels whose teeth are at an angle of 45°, the moulder simply drawing out the pattern in the direction which his sense of touch tells him is the line of least resistance of the sand. A trifle of taper of course is put in the teeth. The same remarks as to marking out with a bent steel apply to the blocks for machine-moulded wheels, but they are not jointed in the centre, because the horizontal arm of the machine is drawn backwards instead of upwards. Neither are they necessarily jointed along the central plane of the wheel in a core box, although it is better to do so for convenience of marking out and working, even if they be fastened together afterwards. But in the hands of a careful workman, the top lines are sufficient guide to the templet. Fig. 4 shows how this box is made, and is almost self-explanatory. The front side is removed to show the teeth. We have therefore ends A A, with their blocking-up angle pieces B B, sides C, one only being in place, and the tooth blocks D D jointed in two pieces at *a*, this jointing being necessary where the curve of the wheel radius is so great that the outer flanks of the extreme teeth would, by their leaning over, tear the sand up. There are five teeth shown in this box, making twelve cores for the wheel of 60 teeth. If you were to put ten teeth in the box, probably two joints would be necessitated. The bottoms of these blocks are planed flush with the ends of the pieces A, A, and rest directly on the core maker's bench without being screwed to the sides. It is not necessary that the angle ends partake of the twist of the teeth, so long as the half-tooth at one end of the box is an exact supplement of that in the opposite end. In ordinary spur gear, too, the teeth are usually jointed along one edge, to prevent the joints of the cores from showing in the casting, so that the tooth segment at one end of the box has one half the thickness plus one half the width on the point, while at the opposite end the supplementary segment has one half the width minus one half the width at the point. In the case of a helical wheel, if the tooth has much twist upon it, joint approximately down the centre; if little or none, joint at the edge, as in ordinary gear. Of course the ends A A of the box must converge exactly to the centre of the wheel; else the cores will not match, and the angles of the blocking pieces B B must match. The making of wheels in core boxes like this has become almost obsolete, except in the case of those of very large diameter, owing to the almost universal employment of the wheel moulding machines.—J. H.

FIG. 3.

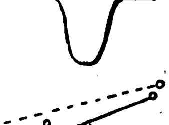

FIG. 2.

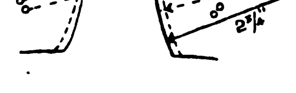

FIG. 4.

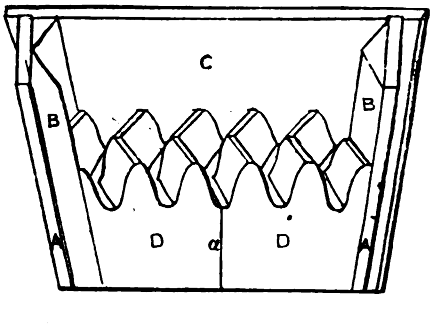


[56089.]—**Fasting and the Jews.**—The Jews do not abstain altogether from either food or drink one day a week, so that "S." will require to look somewhere else for the cause of their health and long life. Their hygienic laws are excellent; but the rite of circumcision has more to do with their immunity from disease than anything else. Passover cakes are biscuits about 8in. in diameter, but so thin that they will hardly hold together; they are made without leaven, and taste exactly like our common water biscuits.—B.Sc., Plymouth.

[56097.]—**Conics.**—Let P, Q, R be points on a parabola whose vertex is A, and latus rectum $4a$. Let $Pa$, $Qb$, $Rc$ be tangents at these points, cutting axis in $a$, $b$, $c$, and let the tangents of the angles they make with the axis be in harmonical progression. Let the tangents at Q and R cut in E, those at R and P in F, those at P and Q in G. Let PL, QM, RN be ordinates. Then $\frac{PL}{aL}, \frac{QM}{bM}, \frac{RN}{cN}$ are in H P. $\therefore \frac{aL}{PL}, \frac{bM}{QM}, \frac{cN}{RN}$ are in A P. $\therefore$ Also, since $aL = 2AL$, $bM = 2AM$ and $cN = 2AN$, we may put $\frac{2AL}{PL} = p - m$, $\frac{2AM}{QM} = p$, $\frac{2AN}{RN} = p + m$. Now, area of $\triangle EFG = \triangle aGb + \triangle bEc - \triangle aFc$. $\triangle aGb = \frac{1}{2} . Ab . \frac{PL + QM}{2}$. Since G is equidistant from diameters through P and Q. $\therefore \triangle aGb = \frac{1}{4} (AM - AL)(PL + QM) = \frac{1}{4}\left(\frac{QM^2}{4a} - \frac{PL^2}{4a}\right)(PL + QM) = \frac{1}{16a}(QM + PL)^2 (QM - PL)$ &c.

$$\therefore \triangle EFG = \frac{1}{16a}\left[(QM + PL)^2 (QM - PL) + (RN + QM)^2 (RN - QM) + (PL + RN)^2 (PL + RN)\right].$$

$$\text{But } p - m = \frac{2AL}{PL} = \frac{2 . PL^2}{PL . 4a} = \frac{PL}{2a}$$

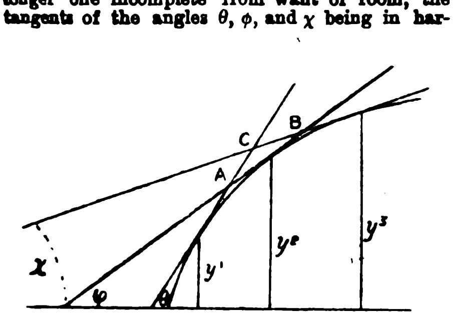
$$p = \frac{QM}{2a},\ p + m = \frac{RN}{2a}$$

$$\therefore \triangle EFG = \frac{(2a)^3}{16a}\left[(2p - m)^2 . m + (2p + m)^2 . m + (2p)^2 . (2m)\right]$$

$$= \frac{a^2 m}{2} . \left[4p^2 - 4pm + m^2 + 4p^2 + 4pm + m^2 - 8p^2\right] = a^2 m^3.$$

A result independent of the position of the points P, Q, R, provided the harmonical progression be constant. — E. J. L., 4, Clevedon-terrace, Rochester.

[56097.]—**Conics.**—The figure represents a parabola with three tangents meeting the axis, the longer one incomplete from want of room, the tangents of the angles $\theta$, $\phi$, and $\chi$ being in harmonic progression, it is required to find the area of the triangle A B C; now when three numbers are in harmonic progression, their reciprocals are in arithmetical progression, consequently the co-tangents of the three angles are in arithmetical progression. The equation to the parabola, the origin being at the vertex, is $y = \sqrt{4ax}$, $a$ being distance from vertex to focus; differentiating, we find $\frac{dy}{dx} = \sqrt{\frac{a}{x}}$ or $\frac{2a}{y}$, the latter being the simpler expression, will be used in what follows: as the diff. co-efficient at any point $x_1 y$ = the trig. tangent of the angle of inclination of the line touching the parabola at that point, we get tan. $\theta = \frac{2a}{y}$, and so on for the other two angles; then inverting the last expression we get cot. $\theta = \frac{y_1}{2a}$ we have, therefore, $\frac{y_3}{2a}$, $\frac{y_2}{2a}$, and $\frac{y_1}{2a}$ in arithmetical progression. Now suppose $b$ to be the common difference, we have $\frac{y_3}{2a}$, $\frac{y_3}{2a} - b$, $\frac{y_3}{2a} - 2b$ representing the co-tangents of $\chi$, $\phi$, and $\theta$, or calling $y_3 = c$ and inverting, we have the tangents of these angles $= \frac{2a}{c}$, $\frac{2a}{c - 2ab}$, and $\frac{2a}{c - 4ab}$ respectively, these being equated to the diff. co-efficients $\frac{2a}{y_3}$, $\frac{2a}{y_2}$, $\frac{2a}{y_1}$, we get $y_3 = c$, $y_2 = c - 2ab$, $y_1 = c - 4ab$. The general equation to the tangent to a curve is $y^1 - y = \frac{dy}{dx}(x^1 - x)$, $y^1$ and $x^1$ being the ordinates of the straight line, and $y$ and $x$ being those of the point of contact; hence our three straight lines touching the parabola will be represented by three equations of this form, and in each of the three we must substitute one of the values of the tangents found above, and also the corresponding values of the ordinates found above. We can then find the ordinates of the two points of intersection which are at the ends of the base A B of our triangle, and thus we can calculate the length of that base. We must now calculate the angles A, B, and C, referring to "Euclid," Book I. Props. xv. and xxxii., we find that $A = \theta - \phi$; $B = \phi - \chi$; $C = 180^\circ - (\theta - \chi)$. Now $\theta = \tan.^{-1} \frac{2a}{C - 4ab}$ and $\phi = \tan.^{-1} \frac{2a}{c - 2ab}$. Now in order to get sin. A, we must have recourse to a trig. formula. Let $m$ and $n$ be any two numbers, then sin. $(\tan.^{-1} m - \tan.^{-1} n) = \frac{m - n}{\sqrt{(1 + m^2)\ (1 + n^2)}}$ putting $\frac{2a}{c - 4ab}$ and $\frac{2a}{c - 2ab}$ for $m$ and $n$, we get the value of sin. A, and similarly we can get an expression for sin. B and sin. C. The formula for the area of a triangle suitable to our purpose is area $= \frac{(AB)^2}{2} \frac{\sin. A . \sin. B}{\sin. C}$, the value of A B having been found as above, and the values of the three sines being substituted in this formula, it will be found that everything cancels out, leaving only area $= a^2 b^3$, which is a very neat result after all our labour, where $b$ is the common difference between the co-tangents. Were I to re-write this paper, I would reverse the order of the co-tangents, making cot. $\theta$ the first term in the progression, and $y_1 = c$, so that $b$ would be positive; however, the result is the same.—M.I.C.E., Bath.



[56100.]—**Ox-hydrogen Lantern.**—If you will refer back to p. 15, you will there find a sketch of a bellows of oblong shape that is practically identical with the double gas-bags. The way they are made is to first get the three boards cut to size, and glued up the thickness, say ½in. Let the board for the partition through the centre be a piece of sound wood without a shake or knot of any size. And to make doubly sure, I should recommend glueing over one side a piece of calico, and well painting the calico when the glue is dry with black varnish or Brunswick black. Appearance being also an element, you will want to cut up some strips of wood ½in. by ⅜in. Having cut the mackintosh cloth to shape, and well payed the seam with rubber cement as well, commence to put together. And here the ½in. by ⅜in. strips come in. Glue the edges of the boards, and stitch the mackintosh cloth over them; then glue the outside and screw on the strips of wood, which then form a bead all round. Well rub in glue all round the joints, and when dry you will find, if you have done the work as stated, to be quite tight. Bring out the outlet for the one gas through the top board, and the one from the bottom chamber in a similar way. You will want two pieces the width of the bag, and say 2½in. by 1in. for the whole to stand on, and this allows the bottom pipe to be brought out easily enough. One set of weights on the top board gives the pressure equally on both gases. If not clear to you, I will explain any details at any time.—INVICTA.

[56104.]—**Gasoline Gas-Engine.**—There are so many minor matters involved that a sketch or two would not demonstrate all necessary. I will, therefore, refer the querist to the Blue Books of two patents—viz., No. 4,342 of 1875, and No. 1,933 of 1879. The first of these contains the simplest form of admission and exhaust valves possible, and is a thoroughly efficient one as well. The latter embodies the simplest form of firing arrangement in my opinion possible. The perusal of these two specifications will also give the querist information of a most valuable nature. And the two books can be bought for 6d. each. If you ask my opinion generally I should recommend a horizontal engine, not a vertical. As to sizes, I should, for the size you name, use a 6in. cylinder and 14in. stroke. As it is impossible for me to know what other particulars you require, I would suggest your embodying them in another query, and I will do all I can to help you.—INVICTA.

[56105.]—**Lever Fusee.**—I have often "scraped" out the turns of fusee by setting fusee in turns, and holding a properly-shaped cutter on rest, work the fusee towards you and press cutter to meet. It needs long practice to do it at all, and then it is only "scraped." I would advise "O. C. T." to send it to a watch jobber, where he will get it cut for 6d.—ANNIE.

[56106.]—**Gun-Barrel Browning.**—I think I omitted, in writing at first, to say that for twist barrels of all kinds the mixture should be put on very light; but especially in your case, where the figuring is delicate. My way is: A small quantity of mixture in a saucer, dip sponge in, then squeeze with fingers, so as to get nearly all the mixture back into the saucer, and have your sponge merely damped. Try again, and if you don't succeed, let me know, and I will give you one or two of Mr. Greener's recipes, which ("Greener on Gunnery") he says give good results. But the mixture I have given is really one of the (if not the) best. I note it is also in Mr. G.'s book, though I, and many others I presume, used it before I ever heard of the book. I must apologise to those readers of the "E. M." who are interested for my omission; but in any case it is most difficult, if not impossible, to convey to others in writing even the simplest process.—ARMOURER.

[56108.]—**Microscopic Staining.**—In addition to the address I gave last week, I might mention that aniline dyes may be obtained from Mr. Chas. Collins, 157, Great Portland-street, London, W., and from Mr. William West, 15, Horton-lane, Bradford.—G. L. M.

[56111.]—**A Legal Question.**—The board responsible for the maintenance of the roads in its district must keep these roads in repair, and the putting up of tressels in daylight to divert the traffic from a part needing repair to a part newly repaired is no obstruction. Generally speaking, without knowing more of the circumstances, I, as a lawyer, would not advise "G. C. C." to raise an action against the board in the event of an accident occurring to a carriage caused by the presence of the tressels.—B.Sc, Plymouth.

[56112.]—**Testing for Arsenic in Wall-Paper.**—The following, in answer to "J. K.," I should recommend as a test for As. A hydrogen bottle, fitted with a tube bent at right angles, and terminating in a jet, is supplied with zinc and dilute sulphuric acid, both of which should be free from arsenic. When the air has been all expelled, a light may be applied to the jet, the flame of which should not stain a surface of white porcelain brought in contact with it. This condition being fulfilled, the substance to be tested may be introduced into the hydrogen bottle, and after a short time the jet re-lighted and again tested with the white porcelain; if arsenic be present, a brilliant black metallic film will appear on the porcelain. If the delivery tube is heated to a red heat, the gas will be decomposed, and arsenic deposited as a metallic ring inside the tube behind the heated portion. This test—called Marsh's test—depends on the fact that nascent hydrogen combines with arsenic, forming therewith arseniuretted hydrogen. Should this explanation not be clear enough, I shall be happy to afford any further information.—J. KEAN.

[56118.]—**American Gas-Bags.**—See my reply more fully to "Oxygen's" query. I think the only new points you mention would be for one, the kind of cloth, or rather mackintosh. This should be a make having two or three layers of rubber between layers of linen cloth; and can be bought at any indiarubber warehouse of size. At the same shop you can buy the rubber cement for the lap-joint. The only other point, I think, is the size. For a dissolving lantern I should have the boards, say, 40in. by 30in., and the flexible sides of, say, 2ft. 3in., or 2ft. 4in. high. If any other points are not fully explained to your mind, I will reply to a query and make the same clear at any time.—INVICTA.

[56119.]—**Magnitude of Small Stars.**—From "Star Gazer's" reply, I fear my query has the fault of being misleading. What I want is a formula for ascertaining the light-grasping power of any given o.g. For example, to find the smallest star which a good 5in. o.g. ought to show: if there is such a formula, to whose magnitude scale does it apply—viz., Argelander, Sm. or H.?—H. A.

[56124.]—**L. B. and S. C. Engines.**—The following are all the dimensions I can give you of the "Terriers":—Cylinders, 15 by 20; six-coupled wheels, 3ft. 10in; weight on leaders, 8 tons 8 cwt.; on drivers, 8 tons 12 cwt.; on trailers, 8 tons 6 cwt.; total, 25 tons 6 cwt. All have the Westinghouse brake.—W. B. P.

[56124.]—**L. B. and S. C. Engines.**—The chief dimensions of the "Terriers" are:—Diameter of wheel, 3ft. 11½in.; cylinder, 13 × 20. Total wheel base, 12ft. Boiler: length, 7ft. 10in.; diameter, 3ft. 6in. Firebox (inside): length at bottom, 3ft. 5in.; at top, 3ft. 1in.; breadth at bottom, 2ft. 11in.; at top, 2ft. 9in.; height, 4ft. Firegrate area, 10·3sq. ft. 125 tubes, length, 8ft. 3¼in.; diameter outside, 1¾in. Heating surface tubes, 473; firebox, 55 sq. ft.; top of chimney from rails, 11ft. 3in.; weight in working order, 24 tons 12cwt.; capacity of tank, 500 gals.; bunker holds 10cwt. of coal. Description, and full dimensions, in *Engineer* for February 28, 1873.—B. LOCKHART.

[56126.]—**Chemical Examination, London University.**—If "Londoniensis," has not time to study for his matriculation exam., he had better postpone it. To my thinking, it is only an insult to the readers of "Ours" to ask them to assist him in "cramming."—B.Sc., Plymouth.

[56129.]—**Legal.**—(1) The money in bank in the joint names of A., B., and C. can be drawn by a majority, that is any two of the three. (2) B. is not actionable, and, consequently (3) incurs no punishment.—B.Sc., Plymouth.

[56134.]—**Taps and Dies.**—It is not practicable with a screw-plate, to cut threads that will fit without shake in holes cut by taps made from the same screw plate. A little pair of stocks and dies are what you want.—INVICTA.

[56135.]—**Value of Gas Liquor.**—Gas liquor of the usual strength—viz., 5 degrees Twaddel, contains 2·55 per cent. of ammonia, and it requires about 10½ tons, or, say, 2,300 gallons of liquor, at the above strength to make a ton of sulphate of ammonia. The present price is from 8s. to 9s. per ton (220 gallons).—STUD. INST. C.E.

[56135.]—**Gas.**—The liquor may be of any strength, to be found by using a hydrometer, known as Twaddel's. The process is very simple. For commerce it should not be less than 8oz. strength. 18lb. to 20lb. of sulphate are produced from a ton of cannel coal, or about 30gal. of liquor of 5 strength. One ton of liquor = 200gal. should yield about 1cwt. of sulphate, worth about £15 to £20 per ton. Liquor is worth now about 8d. per ounce strength per ton, that is at, say, 8° 8 × 8 = 64 = 5s. 4d.; but liquor is at present very cheap.—R. HANNEN, F.S.I.

[56136.]—**Composition of Gas-Lime.**—The following is an analysis of the above by the late Dr. Voelcker:—

*Composition of Gas-Lime (dried at* 212° *Fahr.).*

| | |
|---|---|
| Water of combination and a little organic matter | 7·24 |
| Oxides of iron and alumina, with traces of phosphoric acid | 2·40 |
| Sulphate of lime (gypsum) | 4·64 |
| Sulphite of lime | 15·19 |
| Carbonate of lime | 49 40 |
| Caustic lime | 18·23 |
| Magnesia and alkalies | 2 53 |
| Insoluble silicious matter | 0·28 |
| | 100·00 |

If the above is not what "Sulphur" requires, and he will advertise in the Address Column, I will try and assist him.—STUD. INST. C.E.

[56137.]—**Tracing Paper.**—"Jod" must be very hard to please if he cannot make a suitable tracing paper with Canada balsam and turpentine—using everything of the best. However, as he is not satisfied, let him try a solution of best beeswax in turpentine, brushing over both sides of the paper, and hanging the sheets up to dry for a few days, where they will be free from dust. Some use a solution of gum mastic in turpentine.—N. E. CHILD.

[56143.]—**Hermit Crabs.**—Hermit crabs usually feed on molluscs and most of the animal refuse of the seashore. Increase of size renders it necessary for hermit crabs to leave their old shells and seek new ones, and this may explain why yours creep out of their shells and die.—BOBADIL.

[56143.]—**Hermit Crabs.**—They are not very easy to keep. Keep them in a shallow basin with water constantly changed. I have generally found them eat small pieces of raw meat greedily; but they will not eat anything the first three or four days after they come from the sea. You will not manage to keep them in good health for many months.—R. A. R. BENNETT.

[56144.]—**Sea-Anemones.**—They are, I think, a variety of the Daisy Anemone (*Sagartia bellis*). You can find them out if you will refer to "A History of the British Sea-Anemones and Corals" ("Actinologia Britannica," by P. H. Gosse) under the head of "Daisy Anemones." As a general rule they live on the rocks, and not amongst the sand, &c. I have some in my aquarium which live in stones with a long hole in them, at the top of which the Daisy expands its disk. They are fine specimens if they are as much as 1½in. across.—R. A. R. BENNETT, Oxford.

[56146.]—**Spiral Springs.**—Yes, there is a special wire made for spiral springs in Bessemer; it should be about ·070 carbon in small sizes; but why not buy them?—you will find it the cheapest, and get a better spring. It is in the hardening where you get wrong. You will have to heat them regular, or you will not get a good spring. I should get a bit of flat iron, lay it in your fire, get it a good heat, then lay on your springs; lift iron and springs together, drop in oil. In tempering, get a bit of wire, put it through the springs, roll it about till tempered. If you cannot get them to stand your test write to me; I can supply you with them. See sixpenny sale column.—JAMES PARISH.

[56148.]—**The Thermal Unit in Relation to Time.**—This question is very like the style of Twisden's questions in theoretical mechanics, in that it contains about four queries under the disguise of one, but it does not resemble the said gentleman's questions in clearness. Take the case of carbon or sulphur, "Equivolt," and say exactly what you wish to know. At present I can only guess that you want some information about calorific powers and intensity.—WM. JOHN GREY, F.C.S., Analytical Chemist, Newcastle-on-Tyne.

[56150].—**Time Required.**—It would take a constant 12¼ft. head, or equivalent pressure, above 4ft. 2in. from top of the tank to fill it in 18 min., and the top portion of the tank would be filled in 6·84 min.—G. PINNINGTON.

[56150.]—**Time Required.**—Supposing, the 4in. supply-pipe is 100ft. long, and has a head of 5ft. It should then deliver $2356{\cdot}2 \times {\cdot}3333^2 \times$

$$\sqrt{\frac{{\cdot}3333 \times 5}{100 + 50 \times {\cdot}3333}} = 31 \text{ cubic feet per minute.}$$

The capacity of the receiver below the inlet pipe is 113 cubic feet. Then 113 ÷ 31 = 3¾ minutes required to fill this portion. The whole receiver contains 163 cubic feet, requiring 18 minutes in filling; then 18 − 3¾ = 14 minutes occupied in filling the upper 4ft. of the receiver, representing a space of 50 cubic feet. I think your receiver, under the conditions stated above, would fill in much less than 18 minutes. At any rate, you can oblige the "E. M." with the result of your experiment.—YAMA.

[56151.]—**Boring Lathe Heads.**—To "INVICTA."—I am sorry this has been overlooked by me, and tender my sincere apologies to "Uncas" for the delay. The way I should do it is as follows: First, file up and true the underside of the headstock so that it is perfectly true; this, then, gives us a base to work from. Now we must proceed next according to whether or not the castings are cored out for the spindle; if they are cast with a cored hole, it will increase our difficulties. And I will take the most difficult way as the illustration. We now fill up the hole or holes, if both ends are cast through, with a piece of the hardest wood we can find; and then, placing the headstock on the planed bed of the 2¼in. centre lathe with a scribing block we carefully find and locate the exact centre where the mandrel should run. Having marked this off on our wood plug, which should be smoothed off and well chalked to make our marks clear, we ascertain the external size of the bush in which the mandrel is to run. And having ascertained this, we strike off a circle on both sides, on the cast iron itself, and mark the circle by centre punch marks. A second circle, 1-16th or 3-32in. larger, again should be struck and centre-punched also. Now we must see what tools are available. We want a Morse twist drill, say ⅜in. diameter, and having marked off on the wood plug a ⅜in. circle, and another one a trifle larger, we fix the drill in the lathe and bore carefully through the wood plug. Previous to boring we, of course, very carefully set the work true and square on the lathe bed. Having got the first hole drilled, if we have done the work carefully, the drill will show by the larger circle that it has not run sideways at all, this being the use of the second circle. Now we bore the plug in the back centre in the same way. What we now want is a cutter bar, turned down in the front part to the exact size of the Morse drill—viz., ⅜in., and with a cutter 1-16th smaller than the finished hole, bore out the wood plug and the cast iron at the same time, the bar being carried in the wood plug in the back end of the casting serving as a guide. Next we must get either a rose-bit or a milling cutter, and, securing it to our cutter bar, take another cut through the already trued-up hole, taking it smoothly out to the full-finished size. We now bore the back centre, using the front-bored hole as a guide; and when this is got out to size our difficulties are over. Supposing the headstock is cast solid, the job is easier far, as then it means drilling a hole through both sides, so as to come exactly in the scribed lines; and the cast iron, of course, makes a far better guide bush for the bar than the hard wood plug. With care a first-rate job can be made in either way. I trust this will enable you to do what you desire.—INVICTA.

[56152.]—**Tempering Steel.**—What you should do is to first heat the tools up to a blood red, or a little more, according to the class and quality of the steel, then plunge vertically in water; you will now find (or should do) that you cannot file them. Next you temper them as follows: Brighten on the grindstone one or more faces of the tools, then hold them, if small, over a gas flame or over the coke fire, holding the thickest end next the heat, and you will see the colour come and change. You must then cool off quickly in water when the right colour shows. For turning tools for iron I use the tool dead hard or very nearly so, whilst for wood-cutting tools a full straw colour is right. You have apparently been trying to harden and temper at one operation; but this is not possible, unless you want the tools dead hard.—INVICTA.

[56155.]—**Dry Rot—Borer**—This query should not be headed "Dry Rot," as that has nothing to do with the holes bored in his furniture complained of by F. Search. They are made by insects of the genus *Ptinus*, the commonest of which in this country is the *Anobium striatum*. Benzole kills them, and cyanide of potassium is certain death to all the insect tribe; but very great care must be taken in its use, as it is one of the most virulent poisons we possess.—B.Sc., Plymouth.

[56156.]—**Chemical Action in a Chromate Cell.**—On being heated with strong sulphuric acid, potassic dichromate is decomposed with evolution of oxygen, thus—

$$\underset{295}{K_2Cr_2O_7} + \underset{392}{4H_2SO_4} = \underset{393}{Cr_2(SO_4)_3} + \underset{174}{K_2SO_4}$$
$$+ \underset{48}{3O} + \underset{72}{4H_2O} \qquad 687.$$

If the sulphuric acid be dilute and cold, there is a tendency to this reaction, which, however, does not actually occur unless some substance capable of taking up the liberated oxygen is also present. In the chromate cell the $SO_4$ of a molecule of acid combines with some zinc, forming $OZnSO_4$. The liberated hydrogen displaces the hydrogen of the next molecule, and the displaced hydrogen of that molecule turns out the hydrogen of the next one, and so on, until the carbon plate is reached. Here the hydrogen has no $H_2SO_4$ upon which to act; it therefore conspires with the acid to break up the chromate molecule, and we have the reaction—

$$\underset{295}{K_2Cr_2O_7} + \underset{392}{4H_2SO_4} + \underset{6}{3H_2} = \underset{393}{Cr_2(SO_4)_3}$$
$$+ \underset{174}{K_2SO_4} + \underset{126}{7H_2O} \qquad 693$$

The change is rendered evident by the gradual alteration of colour, from the orange red of chromium acting as an acid, to the dark purple of chromium acting as a base. The solution finally contains potassium chrome alum; but I do not think it would pay for recovery.—WM. JOHN GREY, F.C.S., Analytical Chemist, Newcastle-on-Tyne.

[56156.]—**Chemical Action in the Bichromate Battery.**—If querist can refer to p. 17, Vol. XXXVII., he will find an answer to his query. It appears that the zinc dissolves in the acid and liberates hydrogen, which reduces the potassium bichromate, thus:—$K_2Cr_2O_7 + 4H_2SO_4 + 3H_2 = K_2SO_4 + Cr_2(SO_4)_3 + 7H_2O$. Zinc sulphate, potassium sulphate, and chromium sulphate are thus formed, and the pot. and chrom. sulphates crystallise together with 24 molecules of water and form "chrome alum." The solution does not become black, but very dark green, which is the colour of the chromium sulphate formed. I don't think any practical use can be made of the used-up liquor unless the salts can be separated, which wouldn't be worth the trouble.—R. A. R. BENNETT.

[56163.]—**Mandrel.**—F. Shakespear has bent the nose of his lathe mandrel, showing that it is not hard-tempered, and he can bend it right again as I did mine last week, by the careful use of a hammer.—B.Sc., Plymouth.

[56167.]—**Developer.**—This is a very good developer, and not particularly "slow" if used correctly. You do not develop your plates long enough. You should go on not only till "the detail, &c., are fairly discernible," but till they have come out distinctly and then disappeared again. If the picture has come up very distinct, and then gradually lost itself in a kind of haze, when that plate has been through the fixing operation it will be a good one. From your saying they are "covered by a greyish mist," I should think you have a slight fog on your plates. Look out for a pinhole somewhere in your camera. Fry's plates are very good when properly managed; but I cannot help fancying that Marion's "Britannia" plates are easier for an amateur—at least, that is my experience. Try the sodic sulphite developer, and most likely all will come right. I do not see why a c.d.v. should take a shorter time than a cabinet if the developer is the same strength. If you do not succeed now, write again.—R. A. R. BENNETT.

[56167.]—**Developer for Dry Plates.**—"Jay Pea's" difficulty most likely arises from the fact of his diluted ammonia having lost its power. Remember what is called liquid ammonia is water holding the gas in solution. I was constantly troubled with the failure of developer to work properly till I gave up the common plan of mixing ammonia with a stock solution of developer. I commenced the plan of mixing the ammonia as wanted from a considerable bulk, and since then have found the developer work with much more regularity. I shall be glad to send "Jay Pea" the formula I use. A picture should, if properly exposed, be developed complete in five or six minutes. If you are a long time developing your picture, it will be little good. It will lack brilliance, and be slow printing.—A. PUMPHREY.

[56170.]—**Microscopical.**—It depends on the user. Myself I cannot see so clearly in a binocular as in a monocular. Try "Practical Microscopy," by G. Davis; "The Microscopist," by J. H. Withes; or "How to work with the Microscope," by Beale.—E. A. TINDALL.

[56170.]—**Microscopical.**—I should most strongly advise Mr. Barnett to use a single microscope for general work, and also for delicate work. A binocular is troublesome to work with, and is also very expensive. By a *single* microscope I do not mean a *simple* microscope; but a compound instrument with one tube. For beginners, I can recommend "Common Objects of the Microscope," by the Rev. J. G. Wood (Routledge and Sons), or "The Microscope," by the Hon. Mrs. Ward (Groombridge and Sons). A beginner might also read an article in the *Journal of Microscopy* for January, 1885, by Mr. Latham, on "The Microscope, and How to Use It."—Enal.

[56170.]—**Microscopical.**—H. T. Barnett is sure to get opposing opinions to his query. Microscopists may be divided into two schools—those who make microscopes, condensers, test plates, and diatoms their hobby, and who think that a month is well spent in resolving whether or not a diatom valve is sunk, or level with the surface: men of this school generally go in for binoculars. The other school are those who use the microscope as means to an end—namely, knowledge with a view to benefiting the human race, such are Pasteur, Virchow, Recklinghausen, Koch, Klein, &c., &c.: men of this school invariably use the single plain microscope; so do analysts, and also the large class of microscopists who use the instrument for trade purposes, such as brewers, calico printers, &c. I do not know of any better books in the English language than those of Carpenter or Beale; but if you can read French, you will find Ranvier's "Traitè Technique d'Histologie" very useful.—B.Sc., Plymouth.

[56171.]—**Gas-Engine.**—I would not advise a vertical engine at all. The horizontal, in my opinion, is far better. Clerk's engine is a horizontal, not vertical, one. I must, I think, draw your attention to the cost you will be involved in in patterns, &c., for making one engine, and I fear it would never pay you; in fact, commercially, it would be far cheaper to buy a second-hand engine than make one for yourself. If you decide to go on and do not mind the expense, I will do my best to help you; but you are entering on an expensive experiment. I wish to place the matter honestly before you now. If you proceed you cannot then blame me for involving you in a large outlay. Let me also know what horse-power, about, you want—not nominal, but actual. It is, of course, quite on the cards that an engine specially designed might not work perfectly satisfactorily, because other patentees would have to be kept clear of, and the way is now pretty well closed against any more successful new gas-engines without infringing previous patents.—Invicta.

[56175.] — **Books on Herbal Medicine.** — "W. M." will find Culpeper's as good as any; but as all the useful herbs now come from America, perhaps some one will tell him whether there are any books published there which will suit him. Let him read Lescher's "Elements of Pharmacy" and Squire's "Companion to the Pharmacopœia" —unless, indeed, he wants to set up as a "Herbalist." If that is his object, of course, "sorry I spoke."—N. E. Child.

[56177.]—**Earthenware.**—Try a slip composed of 4 parts of ordinary whiteware potter's ball clay and 1 part of dried ground flint under the glaze; if that presents any difficulties in the way of cracking or peeling, add a little plaster of Paris and sand.—Pottery Tech.

[56177.]—**Earthenware.**—In all the potteries I am acquainted with white clay is used for producing white earthenware, and the idea of colouring earthenware white would be treated as a joke.—B.Sc., Plymouth.

[56179.]—**Bort.**—In answer to "Carbon," I would say that "Carbon" ought to know more than I do as to the nature of bort and carbonado, seeing that carbon is the base of each. Bort is diamond gem splinters, or impure diamond; carbonado is the same material as diamond, but not crystallised. Save for, or by reason of, difficult processes, which some even doubt to this day, neither diamond gem nor bort (impure diamond) nor carbonado can be manufactured. I should say that both are Nature's products, and, practically speaking, cannot be manufactured.—Z. Y. X.

[56183.]—**Force and Motion.**—The rope with a horse pulling at each end will be strained equal to the pull of the strongest of the two horses only. With a piece of cord suspend, say, 1cwt. to a Salter's spring balance attached to a nail in the wall. The spring will represent one of the horses, the weight the other horse; the index fingers will point to 112lb., and this is the strain on the cord, spring, and the nail. Respecting steam-engines, the pressures on the piston and its cylinder cover are in equilibrium under all conditions.—Yama.

[56183.]—**Force and Motion.**—Suppose one end of the rope was fastened to a wall, and a horse pulled at the other with a force of 120lb., clearly the strain on the rope would be 120lb. If the reaction of the wall is replaced by a horse pulling at the other end with a force of the same magnitude, the effect on the rope will not be varied. Similar reasoning applies to the case of the piston and cylinder cover.—Wm. John Grey, F.C.S., Analytical Chemist, Newcastle-on-Tyne.

[56185.]—**Astro. O.G's.**—In oblique refraction light is separated into colours. Any small portion of a convex lens is a prism, so that the focussed rays are seen to have the prismatic colours, and, therefore, an image is fringed with these colours, and is also indistinct, as they are not focussed at a point; but the degree in which this takes place is independent of the focal length of the lens, and so long as the aperture is the same, the degree of colour is the same. Hence, by increasing the focal length, the edge of colour remains the same, while the image is magnified by a given eyepiece in proportion. And so the edge of colour may be reduced to a minimum, and be practically made invisible by increasing the focal length. Hall, in 1729, conceived the idea of an achromatic lens; Dollond, in 1758, brought it to perfection. This principle enabled the opticians to dispense with the great length of their telescopes. Compare a modern telescope with the 150ft. one of Hevelius's, and the old method of correction for chromatism is obvious. I do not know off-hand what size telescope Cassini used; but I venture to think this explanation will account for the object of your wonder.—E. A. Tindall.

[56186.]—**Gum for Micro. Slides.**—What is the querist's difficulty? Do the labels came off the glass again after being fastened on with the gum he uses? If so, use a gum made of gum arabic ½oz., powdered gum tragacanth ½oz., water 1½oz., acetic acid 20 drops, and they will come off no more. —R. A. R. Bennett.

[56196.]—**Gas Holder.**—Tape soaked in a mixture of boiled oil and red lead laid along the joint, and the plates riveted, is the material used now, I believe, by the principal gas-holder makers. If not to be used at once, it is better to soak in boiled oil alone, as the red lead cracks if allowed to dry. —Stud. Inst. C.E.

[56196.]—**Gas Holder.**—Tape, saturated with red lead and oil, is now generally used in the best class of work. Ordinary string was formerly used, and is now sometimes; but the tape makes the best and soundest joint.—W. M.

[56200.]—**Diamond Carat.**—The word "carat" is derived from the name of a plant, the seeds of which were used for weights. It is 3·17 grains, or ·2054 grams.—Wm. John Grey, F.C.S., Analytical Chemist, Newcastle-on-Tyne.

[56200.]—**What is a Diamond Carat?**—151½ English carats go to 1oz.—i.e., 480gr., so one carat = 3·17gr. The French carat is 3·8gr., United States 3·2gr., Dutch 3·0gr. Mr. Emanuel no doubt means "pearl grains," 600 of which go to the oz. —R. P. G.

[56201.]—**Fixing Battery Plates.**—As far as I understand your description, the battery is the shape usually employed. If so, why not use the brass screw clamps, which are made on purpose for fixing the zincs to the board, and can be obtained from any electrical dealer, such as Dale, 26, Ludgate-hill, E.C.?—R. A. R. Bennett.

[56203.]—**Chemical Affinity.**—It is quite impossible to deal with this subject within the limits of a reply; but if the Editor approves, I will send an article next month.—Wm. John Grey, F.C.S., Analytical Chemist, Newcastle-on-Tyne.

# UNANSWERED QUERIES.

*The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered are repeated four weeks afterwards. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.*

# QUERIES.

[56207.]—**Clock Repairing.**—I have an eight-day clock which stops: the clockmakers tell me it is worn out. I have looked at it, and the train seems all right, and the holes and pivots as well; the only thing I can see is the face of the pallets seem a little worn. Can any reader suggest anything I can do to make it go? I can see no reason why it should stop. I have looked through back numbers of the "E.M." and see nothing on clock mending, so perhaps a few hints may be useful to others as well as myself.—A Many Years' Subscriber.

[56208.]—**Train Indicator.**—While waiting at a suburban railway station one day, I noticed in the ticket collector's box, which was below the platform, and so placed that he had no view of the platform; an indicator with a dial marked train in on one side, and train out on the other, and a pointer moved from one to the other, according as the train went in, or went out of the station. Could any brother reader tell me how this apparatus works?—Mikros.

[56209.]—**Sunshine Recorder.**—I have seen somewhere a description of a sunshine recorder, invented, I think, by Capt. Abney. I should very much like to make one if it is not patented, and would be obliged to any fellow reader who could give instructions for making and using it. It consists of a box with a curved bottom, on which rests a piece of sensitised paper, on which the sun, shinning through a hole in the lid, traces a black line, but beyond this I know nothing about it.—Mikros.

[56210.]—**Electro-Plating.**—Will any reader inform me how to prevent the crystals forming on the cathode? I have added silver to the solution and fresh cyanide, but without effect. The crystals form on all the edges of the work, and at times some streaks of brown are seen on the work?—One in Trouble.

[56211.]—**Water Pressure.**—Will any reader give a simple rule for finding the height an ordinary fire-hose jet will throw, with a given pressure, at the same level as the jet?—Engineer.

[56212.]—**Dr. Johnson's Opinion of Mechanics.** In his Dictionary he describes a mechanic as a "low person." Can you tell me whether mechanics of the time of Dr. J. were low, according to the present derogatory signification of that term, or does the Doctor mean they were merely persons in a humble or lowly position in society?—C. H.

[56213.]—**Common Red Ware.**—To S. Ablidge. —Will you kindly oblige with the following information about common red ware? Percentage composition of red clay suitable for this ware; mesh of lawn used to sift the slip; is the clay made on a slip kiln? Are the large jowls thrown on the wheel or moulded? Are glossed goods in this class of pottery fired biscuit first, or only one fire? Are seggars used? What is usually time of firing and temperatnre at maximum for biscuit and for gloss?—Pottery Tech.

[56214.]—**Christofle.**—Could anyone tell me what is the composition of a compound metal called christcfle, and often used for imitating silver for spoons and folks, and also the proportion of silver it contains?—Wade.

[56215.]—**Nickel.**—Is it possible to deposit nickel on glass, in the same way as silver? If not, could a film of nickel be deposited on the silver film? — C. L. Tweedale.

[56216.]—**L. and S. W. Express Engines.**— According to the number and dimensions of the tubes in these engines, as given by "Meteor" in English Mechanic of 13th inst., I calculate the heating surface to be 1,001·3 square feet, and not 1,051·13 square feet as quoted by "Meteor." Will "Meteor" (letter 23944) kindly say how this discrepancy comes about?—E. M.

[56217.]—**Solar Eclipses.**—To Mr. Pearson.—I should be glad to learn your interesting method of computing eclipses, but I cannot understand all the steps of your calculation. Will you kindly show me how to find geoc. lat. and long., and also how the diagram is constructed, and what is meant by diff. of decl. and X cos. D? I am likewise puzzled with the last two steps in Element II. You see I want a good deel of instruction, more perhaps than you will find it convenient to give me. —Mx.

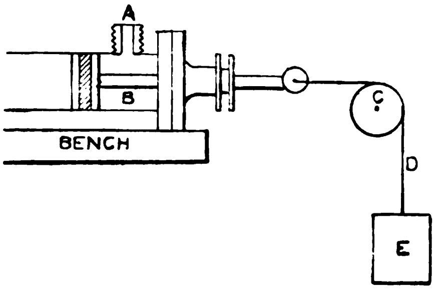
[56218.]—**Electric Clock Dials.**—I want to make a double-dialled drum, size of dials 30in., to be driven by electricity from an ordinary Graham regulator. Wanted to know—best driving action to prevent derangement of hands by wind or other external force, description and size of magnet, what battery, size and number of cells, how often to close circuit, what wheel of regulator to make contact, description of contacts; are platinum contacts necessary or desirable?—A Barbarian.

[56219.]—**Edges of Old Violin Belly Splintering.**—Could any correspondent suggest a kind of varnish or polish that would lie on and adhere, so as to prevent a silk handkerchief being caught by a splinter on the edge of the belly, when rubbing the violin over after use? The splinters are caused by old age, seasoning of the wood, and by wear and tear.—Bumstaal.

[56220.]—**Medical Coil.**—I have bought a coil much out of repair. Both primary and secondary have been taken off; on base board is a little three-way switch arrangement, the lever can be turned on to any of the three studs, but all trace of connections gone; other work all complete. Will some reader tell me how to arrange the secondary with the switch, as I suppose it has been so?—Electric

[56221.]—**Blue Shadow.**—In July, 1883, while travelling on the Rideau Canal, in Canada, the sun being so obscured by haze as to present a coppery appearance, I noticed that the shadows cast on the book I was reading were of a greenish-blue colour—about turquoise blue. The same was noticed by other passengers, so that it was not an optical illusion. Travelling on the railway every evening just after sunset, with a gaslight overhead and light also entering the car windows from the west, the same phenomenon occurs—the shadows of objects held between the gaslight and my newspaper being a decided blue. This disappears when passing through a tunnel, and also gradually diminishes as darkness approaches. I would be pleased to have an explanation.—J. Gayler.

[56222.]—**Testing Pressure Gauges, Safety-Valves, &c.**—Would some correspondent kindly tell me if I am right in the following? The cylinder in sketch is 1in. bore; the boss A on top of the cylinder is to connect to safety valves, &c., to be tested. Now suppose water were forced into the cylinder at B by a force-pump until the piston and rod were forced down, and the weight E lifted by means of the cord D running over the pulley C. Supposing the weight E was exactly 20lb., am I right in supposing the pressure in the cylinder B would be 20lb. on the circular inch, and, of course, on the gauge or safety-valve that was being tested? In the case of a safety-valve the weight might be moved along the lever just till the valve blew off; the lever might then be marked 20lb. at the place where the weight was hanging. I am aware there would be the friction of the piston and the rod, but if the apparatus was well made, that would be very slight—I should think scarcely worth taking into account. If the cylinder B was bored out 1 3-16in., would that make it equivalent to a square inch? An answer to the above questions would oblige—Jack.



[56223.]—**Grinding and Polishing Plate Glass.**—I wish to grind and polish some pieces of plate glass, 6in. by 6in. Should feel obliged if some one would describe the machines used for the purpose; I wish to work them very true.—W. J. B.

[56224.]—**Dynamo.**—To Mr. Bottone and Others.—I want to make a small dynamo to be worked by a 4 man power engine, to light 6 10-c.p. 10 volt incandescent lamps. Will you kindly give me size and weight of wire for armature and field magnets, and oblige—A Constant Reader.

[56225.]—**Spray.**—Requiring to convert a liquid colour into spray, I made an apparatus like this: Two tubes soldered on opposite sides of a tin plate, the top one having nicks in its circumference so as to send jets of air at right angles to a ring of small holes in the plate communicating with the lower tubes, so that the air jets cut across the water jets. But I found that the thing would not act; the water, so far from rising in the tubes, was depressed, and not a particle of spray produced. Why was this?—it ought to have acted.—S. R. Preece.

[56226.]—**Frame Gilding.**—Can any of our correspondents put me in the way to obtain a knowledge of gilding and burnishing for picture frames, called water gilding—this to distinguish it, I believe, from gilding in oils? Please say how frames are prepared in the white, and also frames for regilding? Is there any work published on the subject?—C. C. B.

[56227.]—**Vacuum.**—Could any of your kind readers tell me the best practical means to obtain a nearly perfect vacuum in a vessel, say 1 cubic foot? What would be the pressure outside per square inch? Also, can a vacuum be made at the front of a rigid plate so as to hold another one in front of it which will have to stand a friction of 5lb. per square inch, and if india-rubber could be used as packing between the two plates; if not, what is the best material for packing, or to make a perfect joint between the two plates?—One Who Wants to Know.

[56228.]—**Storage Batteries**—Will some kind reader of "ours" very kindly give directions for making a good simple storage battery, suitable for fairy lamps, that could be charged by six good sized granule cells? An answer to this would greatly oblige—Lux.

[56229.]—**Cholera Bacillus.**—Can any reader of "ours" shortly state, what is the scientific aspect regarding the nature of the above, at the present moment?—F. D.

[56230.]—**Submarine Light.**—Having heard that such lights are in use on the Norwegian coast, for the purpose of attracting the fish, if any of your numerous correspondents could advise me where they can be had, together with directions for use, they will confer a great benefit on fishermen? The electric light could be utilised, but is too costly and cumbrous.—Trawler.

[56231.]—**Dynamo**—To "W. H. E." and others.—I have a small Brush dynamo, A. 11in. diameter, known as a 2,000 c.p. machine, 1,200 rev., 1½ h.p., gives about 10 ampères, 60 volts. It is too small now for my use; 3 arc lamps. I should prefer to have it arranged to give from 4 to 6 volts' for experiments in electro-metallurgy. How would this do? Rewind 4 coils with 6yd. 16 wire and connect to one set of brushes for external work; the other four coils to be used with remaining set of brushes for F. M. only, to be run at 1,600?—Posel.

[56232.]—**Photographing Sunspots.**—I have made a 9in. mirror of 10ft. 9in. focus for the above purpose, and succeeded in taking several fair negatives, showing number and position of spots; but in printing on the usual sensitised paper, unless printed very deep, the delicate spots disappear during toning and fixing. Is there anything better than paper for the purpose? Can any of our astro-photo readers help?—The Optical Bricklayer.

[56233.]—**Intensity Coil.**—I am making an intensity coil, the core of which is 6in. long. I have wound with two layers of No. 16 c.c. wire for primary, and have half a pound of No. 36 s.c. wire for secondary. How many square feet of tinfoil should be used in condenser? What battery power should be used, and what length of spark may I expect?—E. H. J.

[56234.]—**Wimshurst Machine.**—A great deal has been said in "Ours" about the Wimshurst machine, its construction and the length of sparks it is capable of emitting; but nothing (at least nothing has ever caught my eye) concerning its application to the sciences. 1. I would like to know, for instance, to what extent a set of 18in. plates would be applicable to the illumination of vacuum tubes, Crookes' tubes, Plucker tubes; and whether the current generated is strong enough to vapourise metals between carbon points for spectroscopic purposes; and, in a general way, what can be done with the machine in an experimental way? 2. Should the plates be ground on the periphery, and does the efficiency of the machine in any way depend on the thickness of the glass discs; if so, what thickness corresponds to the maximum effect?—Spectrum.

[56235.]—**Medals.**—I have a silver medal. On one side there is Jesus Christ asleep in the boat and some men trying to awake him, and around it is the following inscription; Intempestate Securitas. On the other side there is St. George and the Dragon, with these words: S. Georgivs Eqvitvm Patronvs. Would any reader give me any information respecting the above?—Penwith.

[56236.]—**Boring Mill.**—To "Invicta."—Many thanks to "Invicta" for his prompt answer. What I want at present is simply an idea of your smaller machine to be driven by hand, and bolted on to the front or flange of cylinder. Is boring bar, a screw, or is the head keyed on to it? Also, I want to know how feed is applied to head (with cutters on boring bar) as the head has to travel the whole length of cylinder? Do they generally put in three cutters on head, and do all three cut at once? No. 1 to take first or roughing cut, and No. 3 the finishing cut. An early answer, with sketch, if possible, will be most acceptable to—Hombre.

[56237.]—**Cylinder.**—I have a slide-valve cylinder, 3½in. bore by 6½in. stroke. Will any reader kindly give me a section of slide valve for it, showing lap and lead of valve? The widths of ports are as follows: Steam ports, ¼in. by ⅜in.; exhaust, ½in. by ⅝in.; metal between steam ports and exhaust, 3-16in. Also, what power will it be? Any advice, concerning setting of eccentric of same, will be thankfully received.—J. Gibson.

[56238.]—**New Steam Motor.**—Will "Invicta" kindly send full particulars of his new low-pressure steam motor, with sketch and dimensions, if possible? It seems to be just what I have been looking for—a safe motor up to about ½ horse power.—Safe Steam.

[56239.]—**Filtering Acids.**—Can any reader kindly inform me, what is the best and cheapest media for filtering an acid solution through, in quantities say, of 50 gallons per 24 hours? I have tried sand on the top of cotton wool, but this soon gets filled with precipitate. It is the filtrate I am anxious to obtain, the precipitate is useless.—F. G. S.

[56240.]—**Tug.**—I have a boat 5ft. 6in. over all, 10in. inside greatest beam, and 7½in. deep from floor to deck. I wish to fit it up as a tug. What is the most powerful boiler and engine I can put in her? I am going to make them myself. Would it be well to have cog wheels on the shaft to get a greater speed? I want it for racing with other models—she has fine lines.—F. C. S.

[56241.]—**Lenses.**—To Mr. Nelson.—Perhaps our kind friend, Mr. Nelson, would tell us the size and focus of those two lenses, and their distance apart, which he recommends for making his simple and most excellent condenser (see letter 23938, page 34). Would not a disc of blue glass be an improvement, and ring stops such as are in Swift's and other expensive condensers?—E. B. F.

[56242.]—**Dynamos.**—I want some information as to the method of calculating the E.M.F. of dynamos, from their dimensions and speed of rotation?—Wm. John Grey, F.S.I., Analytical Chemist, Newcastle-on-Tyne.

[56243.]—**Fuses for Projectiles.**—To "Garrison Gunner."—Will "Garrison Gunner" kindly state what fuses are now in use in the service? In connection with the deplorable accident at Shoeburyness, we read of "base" percussion fuses, "with delayed action," to me entire novelties. When I was in the R. A., a few years ago, the fuses we used were the G. S. Pettman, and the Boxer wooden time-fuses for M. L. and B.L.R.O.; also the "E" time, and the "C" percussion for the Armstrong B. L. guns. Are these fuses still in use, and did they ever succeed in making a "concussion" fuse that they used formerly to be so hopeful about?—Ex-Garrison Gunner.

[56244.]—**Skrivanov Battery.**—Will some kind reader tell me how to construct the above battery, and the cost of making and recharging it? I suppose the chloride of silver is the most expensive part.—Accumulator.

[56245.]—**Britannia Company's Foot-Power Circular Saw.**—On page 26 it is stated that a foot-power machine will, from the impetus given to it by the foot, cut 3ft. 8in. of mahogany 1in. thick, after the power (foot of a man) has been withdrawn. Will anyone come forward and say that they have actually seen the facts stated in the above statement? It seems to me so extraordinary that I ask the question. From the drawing the saw only makes, say, fifteen revolutions for each tread, or is the perspective bad?—Z. Y. X.

[56246.]—**Legal.**—B. is in a certain business, and takes a partner, C. B. has a house, used as a private residence, and also as a place of business. He sublets this house to C., taking another house himself, both houses being taken on a lease for several years to suit the partnership. After a few months B. represents to C., that if they dissolve partnership, a much more lucrative business can be taken up by B, who promises to employ C., and take all expenses and risks caused by the change, representing that the house leases are at a premium. The business partnership being cancelled, and B. being unable to pay the rental of C.'s house (the house now being empty and unlet) how should C. proceed? If the landlord takes possession of the house, is the lease thereby cancelled? If C. is unable now to pay anything, but engages in another prosperous business, can the landlord leave the house empty and sue C. for the whole amount of rent due? How should C. proceed to save present expenses and further liabilities? The house is a London one, let on the ordinary seven, fourteen, or twenty-one years lease.—W. H. B.

[56247.]—**Photographing Engravings and Plans.**—To Mr. Lancaster and Others.—With a lens averaging one second exposure for landscaping in sunlight, what would be probable exposure for taking a negative of above? How should the engraving be placed, and should there be any variation of developer to that usual in gelatine plates? I cannot succeed after many attempts.—M. E. N.

[56248.]—**Turning Cast-Iron.**—Will any fellow reader kindly inform me the best sort of tool to use, to take the hard crust off a new lathe-cône, as I want to turn and groove it. Having not turned any before, it seems to take the edge off every tool I use?—Jim.

[56249.]—**Electric Bell.**—I wish to make a single-stroke bell, armature suspended on pivots as in general use for mining gongs, diameter of bell to be 8in., No. of cells, eight Fullers; distance over which it will have to work, 200yds. Give size of cores, quantity and gauge of wire; also as above, but for a 10in. bell, to work over 2,000yds. with 10 Fullers.—Glam.

[56250.]—**Engine Making at Home.**—Referring to page 532, Vol. XL., on Engine Making at Home, would it do for me to make every part half the size, as I find 3ft. too large? And let me know if the bedplate would do if I got it made of mahogany or boxwood, as I think a metal one is rather expensive.—Snooks.

[56251.]—**Australian Vertebrates.**—Would some reader kindly tell me if there is any work published in the British Isles on Australian Vertebrates, or is there any book on Marsupials or Australian Mammals?—Enal.

[56252.]—**Latch Opener.**—Does anybody know whether there is any patent electrical door latch opener, such that it only requires a small battery power (two or three Leclanché) and that when once opened, it may stay open, till a person comes in and shuts the door?—J. K. S.

[56253.]—**Alizarine Oil.**—Used for calico prints. I would like very well to know what would be the best thing to put into this oil for padding the prints before steaming, to improve the red and clear up the white. I believe crystals of tin is a good thing, but does not work well.—A. C. M.

[56254.]—**Netting Square Mesh.**—How can I net so as to produce square mesh?—Anxious.

[56255.]—**Arranging Engine Belting.**—I want to drive a vertical pugmill from a horizontal engine shaft. The diameter of pulley on engine is 1ft. 6in., on pugmill 3ft., with flange on lower side. What should be the distance between the two shafts, and what elevation should the engine pulley have with respect to that of the mill? In what direction should the strap run?—T. M. D.

[56256.]—**Valve Gear.**—Would some of our readers kindly explain the valve gear of a gas-engine? I am anxious to make a model, but am not quite clear about the arrangement of the valve?—A Recent Subscriber.

[56257.]—**Telescope Stand.**—Will someone kindly tell me how I can best make a steady wooden stand for a small refracting telescope, which is about 39in. long, and 2in. diameter? I want the telescope to have altitude and azimuth movements. Please give dimensions, with small sketch if possible.—Omega.

[56258.]—**Reflecting Galvanometer.**—Will someone kindly oblige me with the following details in the construction of a Sir W. Thomson's reflecting galvanometer:—1. Size of coils? 2. Best material for the reels? 3. Amount of wire for each coil? 4. Size of wire? 5. Any peculiarity in winding, insulation, &c.?—Joh.

[56259.]—**Skrivanoff's Dry Battery.**—On page 119, No. 1019, "Starlight" described this battery. I have a small incandescent lamp marked (3·1) which, I presume, means volts, to be used as a scarf pin. Will "Starlight" kindly give dimensions for making one of these batteries that would light the above lamp?—Penwith.

[56260.]—**Wicker.**—A receipt for making a coarse black dye, suitable for basket work before painting; cheapness and quick drying essential, will oblige.—Wicker.

[56261.]—**Selenite.**—I have been recommended to use selenite for hardening my water for brewing purposes. Can any of your readers inform me, what it is chemically composed of, and how many degrees of hardness it would add to my water, if used at the rate of 2lb. for every 25 barrels?—F. E.

[56262.]—**L. and N. W. Tank Engines.**—Why are Webb's double-ended 8-wheeled passenger tanks constantly being turned on the turntable like tender engines? Are not tenders dispensed with partly to avoid turning?—W. B. P.

[56263.]—**G. W. Compound Engine.**—Wanted some particulars of a compound engine, said to have been lately placed on this line? What trains is it running?—W. B. P.

[56264.]—**Mechanics.**—Will any reader kindly solve the following question? Find the horse-power of an engine which will maintain a speed of 20 miles an hour with a train weighing 50 tons, the friction being 10lb. to the ton?—Alpha.

[56265.]—**Lalande-Chaperon Battery.**—To Mr. John E. Chaster.—will you kindly give the particulars of the above? How many cells would be required to light a 20 c.p. lamp? Kindly give the dimensions also.—A Young Electrician.

[56266.]—**Problem—Rolled Iron Joist.**—Will some engineering student oblige?—What safe load, uniformly distributed, will a rolled iron joist, resting on columns, carry, of the following dimensions—viz., 10in. by 4½in., mean thickness, ⅜in.; length of bearing, 15ft.?—Vita.

---

It has been found that 17,000 stops are made on the Brighton Railway per twenty-four hours, only about 10,000 of which are regular station stops.

## ANSWERS TO CORRESPONDENTS.

◆

*\.* *All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, 332, *Strand, W.C.*

### HINTS TO CORRESPONDENTS.

**1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.**

***\.* Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.**

### GOOD FRIDAY.

THE next number of the ENGLISH MECHANIC will have to go to press some hours earlier in consequence of Good Friday. All advertisements for the next issue must reach the office not later than 5 p.m. on TUESDAY next.

---

The following are the initials, &c., of letters to hand up to Wednesday evening, March 25, and unacknowledged elsewhere:—

BATES, HENDY, AND CO.—Pall Mall Electrical Association.—J. Wood.—J. O. White.—Armourer.—J. A. C.—Silex S-adrift.—Student.—Rev. Geo. Bishop.—Arthur Mee.—J. J. Hammond.—C. J. R.—Porcelain.—M. A.—S. Arlidge.—Antares.—$H_2S$.—W. G. P.—E. B. F.—A London Undergraduate.—Valetta.—Jno. M.—S. E. Hunt.—Adams.—J. H.—Invicta.—Annie.

MILLER. (It is doubtful whether a work giving the information you require has been written; but if you send a stamped envelope to the publisher of the *Miller*, Mark-lane, London, E.C., he will forward a list of books which he keeps on sale at his office.)—MILLER, Sowerby Bridge. (We are under the impression that certain books are recommended in the Syllabus; but see previous answer.)—W. E. SMITH. (You would prefer "being answered by post," would you? Well, we do not answer by post, nor reply to such questions as yours, as you will see on referring to Hints Nos. 4 and 5. You will find a description of the battery named by searching the indices.)—BOMBSHELL. (By means of the theodolite, or a small telescope rigged on a stand with an indicating plate.)—B. (Yes, diamonds have been produced artificially by crystallising carbon under the influence of heat and pressure. See pp. 2, 461, Vol. XXX., Nos. 781, 800, for an account of the experiments of Mr. J. B. Hannay, of Glasgow.)—R. V. (The figure of Britannia means the English mark for silver of 11oz. 10dwt. If the "lion's head" is a leopard's head, it is the mark of the London Company, or if it is the "lion's head erased" then the article is of London make, and the metal is standard silver, and cannot be of earlier date than 8 William III. Consult Gee's "Hallmarking of Jewellery," published by Lockwood and Co.)—M. (Fixateur, bandoline, or eau collante consists of any of the vegetable mucilages with a little spirit and perfume. A quarter of an ounce of carrageen moss will make three-quarters of a pint; but if wanted to keep, add one-third of its volume of Eau de Cologne. Quince seed, gum-arabic or tragacanth, malt, and other substances yielding mucilage are used and perfumed in any suitable manner.)—M. P. (Get some white lead and mix with equal parts of turpentine and boiled oil, adding one pound of dryers to every 8lb. of white lead. You can buy the white lead already ground in oil.)—J. W. (The number sent you must have contained something about the subject. There is a diagram in last week's issue which will show you how the wires are arranged, and there is also the index, by the aid of which you can refer to descriptions which will suit you. The primary wire is connected to the secondary, which is smaller, and you can continue adding coils of finer wire, bringing out ends at each junction, so as to get different degrees of power.)—A RECENT SUBSCRIBER. (For so-called automatic or self-acting fountains, see Nos. 459, 582, 801, 967, 973, 974.)—A STUDENT. (Why not procure the Calendar? No limit to age; but how long it takes depends on ability—three years, say. See the indices of back volumes.)—A. C. K. (See p. 476, last volume, and the indices generally.)—J. E. W., Adelaide. (Forney's "Catechism of the Locomotive," published at the *Railroad Gazette* office, 73, Broadway, New York, will suit you, though, of course, it gives only American examples. Dempsey's "Locomotive Engine," published in the "Weale's Series," you will no doubt find at the booksellers in your city.)—OILINE. (See the article on butterine in No. 1030, and look through the indices generally under that head and oleomargarine.)—SUSSEX. (For the manufacture of emery-wheels, see p. 297, No. 845; but perhaps you will find something in this number to suit.)—PAGET. (Directions for making the Wimshurst Influence Machine were given with illustrations on p. 242, last volume. See also the index of Vol. XXXVI., and many replies since that was published. Full as your description is, it does not give any indication of the electrical conditions, for you do not even show the position of the "brushes"—they must touch exactly opposite sectors. The discs should be as close as possible, and should be varnished before the sectors are attached.)—SUPERSTITIOUS. (Why not ask some of the ladies, or the jewellers who sell the rings? They have nothing to do with magnetism.)—W. W. (Indiarubber dissolved in bisulphide of carbon; but for sticking to the tires most people use such cements as Prout's glue, or the special preparations sold by the dealers in cycling requisites.)—A. BROWN. (Why should it corrode? Is it corroded now? The best way will be to keep it thoroughly clean, and dry out carefully after using it.)—SCHWARTZ. (If you will say what is to be understood by "tinning," we may be able to help you. If you mean coating metals with tin, we do not think you will find a "practical treatise," but there are articles in the cyclopædias and in the back volumes.)—J. W. A. (Most likely it was not received. You do not give any idea of what sort of information you require. The details of construction would be found in the technical papers about the time of its completion; but we know of no book giving the "necessary information up to date.")—J. B. (Indiarubber can be dissolved in bisulphide of carbon.)—TINMAN. (The blades of the fan should have very little clearance, and run towards the outlet. It is impossible to say what is the matter from your sketch and description. Perhaps you expected too much.)—G. R. K. (See p. 474, No. 931; but do you think violet would be so extensively used if it were possible to make a black equally as good?)—SCOT. (A calorie is the French thermal unit—the quantity of heat required to raise one kilogramme of water one degree of the centigrade thermometer; it is equivalent to 22 British thermal units.)—JAS. DOUGLAS. (If you procure the catalogue issued by Mr. Fletcher, Museum-street, Warrington, you will see illustrations of the burners and stoves required.)—BOTANIST. (Cyclosis is a term used to denote the circulation within the cells of vegetable tissues. It is best observed, perhaps, in the leaf of Vallisneria spiralis, but can be viewed in Anacharis, Chara, Nitella, or in the common Frog-bit—all aquatic plants.)—JAMES SHAW. (See the articles on photo-mechanical printing processes, pp. 173, 194, 215, 236, last volume; p. 580, No. 961, and the indices generally.)—S. C. S. (Indiarubber stamp-making described in No. 836, p. 94. It has been frequently explained that they cannot be made without apparatus.)—E. M. L. (Egg albumen—see p. 338 last volume, and the indices, for several recipes have been given.)—W. K. (We have heard of it before. If you believe that a few skeins of black silk cured you of lumbago, we have no wish to disturb your belief. Six months seems a long time for so remarkable an "electric belt." We are unable to find the "query.")—ANXIOUS. (Carbon tracing-paper is made by melting together 6 parts of lard and 1 of beeswax, and, as the mixture cools, stirring in sufficient lampblack to give the desired colour. Apply to paper whilst still warm, using as little as possible of the mixture to obtain a good coat.)—H. HARRIS (The question has been recently answered. See p. 547 last volume, and p. 66 last week. You must pay the company a royalty for being allowed to use the instruments, and arrange with the local authorities as to the erection of the wires.)—ANXIOUS, E.B. (We do not know whether it is possible to get rid of "tubicles on the lungs." You had better consult a medical man.)—C. HENRY. (Mercator was a Danish geographer. His maps are laid down on the assumption that the earth is a plane, and have special advantages for sailors. They have straight lines to indicate latitudes and longitudes. See any cyclopædia.)—J. W. A. (You do not appreciate the position. The query is of no interest to anyone but yourself, and the answer must be a gratuitous advertisement. Any large bookseller can help you. See p. 128, No. 551, and Vol. lvi. of the Proceedings of the Institution of Civil Engineers.)—STEAM BOILER. (You can find many recipes in back volumes; but we are afraid you want too much, for such a preparation would be worth patenting. You can keep a good deal of the scale off by filtering and softening the water before pumping into the boiler. Common soda will serve your purpose as well as anything.)—NIX. (Similar queries have been inserted. There is nothing better than plaster of Paris, which will yield as fine an impression as possible, if sufficient pressure is used.)—SELF HELP. (Stoves of the kind can be seen at most ironmongers, and can be bought much cheaper than they can be made.)—W. S. (Merely discs attached to the arbors that would otherwise carry hands. 2. Weale's Series is published by Lockwood and Co., Stationers' Hall-court, E.C. Why should we give the addresses of booksellers who allow a discount?)—MEDIOUS. (Silicated carbon blocks.)—GEO. WHEELER. (No, you must burn and scrape the tar off. 2. If you look under "Terms of Subscription," you will see that the publisher does sell cases for binding, price 1s. 6d. each. It is advisable to order through a bookseller, giving him the numbers of the volumes required.)—T. B. (Messrs. Lockwood and Co., Stationers' Hall-court, E.C., publish a manual of sign-writing under the title of "Letter-painting," price 1s.; but you will find a list of all such books in Calvert's Catalogue, Great Jackson-street, Manchester.)—A SUBSCRIBER'S SISTER. (It is early in the year for an attack of hay-fever. Mr. Gordon, who has closely studied this disease, considers that the exciting cause is due to the irritation of the air-passages by the odoriferous particles arising from the *Anthoxantum odoratum* or sweet-scented vernal grass. The best remedy is a change to the seaside for a few weeks. Failing that, the use of a good respirator may be beneficial. Some patients have found relief by washing out the nose with a weak solution of quinine.)—T. W. (You are awkwardly placed; but if you can prove the facts, we should advise you to sue the advertiser in the Manchester County-court for the money paid, and for the expenses you have been put to. We can only interfere where an advertiser fails to supply goods, and not in cases where matters are in dispute.)—NE SUTOR ULTRA CREPIDAM. (The discussion to which you object was started—as many readers know—by a correspondent who is a clergyman of the Church of England, so that we think religion is in little danger. Some of your objections we share ourselves; but we do not think we are called upon to stop a controversy when it is naturally raised, as in the present instance, although, of course, it cannot be continued very long, to the exclusion of more practical matter.)

**Dr. Carter Moffat's Ammoniaphone** (Harness' Patent). This excellent invention for strengthening and improving the voice, and for curing ASTHMA, BRONCHITIS, and all pulmonary affections, of which a full description, illustrated by a sectional view of the instrument, appeared in the ENGLISH MECHANIC for Dec. 26th, has been secured by the Medical Battery Co., 205, Regent-street, London, W. Its efficacy is vouched for by the highest medical, scientific, and social authorities, and Dr. Carter Moffat attends daily at 205, Regent-street, London, W., to demonstrate its extraordinary utility. Residents at a distance should write for "The History of the Ammoniaphone," sent post free to any address. Dr. Carter Moffat's Ammoniaphone will be sent post free to any address on receipt of P.O.O. or cheque value 21s., and payable to C. B. HARNESS, The Medical Battery Co., 205, Regent-street, London, W.—[ADVT.]

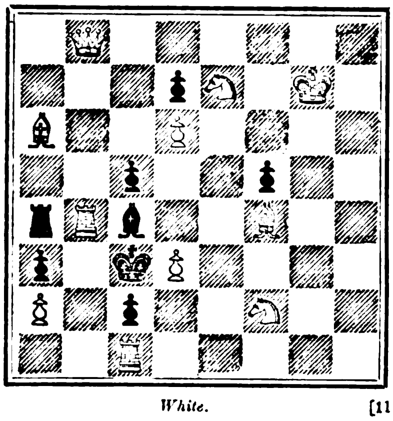
## CHESS.

◆

ALL Communications for this department must be addressed to J. PIERCE, Llandwrog, Carnavon.

### PROBLEM DCCCCXXXII.—By J. PIERCE.

*Black.*



*White.* [11+8

**White to play and mate in two moves.**

SOLUTION TO 930.

| *White.* | *Black.* |
|---|---|
| 1. Q-Q B 2 | 1. Anything |
| 2. Q or Kt mates. | |

(Four variations.)

The K B should be at K R 3, to avoid a second solution.

### NOTICES TO CORRESPONDENTS

CORRECT solutions to 929, by W. Brice, Penge; R. A. Bennett, E. Stanley Follwell, J. E. Piper, R. Holster Raymond, Capt. V. S. Pochin, and S. L. Chivers.

To 930 by Rev. W. Anderson (Old Romney), Raymond, Edith Hughes, R. A. Bennett, W. T. Bayne, S. L. Chivers, J. E. Piper, E. Stanley Follwell, and V. S. Pochin.

A THIRD problem received from Respice Finem.

TOURNEY games received from G. H. Mainwaring (2), J. Russell, Rev. Dr. Healy, and C. W. Last.

J. CULMER.—A dual consists in a second solution after the first move on the part of Black in any of the variations.

E. S. FOLLWELL.—There is only one solution competition for two and three movers together. Why not try at both?

EDITH HUGHES.—There is no mate in your solution of 929 if 1 $\frac{\quad}{R \times R}$.

THE first Tourney Problem will be published in the next number, and the Solution Competition will then begin; all variations which lead to different solutions must be given. Additional marks will be scored if duals or second solutions are discovered.

THE following is at present the score among the first six competitors in Correspondence Game Tourney:—

| | Won. | Lost. | Played. |
|---|---|---|---|
| Vincent | 9½ | 0 | 10 |
| Nash | 9 | 1 | 11 |
| Russell | 9½ | 1 | 11 |
| Bourn | 8½ | 2 | 12 |
| Blake | 7½ | 1 | 9 |
| Chatto | 7 | 0 | 8 |

The total number of games to be played is fifteen.

**Every Workman** connected with the Building Trades requiring a Situation should advertise in "THE BUILDING NEWS," published every FRIDAY, price Fourpence, at 332, Strand, London, W.C.

"THE BUILDING NEWS" is the Principal Journal representing Architects and Builders, and has the largest circulation of any Professional Journal in the kingdom.

Every Workman should insist on seeing "THE BUILDING NEWS" every week at his Club or Coffee House. He will find more "Lists of Tenders" for new work in it every week than in any similar paper, and can thus judge where work is likely to be had. He is also specially invited to make use of "Intercommunication" if he wants to know anything about his trade; to write to the Editor if he has any suggestions to make, and to advertise in the paper when he wants work.

The charge for Advertisements for Situations is One Shilling for Twenty-four Words, and Sixpence for every Eight Words after

## CHARGES FOR ADVERTISING.

*\.* It must be borne in mind that no Displayed advertisements can appear in the "Sixpenny Sale Column." All advertisements must be prepaid; no reduction is made on repeated insertions; and in cases where the amount sent exceeds One Shilling, the publisher would be grateful if a P.O.O. could be sent, and not stamps. Stamps, however (preferably halfpenny stamps), may be sent where it is inconvenient to obtain P.O.O's.

The address is included as part of the advertisement, and charged for.

Advertisements must reach the office by 1 p.m. on Wednesday to insure insertion in the following Friday's number.

£6,000 IN PRIZES GIVEN TO SUBSCRIBERS!

EVERY SUBSCRIBER GETS A PRESENT.

Everyone Gets a Present. All of the above Presents will be awarded in a fair and impartial manner, full particulars of which will be given hereafter.

THE GOLDEN ARGOSY Is a Weekly Paper for the Father, the Mother, the Boys and the Girls. It is one of the most Beautiful, Useful, Entertaining, Instructive and Popular Weeklies published. It is Beautifully Illustrated, and its reading matter is all Original, from the pens of noted authors. Its regular subscription price is Two Shillings for Three Months; Four Shillings for Six Months; Eight Shillings for Twelve Months, without present or premium; but in order to secure 100,000 new Subscribers, at once, we make the FOLLOWING LIBERAL OFFER:

FOR TWO SHILLINGS or 26 Stamps, we will send you The Golden Argosy, WEEKLY, for Three Months, and one numbered receipt, good for one present. For Four Shillings, or 52 stamps, we will send THE GOLDEN ARGOSY, weekly, for Six Months, and two numbered receipts, good for two presents. For Eight Shillings, P.O. or cash, we will send THE GOLDEN ARGOSY, weekly, for One Year, and four numbered receipts, good for four presents. Every Subscriber gets a receipt, and is entitled to a present for each receipt. Write your name and address plainly.

YOUR SUBSCRIPTION FREE. If you will Cut this Advertisement Out and show it to your friends, acquaintances and neighbours, and get five to subscribe for three months, and send us Ten Shillings, all at one time, we will send you your subscription Free, and One numbered receipt; get ten to subscribe, send 20s., all at one time, and we will send you Two numbered receipts and the Golden Argosy for Six Months; get twenty to subscribe for three months, send 40s., all at one time, and we will send you the Golden Argosy for One Year, and Four numbered receipts, good for Four Presents. A little work will give you a Subscription Free, and a chance to win one of the most valuable prizes. P.O.O. preferred. SAMPLE COPIES 2d. post paid, or all Newsagents.

NOTICES FROM THE PRESS.

A new candidate for the favour of patrons of periodical literature is the English edition of the "Golden Argosy," a weekly paper whose American edition has for some time past been enormously popular on the other side of the Atlantic. Its contents are interesting, wholesome, and good, without being goody, and the paper seems to have class enough to run upon its own merits. The proprietors, however, announce their intention of giving away among their subscribers, under certain conditions, prizes to the value of £6,000 sterling.—The Referee, London.

We have received the early numbers of the English edition of the "Golden Argosy," a weekly journal containing much that is interesting. The serial stories are ably written, and the paper abounds with matter of a highly entertaining description, while the illustrations, which are numerous, are characterised by refinement and finish. It is exceedingly well printed on rolled paper.—Morning Advertiser, London.

The "Golden Argosy," as a publication, has everything in its favour. It is well and clearly printed on good paper, beautifully illustrated, and not the least of its recommendations is the fact that, the literary matter is of a high order, and makes it fit to circulate in any home.—The Liverpool Weekly Albion.

The "Golded Argosy."—As the subscription is only two shillings per quarter for an excellent illustrated weekly budget of literature, it is not improbable that the number of their subscribers will soon be enormous.—The Lancaster Guardian.

We think the paper ought to become popular. There are three good reasons why it should do so, these being—it is well printed and illustrated, the subscription is only eight shillings a year, and the whole space is occupied with reading matter, there being no advertisements. Happy newspaper property, not to require them!—Whitehall Review, London.

The paper abounds with excellent stories, elevating and pure in tone, and with "funniosities" of every imaginable kind, which cannot fail to be productive of mirth and good humour.—Belfast News-Letter.

WHAT SUBSCRIBERS SAY.

"Received 'Golden Argosy' papers safely; words fail me to express my entire satisfaction of same. I anticipate at least one year's pleasant reading. Shall continue to recommend so valuable a paper, which is not only humorous and witty, but instructive.—Wishing you every success, A. TILLY, Guyde-Dome, France."

"We consider the 'Golden Argosy' a most interesting paper for both old and young, for the latter just entering life, it is invaluable, conveying as it does useful knowledge with good sound advice and high moral teaching.—E. HIBBERT, Elm Villa, New Road, Chatham."

"I enclose 2s. and mean to be a regular subscriber, and wish you success.—J. FINCH, Mold Green, Huddersfield."

"Am well pleased with the 'Golden Argosy;' it is a high class family paper, and worthy of a place in every household.—J. EVERTON, 1, Duncombe Street, Grimsby."

"I must say the 'Golden Argosy' far surpasses my most sanguine expectations, the reading is far above the average weekly journal.—J. R. SHAW, Carrickfergus."

"I enclose 2s. to extend my subscription. I can say it is the 'Golden Argosy' in value.—With best wishes, J. FENTIMAN, 15, Eldon Street, Bury."

"I enclose 6s. to extend our subscriptions. I like the paper very much, and think it very good.—E. MUSGRAVE, Sowerby."

"I am much pleased with your 'Golden Argosy,' and enclose 6s. for the remainder of the year.—C. HALFORD, Dogsthorpe Road, Peterboro'."

"I have received 10 copies of the 'Golden Argosy,' and my sons and daughters are very pleased with it. I enclose 6s. to make up a year's subscription.—Mrs. S. HOWORTH, Mirfield, Yorks."

Hundreds of Testimonials like the above received daily.

LIST OF THE AWARDS will be printed in the "Golden Argosy," and forwarded to all subscribers immediately after MAY 16th. Remit by P.O. or Registered Letter. Address—

THE GOLDEN ARGOSY CO., E. B. LEWIS, Manager, 13a, Salisbury Square, Fleet Street, London, E.C.

REMEMBER, the above Presents are given absolutely free to our Subscribers and Agents. CUT THIS OUT and show it to your friends, neighbours, and acquaintances. It may not appear again.

## TERMS OF SUBSCRIPTION.

PAYABLE IN ADVANCE.

6s. 6d. for Six Months and 13s. for Twelve Months, Post-free to any part of the United Kingdom. For the United States, 13s., or 3 dols. 25c. gold; to France or Belgium, 13s., or 16f. 50c.; to India (via Brindisi), 15s. 2d.; to New Zealand, the Cape, the West Indies, Canada, Nova Scotia, Natal, or any of the Australian Colonies, 13s.

The remittance should be made by Post-office order. Back numbers cannot be sent out of the United Kingdom by the ordinary newspaper post, but must be remitted for at the rate of 4d. each to cover extra postage.

Messrs. JAMES W. QUEEN and Co., of 924, Chestnut-street, Philadelphia, are authorised to receive subscriptions for the United States for the ENGLISH MECHANIC, at the rate of 3 dols. 25c. gold, or Thirteen Shillings per annum, post-free. The copies will be forwarded direct by mail from the publishing office in London. All subscriptions will commence with the number first issued after the receipt of the subscription. If back numbers are required to complete volumes, they must be paid for at the rate of 4d. each copy, to cover extra postage.

Vols. IV., VII., XXVI., XXVIII., XXX., XXXII., XXXIII. XXXIV., XXXV., XXXVI., XXXVII., XXXVIII., XXXIX. bound in cloth. 7s. each. Post free, 7s. 9d.

Vol. XL. ready shortly.

All the other bound volumes are out of print. Subscribers would do well to order volumes as soon as possible after the conclusion of each half-yearly volume in February and August, as only a limited number are bound up, and these soon run out of print. Most of our back numbers can be had singly, price 2d. each, through any bookseller or newsagent, or 2½d. each, post-free from the office (except index numbers, which are 3d. each, or post-free 3½d.)

Indexes for Vols. I., VI., VII., VIII., and IX., 2d. each. Post free 2½d. each. Indexes to Vol. XI. and to subsequent vols., 3d each, or post free, 3½d. Cases for binding, 1s. 6d. each.

## NOTICE TO SUBSCRIBERS.

Subscribers receiving their copies direct from the office are requested to observe that the last number of the term for which their subscription is paid will be forwarded to them in a PINK Wrapper, as an intimation that a fresh remittance is necessary, if it is desired to continue the Subscription.

**Epps's Cocoa.**—Grateful and Comforting:—"By a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by a careful application of the fine properties of well-selected Cocoa, Mr. Epps has provided our breakfast tables with a delicately flavoured beverage which may save us many heavy doctors' bills. It is by the judicious use of such articles of diet that a constitution may be gradually built up until strong enough to resist every tendency to disease. Hundreds of subtle maladies are floating around us ready to attack wherever there is a weak point. We may escape many a fatal shaft by keeping ourselves well fortified with pure blood and a properly nourished frame."—*Civil Service Gazette.*—Made simply with boiling water or milk, Sold only in packets, labelled—"JAMES EPPS and CO., Homœopathic Chemists London."—Also makers of Epps's Chocolate Essence

**Holloway's Ointment.**—Go where you may, in every country persons will be found who have a ready word of praise for this Ointment. For chaps, chafes, scalds, bruises, and sprains, it is an invaluable remedy; for bad legs, bad breasts, and piles, it may be confidently relied upon for effecting a permanent cure.

"**Lantern Manipulation,**" 3d. post, gives instructions, management, and making lime and oil lights.—POMPHREY, Stanhope-street, Birmingham.

10,000 **Lantern Photographs,** 6d. plain; 1s. coloured. List, 140 pages, facsimile illustrations, 100 sets, 6d. post.

**Pocket Tripod,** patent, for professionals and amateur photographers, cyclists. Particulars, illustrations, and testimonials to be had on approval.—A. POMPHREY, Stanhope-street, Birmingham.

**Lantern Readings** to 100 sets slides, with facsimile illustrations, 80 sets for 2s. 3d.—POMPHREY, Stanhope street, Birmingham.

**Marking-ink Pencil**; satisfactory or money returned; 7 stamps.—JAMES PARKINSON, 45, Sankey-street, Warrington.

**Steel V Gauge** for grinding screw-cutting tools to post free, 7d.—HOLLOWAY, 39, Reservoir-road, Birmingham.

**Covered Magnets** for making magnetic appliances, 1s. per dozen.—Address, No. 1, Victoria-terrace, Ryecroft-hill, Walsall.

3¼ Wray **Telescope,** strong garden stand, first-class instrument. Test objects given.—T. CLAPHAM, Austwick, Lancaster.

**Tricycles.** — Singer's "Apollo," "Traveller," and "Telescopic," quite new and unused; giving up agency. Five shillings in the pound off list.—FALKNER, Ironmonger, Southport.

**Mica,** otherwise Talc.—RICHARD BAKER & CO., 9 Mincing-lane, London.

Gramme **Dynamo Machines,** sound and well made, suitable for lighting shops, &c. Expressly made for long running; long bearings, massive fields; 100 candle power, £6 10s.—A. ASHBY, 184, King's-road, Chelsea.

For Sale.—Double acting **Hot Air Engine,** ½ h.-p.—Apply, J. A., 46, Frith street, Soho, W.

Circular **Stocks and Dies,** for cutting full threads at once running down. A great improvement on the old style. See testimonials. List one stamp.—JERMY and SON.

**Testimonial.**—"Gentlemen,—I am very satisfied with the screw-tackle. It is certainly a novelty. It is particularly well suited for Amateur Mechanics and small Manufacturers." For full copy of this and other testimonials send for lists.—JERMY and SON, North-street, Stafford.

**Barometer Standard,** by Troughton, in glass case, complete, value £20, to be sold for £6. Write for appointment to see.—A. B., 4, Blackfriars-road.

Silver English **Lever Watch,** almost new, capital timekeeper, £3 10s., cost £6 10s. If not approved of, money returned.—R. HOLT, Church-street, Radcliffe, Manchester.

Large **Yellow Daisy Seed,** 7d. post free; also Gigantic Lemon Sunflower Seed, 6d. post free. Sold for a charity. —Miss N. B., Wrentham Rectory, Suffolk.

Beautiful toned lion head **Violin,** labelled "Antonius Stradivarius, Cremon, 1632," with silver mounted bow and brass mounted case. Price 15s. Bargain. Inspection invited, or address AMALIA GILDERS, Schoolyard House, Brightlingsea, Essex.

Beautiful **Model Engine,** 1 inch bore, 2 inch stroke, on bay wood stand, £2.—A. LEE, 6, Starkey-street, Heywood, Lancs.

For **Price List** of Batteries, Bells, Insulated Wire, Coils, Chemicals, &c., apply to SHAW and Co., Wood Green.

100 **Foreign Stamps,** including Brunswick, Ceylon, Tasmania, Egypt, Greece, Luxemburg, free 7d.—HELY, Foley-street, London.

For Sale, a Set of Mr. Bottone's **Dynamo Castings,** with hand wheel and bolts fitted, 11s.—MITCHELL, Holden Park-road, Southborough, Tunbridge Wells.

Wray, second-hand, 3¼ inch aperture **Telescope,** three astronomical and one terrestrial eyepiece, finder, dew-cap, pillar and claw stand, pine case, garden tripod, practically good as new, £17 10s.—Laurel House, Highgate, N.

"**English Mechanic and World of Science,**" from June, 1870, to present date, except Vol. XIV., in monthly parts. Good condition.—Apply E. H. M., 564, Fulton-street, Brooklyn, N.Y., U.S., with offers.

**Water Engine,** vertical, by Robinson, tool maker, for lathe work, all fittings, quantity of 1¼ inch piping, £8, bargain.—PILKINGTON, Lune-street, Preston.

**Countershafting,** 2 inches, cone pulleys, hangers, brackets, useful lengths, £1 10s.—Address, PILKINGTON, above.

**Lathe,** Headstock, and Back Poppet, 9 inch centre, adjustable, countershaft, cone pulley £1 10s., bargain.

**Entomologist's Cabinet,** six drawers; rare moths, butterflies, three books on subject, 12s. 6d. lot, not perfect.—Address, PILKINGTON, above.

**Microscopic.**—Well mounted Slides for sale. List and sample 8 stamps.—TURNELL, Victoria Pharmacy, Victoria-road, N., Southsea.

Have several good **Sewing Machines** to sell cheap, from 15s.—E. PHILPOT, 15, Mercery-lane, Canterbury.

**Spiral Springs.**—Odd Spiral Spring made on the shortest notice; mattress springs 9d. per dozen, invalid chair and couch springs 9d. per dozen. Send for sample.—JAMES PARISH, 52, Bard-street, Park, Sheffield.

A **Comic Love Letter,** Negro Sermon (intensely amusing), Matrimonial Puzzle, &c., &c., 7d. only.—F. DALTON, Charles-street, Wisbech.

**Kitchener,** second-hand, nearly new, high-pressure boiler, two large ovens, 5ft. 6in. high, 4ft. wide.—J. M., 7, Lamb-street, Spital square, E.

**Catapults,** 7d., 1s., 1s. 2d.; elastic 2d., 3d. foot; square 1d. to 4d. yard.—MOODY BELL, Cheltenham.

**Fly-Wheel,** 3ft. diameter, rim 2½in. by 4in., turned, price 10s. 6d.—JOHN CASS, Eagley, Bolton.

**Sledge, Wyatt, and Co.** are now making a new **Bell** at 3s. 6d. each.—95, Wirtemburg-street, Clapham, S.W.

The "Specialité" **Electric Bells** have polished mahogany cases, double coils, silver contacts, &c., 3s. 6d. each; free 4s.

The "Specialité" **Electric Bells,** 2½in. plated gongs, brass terminals, lugs, and fittings.—SLEDGE, WYATT, and Co, Clapham.

The "Specialité" **Electric Bells,** 3s. 6d. each. Cheaper than amateurs can make them; best in the trade.

The "Specialité" **Electric Bells,** sent complete to any address on receipt of 4s.—SLEDGE, WYATT, and Co.

**Hand Dynamos,** £2 10s. each, sent free on receipt of cash.—SLEDGE, WYATT, and Co., Clapham.

**Single Needle Instruments** (pedals), with battery, 30s. each.—SLEDGE, WYATT, and Co., 95, Wirtemburg-street, Clapham.

**Sounder and Key,** with Battery (P. O. Pattern). Complete set, 30s.—SLEDGE, WYATT and Co., Clapham.

**Electric Light Switches** (mains), 6s. each; single light (very neat), 2s. each.—SLEDGE, WYATT, and Co.

**Sledge, Wyatt, and Co.,** Electrical Engineers and Contractors, 95, Wirtemburg-street, Clapham, S.W.

**Billiard Table,** 6 by 3½, slate bottom, mahogany frame, re-covered, balls, cues, and marker complete, £6 5s., cost £30.—D. TAGGART, Bushmills, Ireland.

**Carte Lens,** double combination, mahogany camera, and slides complete, 25s., genuine.—J. PEPPIATT, Sarratt, Rickmansworth, Herts.

**Bicycle,** 52in., "Timberlake," good roadster, splendid condition, £7.—E. HAYNE, 48, Ashley-road, Crouch hill, N.

**Microscope Slides,** 12, 1s. 4d. Lot of mounting requisites. List sent free.—LINTIN, 170, Freedom-road, Sheffield.

**Hand Drilling Machine,** drills ¾ inch holes 6 inches from edge, 25s. Photo 3 stamps.—S. BEECHING, Mareham-le-Fen, Boston.

**Carburetters** to "Arvonia's" Drawings; warranted strongly made, sound, and cheap.—E. WOOLLEY, 22, Jessell-street, C. on M., Manchester.

**Lathes.** — Various parts, rough or finished, best materials. Stamp.—CAMERON, 72, Great Percy-street, W.C.

Model **Engine Castings.** Best and Cheapest. See list (stamp) and compare.—WOOD, Dalley-street, Broughton, Manchester.

Model **Boilers** from 7s. 6d. each, fitted complete, tin and copper sheet.—J. W. M., 41, Cross-roads, Upper Wortley, near Leeds.

"**E. M.,**" from 1880 to present time, clean and complete, half price.—J. ENDEAN, 15, Holland street, S.E., London.

**Printing Presses** from 10s., complete. Instructions to amateur printers, just published, post free 1½d.—ADAMS, Daventry.

**Photo Apparatus,** half-plate, Ross lens, a bargain. —G. V. B., 12, Hereford Gardens, W.

**Bichromate of Potash,** 6½d. per lb.—H. LOFTING, 2, Tournay-road, Walham Green, S.W.

Books.—"**How to Live on Sixpence a Day,**" Post free 3d.—LOFTING, 2, Tournay-road, Walham Green.

"**See-Saw Waltz,**" post free 1s. Also quantity of songs, &c.—LOFTING, 2, Tournay-road, Walham Green.

**Electric Bell,** Battery, Push, 20yds. Wire, carriage free 9s. 6d.—FRANKLIN.

Portable **Bell,** Battery, Push, 20yds. Wire, in stained and polished pine case, carriage free 10s. 6d.—FRANKLIN.

**Wholesale Bell and Battery Maker,** Indicators, Induction Coils, Carbons, Terminals, Wires, &c.—FRANKLIN, Volta Works, 41, Sherman-road, Reading.

**Electrical Battery Apparatus,** polished mahogany case, 8s. 6d.—HOWARD, 290, High Holborn.

52in. D. H. F. "Premier" **Bicycle,** ball bearings, nearly new, £7 10s., very cheap.—HOWARD, 290, High Holborn.

**Tricycle,** "The Merlin," ball bearings, excellent condition, cost £18, price £7 10s., bargain.—HOWARD, 290, High Holborn.

**C. Pilkington,** 32, Sackville-street, Piccadilly, W., Magic Lantern Artist and Photographic Colourist.

Magic Lantern **Photograph Colouring,** finely and artistically done, 14s. per dozen. Special terms to the trade on application.—C. PILKINGTON, 37, Sackville-street, W.

**To Bell Fitters and Others.**—Write for reduced List of Bells, Leclanche Batteries, and Materials for same.

**Bell Fitters' Sundries** supplied. All Goods guaranteed.—JOHN H. HINDLE, Irwell Vale, Helmshore, near Manchester.

Twisting, Reeding, and Fluting **Lathe.** While inventing the spiral lathe my aim has been to make it in as few parts, to lessen the friction, and make it as cheap as possible, so that it may be within the reach of every woodturner. I have done small pillars of stone, coal, and clay. Will some one make an offer for it?—Scott.

Steel **Name Stamps,** 3d. per letter. Figures (set), 2s. 4d. Letters, 6s. 4d., per post.—E. F. Baldwin, Robinswood-hill, Gloucester.

**Name Burn Brands,** 5d. per letter. Indiarubber Name Stamps, 1s. 8d. per post.—E. F. Baldwin, Robinswood-hill, Gloucester.

**Books.**—"Mechanic's Workshop Companion," 5s. 6d.; "Engineer's Machinist's Practical Assistant," 2s. 9d., per post.—E. F. Baldwin, Robinswood-hill, Gloucester.

**New Time.**—Alter your Clocks and Watches. Twelve Sets of Figures, with instructions, 6d.—Wheeler, Preston.

**Water Motors,** for sewing machines, organettes window advertisements, 32s., 42s. List one stamp.—Wheeler.

**Fan Castings.**—Improved Registered Designs; sets 5in., 3s.; 6in., 4s.; 8in., 5s. Drawings, 4d.—Wheeler, Engineer.

**Water Motors.**—Complete one horse-power, £9. Half, £6. Quarter, £4. Eighth, £3.—Thomas Wheeler, Preston.

**Incandescent Carbon Lamps,** low resistance, 3s. each; Fairy Lamps, 3s. 6d.; Platinum Lamps, 1s. 3d., post free.—Todd, 14, Wentworth-road, Manor Park, Essex.

**Incandescent Lamp Holders,** new pattern, best in the trade, 12s. dozen; sample, post free, 1s. 3d.—Todd, as above.

The **Coca Leaf Season** has commenced. The best and safest stimulant. Sample packet 13 stamps.

**Coca, or Cuca Leaves.** Taken out by many of the troops in the Soudan. Bought of Marks and Co.

Hunger Defied.—All Cyclists do, or should, carry **Coca** Leaves. Medical and Scientific opinions included with packet.

Every **Volunteer** certainly should take a packet to Brighton. Coca is a necessity, dinner is not.

The tired and weary **Pedestrian** will be resuscitated as if by magic by chewing a few leaves.

**Coca Leaves.**—Medical and scientific opinions included. Sample packet 13 stamps.—Marks and Co., 17, Newcastle-street, Farringdon-street, E.C.

**Violin,** labelled "Antonius Stradiurius Cremonensis faciebat, Anno 1650," marvellous rich tone, handsomest orchestral solo instrument in England; fine preservation; suit professional; with excellent bow, resin, and superior brass-mounted case. Sacrifice whole lot for 14s. 6d., carriage paid; supposed very valuable. Inspection invited, or send early and secure this genuine bargain.—Thomas Carr, Bandmaster (51), Brightlingsea, Essex.

**The Perfect Pea Trainers** (Patented). Send for price list to Thomson's Seed Warehouses, Horticultural Implement and Beehive Depot, 20, High-street, Birmingham.

Tudsbury and Sons' "High Tension" **Wimshurst** Machines, with their new compound ebonite plates, more powerful than glass, unbreakable. Price, 16in., 65s.; 12in., 48s.; 8in., 30s. List, one stamp.—Edwinstowe, Newark.

**Piano,** a good square for sale, £2 10s. Also a good Banjo, cheap.—Apply, first by letter, to E. Leland, jun., 19, Carlton-road, Mile End, E.

**Gelatines,** for tracing Magic Lantern Slides, 4½d. per doz.—Address, Photo, 182, Trongate, Glasgow.

Fine Astronomical **Telescope,** by Mills, 2¼ o.g., rack adjustment, two eyepieces, brass tripod, £4.—99, City-road.

Large Chemical **Spectroscope,** new, £14. Rhumkorff Coil, and five choice Vacuum Tubes, 35s.—99, City road.

Tisley's **Harmonigraph,** 63s. Elliott's Reflecting Galvanometer, £. Browning's Magnetic Exploder, £3 10s. Astro. Eyepieces.—99, City-road.

**Mesmerism.**—All can mesmerise. Success certain. Never fails. Instructions, 8 stamps.—See below.

**Thought Reading.**—Instructions which will teach anyone to become a thorough thought reader in a few hours, 8d.—Below.

**Clairvoyance,** or Second-Sight.—For 8 stamps will forward instructions which will teach anyone. All three, 13d.—G. Marquis, Allhallowgate, Ripon.

Screw-Cutting Gap **Lathe,** 3in. centre, beautifully finished, 8 guineas. Bargain.—Halls, Howard-street, Yarmouth.

**Engineer's Business** for immediate disposal as a going concern in busy part of Southwark and near the Borough; first-class plant and premises and good connection, and one or two specialities in hand.—Apply to S. S. Bromhead, 97, Newgate-street, E.C.

**Dynamos,** hand or power, lamps, &c.; low prices; bargain. Stamp.—Warne, 39, St. John-street-road, E.C.

**Lathe Heads and T Rest,** for woodturner, 30s. Launch Engines, Boilers, and Propellers.—Chennall, Eastville, Bristol.

**Bicycle,** 52in., Haynes and Jefferies' "Coventry." Excellent condition. Cash price, £3 15s.—D. Blagrove, High-street, Lewes.

**Slide-Rest** for 2½in. Lathe, in good order, cheap, 12s. 6d.—J. Brooks, West-street, Alford, Lincolnshire.

Your **Photograph Copied** equalling original, mounted on best cards. Six, 2s. Twelve, 3s.—C. W. Bickle, Stoke, Devonport.

Splendid 12in. polished Steel **Fret Frame,** 1s. 6d. free. Twenty assorted Fretwork Patterns, 7d.—C. W. Bickle, Stoke, Devonport.

Beginner's **Bicycle,** 48, "Ariel," rubber treadles, lamp, gong. Going order. Offers.—Betts, 120, Gwydir-street, Cambridge.

**Elastic Stockings** for Varicose Veins.—W. Smith and Sons, 37, Breck-road, Liverpool. None made in London.

Artistic Hand-painted **Plaques,** ½ inch, velvet frames, 7s. 6d. the pair.—Studio, 34, Denmark-road, Manchester.

**Electric Motor.**—All parts and full instructions for making a real working model, 1s. 3d., free.—Theobald.

Double **Opera Glass,** lenses, metal parts, covering, and instructions for making good glass, free, 1s. 3d.—Theobald.

**Electric Bell,** Gong, Core, Wire, and all parts, and instructions for making, free, 1s. 3d.—Theobald.

**Pantographs,** full size, for mechanically enlarging maps, plans, designs, photographs, &c., with instructions, 1s. 2d., free.—Theobald.

Leclanché, Daniell's, and Bichromate **Batteries,** 1s. 3d. each, free.—Theobald, 11, South-street, Greenwich, London, S.E.

**Cat Gut.**—Gut Hooks and Eyes for lathes and machinery.—James Bellairs, Regent-street, Leicester.

**Bellairs' Gas Stoves,** 1s. 3d., 2s. 3d., 3s. 3s., for boiling. Breakfast stoves, 8s., 11s., 14s. 6d. Send for lists.

Cookson's superior Brass **Engine Castings.** Best and cheapest in the trade, horizontal, ¾ bore, 1½ inch stroke, with guide bars, 3s.

One inch Bore, 2in. Stroke, 4s. 6d.; with guide bars, 5s.; with steam ports made, same price; boring cylinders, 6d.; ¾ do., 4d. extra.

**Engines,** Boilers, and separate parts. Send stamp for list.—S. Cookson, Rovenscliff-road, Kidsgrove, Staffordshire.

New Half-Plate Folding **Camera,** rising front, side screw adjustment, two double slides, £2.—W. Saunders, Dickleburgh, Norfolk.

**Lathe,** 5in. screw-cutting, 5ft. bed, complete, little used, £17 10s.—John Middleton, 16, Hope street, Glasgow.

**Lathe** for sale, back-geared, 5in. centres, compound slide-rest, &c.—John Middleton, 16, Hope-street, Glasgow.

The Simplified **Pentagraph.**—Will enable anyone without a knowledge of drawing to copy and enlarge photographs, pictures, or drawings. Sent free on receipt of 9d. stamps.—Phillips, Optician, 126, Chatsworth-road, Lower Clapton.

**Mandrel Drawn Tube,** brass or German silver, large or small quantities.—James Wilson, Manufacturer of Fishing-rod Mountings, &c., 63, Argyle-street, Glasgow.

**Microscope Objectives,** best quality, to be sold cheap. A 3in., 1in., 1-6th, ¼th, 1-12th water immersion.—E. S., 105, Myddleton-road, Hornsey.

**Cyanotype Paper,** 4d. per sheet, specimen free.—Humphries, Photographer, 5, Esher villas, Shadwell-road, Holloway, London.

Magnificent machine-head **Guitar,** inlaid, equal new, very handsome. Free for 9s. 6d.—Thomas Carr, Brightlingsea, Essex.

**Lathes** and separate parts, rough or finished, or with machine work done. See revised list.—W. R. Smelt.

**Turning,** Boring, Screw-cutting, Planing, Patterns, Forgings, &c. Best workmanship at reasonable prices. Estimates free.—W. R. Smelt.

**Models** of Machinery and Mechanical Movements for Inventors and Manufacturers to scale or otherwise. Estimates free.—W. R. Smelt.

Revised **Lathe List** 1 stamp.—W. R. Smelt, Engineer, 7, Goldsmith's-row, Gough-square, E.C.

Compound **Slide-Rest** and best self-centring chucks, cheap. State requirements.—John Middleton, 16, Hope-street, Glasgow.

**Edward W. Drury,** Hull, Glass Bottle and Cork Manufacturer, Importer of Chemicals, Caramel, Glucoses, Tinned Wire.

**Microscopic Glass Slides,** smooth edge, 5s. per gross.—H. Howard, 7, Chichester-terrace, Shepherd's Bush, W.

Thin covers 3s. per ounce; **Cells,** smooth edge, 14s. per gross; troughs, media, &c.—H. Howard.

**Marine Glue,** Canada Balsam, and all preparations, 6d. per bottle.—H. Howard, as above.

**Amberine.**—Recipe for the best non-alcoholic drink 1s.—H. Parkinson, 7, Chichester-terrace, Shepherd's Bush, W.

Warming, Cheering, Invigorating.—**Amberine,** the best drink. Recipe, 1s. stamps.—H. Parkinson, as above.

**Medical Coils,** very powerful, with battery, complete, carriage free, 2s. 9d. Marvels of cheapness. See below.

**Batteries,** Bichromate, 1s. each, carriage free, 1s. 3d., very powerful, for working coils, motors, &c.—See below.

**Batteries,** Daniell, 1s. each, carriage free, 1s. 3d. very useful for electroplating, &c.—See below.

**Batteries,** Leclanché, 1s. each, carriage free, 1s. 3d., sealed, constant and powerful, for electric bells.—See below.

**Electric Bells,** 7s. 6d., complete set, comprising powerful plated bell, battery, push, line wire.—See below.

**Electro-Plating Apparatus,** 2s. 6d., carriage free, 2s. 9d. Complete apparatus and instructions for amateurs.—See below.

**Toy Gas Motor,** carriage free, 1s. 9d., fit any gas burner, gives brilliant revolving light.—See below.

**Shocking Coil Parts,** 1s., carriage free, the complete set, with instructions for amateurs.—See below.

**Flying Rattle Snakes,** free, 1s. 7d., create roars of laughter and great consternation; made of rubber tissue, blow out 4ft. long, and give forth blood-curdling screams if stroked the wrong way.

**Electric Bells,** 1s., post free, 1s. 3d., all the parts and full instructions for amateurs to construct.

**New Price List,** containing all electrical sundries at really economical prices, free, one stamp.—See below.

**Covered Wire,** silk and cotton, cheapest in the trade. See list.—Economical Electric Supply Co.

For all the above articles, address—Manager, M Department, Economical Electric Supply Co., Wood Green, London.

**Formulas Worked Out** for winding Dynamos from 10 c.-p. to 500 c.-p., 8 stamps each.—H. Jones.

**Dynamo Castings,** 100 c.-p., cog armature, Gramme fields, 9s. a set. Motors with patent armature, 3s. a set.—H. Jones.

**Dynamos,** patent improvements, No. 2,122. 70 c.-p. machines, £5. 32 volts, 7 ampères.—H. Jones.

**Dynamos,** best small machines in the trade, and cheapest double-covered Wires to 20 gauge, 1s. 8d. lb.—H. Jones.

**Dynamos** for Home Lighting.—5 lights, or arc of 500 c.-p. Price £6 10s., approval. Warranted.

**Dynamo Castings,** with laminated armatures, 8 c.-p., 5s.; 16, 5s. 6d.; 20, 6s. 6d.; 30, 7s. each.—H. Jones.

**Dynamo,** laminated armatures, no heating, ventilating; 70 c.-p., 16s. a set; finished, £5. Warranted.—H. Jones.

**Dynamo Machines Repaired.** Motors, with wire, 5s. 6d.—H. Jones, 48, High-street, Lambeth, S.E.

**Universal Trade and Amateur Supply.**—Lecture requisites; light, heat, air, water, geology, engineering, chemistry, photography, &c. Wholesale and export.—Caplatzi.

Frictional and **Induction Machines,** Plates Cylinders, Stands, Conductors, Glass, Vulcanite. Hundreds of Lecture Accessories; their Parts.

**Coils.**—Experimental, Resistance, Medical, Dynamo, Bell, Telegraph, Galvanometer, and other purposes. Vacuum Tubes.

**Batteries.**—Thousands Lighting, Experimenting, Medical, Depositing. The Universal Four-cell Case, 18s. Convenient, durable, and economical.

**Coil-making.**—Sets of Parts and Instructions to size; 5, 10, 20s. The brass, woodwork, reels, wire, separate, cheap.

**Dynamos,** Arc and Glow Lamps, Electric Lanterns, Castings. 10 kinds of Motors, Leads, Armatures, Dynamometers.

**Wires.**—Cheapest Stores. New and second-hand. Great reduction in price. Paraffin, Vulcanite, Reels, Brasswork, Cores, various.

**Astronomy.**—"Society's Monthlies," number good Stands, Tubing, Clock Racks, Circles, O.G.'s, Eyepieces, Finders, Prisms; other parts.

**Transit,** 2¼in., by Cary, with circles; good 2, 2½, 3 Telescopes. Several reflectors; great variety of Terrestrials.

**Lenses,** Prisms, Specula, Object-Glasses, Eyepieces, Finders, Cells, Tubing, Racks, Hooks, Joints, Optical Glass, Tools, in quantities.

**Machinery.**—Several good Lathes, Litho, Printing, Stamping Presses, Flatting Mills, Wheel-cutting Engines, Swiss Mandrels, Wire Covering Machines.

**Model Engines** to 2 H.P. Great number of 1, 2, 3in. stroke ones; good boilers, cylinders, gauges, wheels, cocks, pumps, boats.

**Lathes.**—Overhead, Ornamental, 20; Brassfinisher's, 7; Amateur's 3in., 5; Combination, with Fret and Circular Saws, £4.

**Wheels.**—Fly, Lathe, Saw, Engine, Dynamo, Gearing, Pulley, Clock Movements, Large Springs, Bearings, Shafting, Standards, various.

**Screws and Bolts** for Machinists, Model Makers, 60 sizes. Sample 50, 1s., 2s. Screw Plates, Taps, Chasers, Stocks.

**Magic Lanterns,** Slides, Microscopes, Kaleidoscopes. Oil and Lime Burners. Retorts, Bags, Bottles, Condensers, Lamp Reflectors, Lantern Bodies.

**Photography.**—Triplet, Symmetrical, and cheap lenses, Best Stands, Printing Necessaries, double backs, 2 tons of Negatives.

**Slides.**—Superior, painted, comic and effects, Scientific, immense selection. Skilled exhibitors for town and the provinces very moderate.

**Prisms,** Nicols, right-angle, Spectroscope, Camera Lucida, Obscura, Bisulphide, Achromatising, Cylindrical Lenses, Polarising Plates, various.

**Presents.**—50 Microscopes, 100 Accessories, Objects, Cabinets, Powers, Condensers, Stands, Books, exceptionally low prices—2s.-£10.

**Chemistry.**—Fittings-up of complete Laboratories, Copper Troughs, Gasholders, Stills, Baths, Porcelain. Many Balances, Platinum, 2 thirds price.

**Purchases** and Valuations. Fair trade Value. Cash by return, or best selling market indicated. Particulars first.

**Hire.**—Occasional Lecturers and Bazaars will receive good terms, many facilities, with Apparatus of all kinds.—Caplatzi.

New Catalogue, 2d. **Caplatzi,** Science Depot, Hire and Exchange, Chenies-street, Tottenham-court-road, near British Museum.

**Launch Gas Engine.**—Enclose 3 stamps for litho and particulars. A. Dorrington, West Gorton, Manchester.

Half horse-power Horizontal **Engine Castings,** ports in cylinder, 12s. 6d. Drawing, 18 stamps.—A. Dorrington, West Gorton, Manchester.

The Amateur's **Gas Engine.** Simple and compact. Castings, 42s. Drawing, 5s. Litho, 3 stamps.—A. Dorrington, West Gorton, Manchester.

Double Cylinder **Gas Engine,** impulse twice every revolution. Castings, 90s. Litho, 3 stamps.—A. Dorrington, West Gorton, Manchester.

The Amateur's **Drilling Machine.** Castings, 3s. 9d. Forgings, 3s. Drawing, 8 stamps.—A. Dorrington, West Gorton, Manchester.

No. 2 **Drill,** self-acting feed motion. Castings, 7s. 6d. Forgings, 5s. Drawing, 18 stamps.—A. Dorrington, West Gorton, Manchester.

**Launch Engine Castings.**—2in. Cylinder, 12s. 6d., 3in., 26s.; 4in., 5 s.; 7in., 70s. Litho, 3 stamps.—A. Dorrington, West Gorton, Manchester.

3 or 4 jaw **Chuck Castings,** 3s. Forgings, 1s. 2d. Drawing, 6 stamps.—A. Dorrington, West Gorton, Manchester.

**Working Plans,** Lines, and Details of Canoes, Launches, Tugs, &c. State requirements.—A. Dorrington, West Gorton, Manchester.

Enclose Stamp for **List** of Castings and Working Drawings.—A. Dorrington, West Gorton, Manchester.

**Battery,** bichromate, highest electrical efficiency. Contains 10 per cent. more chromic acid than potash bichromate. Lee's new double Bichrome. Soluble in own weight water. 7d. 1lb., 7lb. sample parcels. 6½d. lb. in 56lb. lots.—R. A. Lee.

**Wire,** double cotton-covered, No. 8 to 18, highest conductivity. 2s. per parcels post, 1lb., free. Ditto, 18 to 22, 2s. 3d.—R. A. Lee.

Chaster's **Electro-Motor** (Registered), as described in English Mechanic, Nos. 1026, 1027, 1029, and 1041. Price £4.—R. A. Lee.

Chaster's **Electro-Motor.**—By special permit, R. A. Lee supplies carburetted annealed castings of above, 8s. 6d. set.

Chaster's **Electro-Motor,** planed, bored, and turned throughout, including wire and all materials; price £2.—R. A. Lee.

**Dynamo Machine,** 20-light, continuous working, patent disc armature, low speed, requires ½-h. to drive, £15.—R. A. Lee.

**Electro-Motors,** Batteries, Dynamos. For Lee's other electrical specialities, see advertisements last week.—R. A. Lee, 76, High Holborn, London.

## Wanted.

Old Microscopes, by Adams, Amici, Baker, Dollond, B. Martin, Pritchard (Goring's "Engiscope"), Varley, and other old makers.—J. Mayall, Junior, 224, Regent-street, London, W.

Agency Wanted, for any saleable goods, iron and brass fittings preferred. Good connections. References given.—Address, D., 222A, City-road, London, E.C.

Deer Horns Wanted.—M. Day, Hook and Handle Manufacturer, 56, Driffield-road, Old Ford, London.

Birmingham Goods.—Jewellery, Watches, Clocks, Hardware, Harmoniums, Furniture. Agents wanted. Wholesale catalogues, 500 Illustrations free.—Henry May, Merchant, Birmingham.

## FAC-SIMILE TELEGRAPHY.

ON p. 69, Vol. XXXIX., we gave an account of a rather remarkable system of multiplex telegraphy, then recently devised by Mr. Patrick B. Delany, of New York. In this system, which has since become widely known as the synchronous multiplex, a rotating disc is employed at each end of a single line, and the two discs rotating synchronously connect the line with one set of instruments after the other, so that a large number of messages can be sent forwards and backwards over the one line at the same time. No two transmitting instruments are practically in electric circuit with the line at any one instant, but so rapidly is the "line" taken away and brought back again, that the operator does not notice that he has temporarily been out of circuit. The system has been in practical work for some months between the cities of Boston (Mass.), and Providence (R.I.), a distance of about fifty miles—the apparatus being arranged to work from a single circuit up to seventy-two separate and distinct circuits over the one wire. Two line wires have been erected, in case of accident and for experimental purposes; but it is possible to work with six fast or twelve slow Morse operators, or with thirty-six or seventy-two printing circuits. We need scarcely say that many little difficulties were discovered in actual working, and sundry details needed attention; but the system was soon demonstrated to be a practical success, and is now placed on a commercial basis. The synchronous rotation of the discs, upon which the whole system depends, is maintained and regulated on the "tuning-fork" plan, and experience has shown that when the synchronism has been destroyed by intentional or accidental interruptions, or by breaks in the line wire, the discs at the opposite ends have automatically run into synchronism within 90 seconds without the intervention in any way of the operators at the different stations. Mr. Delany having great ideas of what can be done with this principle of synchronous telegraphy, had the second line wire erected between Boston and Providence for purposes of experiment, and it was not long before he demonstrated the possibility of applying automatic repeaters in connection with his system. Thus, the instruments being arranged for six circuits, the order was as follows: A message started at No. 1 Morse key in Boston was received by the relay at Providence and sent away on circuit No. 2, at the Boston station of which it was again received by a relay and returned to Providence, to be repeated again on No. 3 circuit, and so until it had covered 300 miles, and was finally read at the receiving instrument of No. 6 circuit in Boston. The relays are, of course, worked by local batteries, and, incredible as the results may seem, not a few skilled telegraphists would have believed it impossible to connect the receiving instrument of No. 6 circuit in Boston with the transmitting instrument of No. 1 circuit in the same city, and so compel the message to keep on going over the several circuits until some part of the apparatus failed or the batteries broke down. The original signal keeps passing from city to city without the intervention of any operator, and it was observed by timing the intervals of its return that it passed between Boston and Providence 1,800 times in one minute. The signal actually timed—a dot—was kept passing and repassing for five minutes, in which period it covered a distance of 450,000 miles. It will be understood that the greater part of that period of time was taken up by the movements of the armatures of the receiving relays and the levers of the transmitting instruments; but it is surely a remarkable experiment! Mr. Delany, however, had a far more important idea in training, and from a preliminary announcement by Prof. E. J. Houston, we imagine that Mr. Delany has succeeded in accomplishing what he aimed at, for the *Journal* of the Franklin Institute for March appears with an illustration of fac-simile messages, sketches, &c., sent by means of a crude experimental apparatus over one wire. Fac-simile telegraphy has been accomplished before, notably with Cowper's writing telegraph; but when a single wire only was employed the time was so prolonged, and the uncertainty of reproduction so great, that the system had little chance of being commercially successful. If we interpret Prof. Houston's brief announcement aright, Mr. Delany is on the high road to success, and will shortly give us a method of telegraphing handwriting, sketches, maps, plans—in fact, almost anything—with speed and, what is of perhaps of more importance, with certainty of correct reproduction, for, according to the statement published, by means of the Delany synchronous system, an area of twelve square inches can be covered in one minute. The specimen message reproduced as an engraving, by Prof. Houston, consists of a groundwork of rather coarse lines, which are thickened here and there where the current has passed, and letters, sketches, and other pictures appear in what are known as broken or rotten lines. Although these lines are comparatively so coarse, Prof. Houston ventures to express the opinion that with more carefully-prepared apparatus Mr. Delany will be able to transmit portraits and other work of the kind equal in fineness to an ordinary woodcut; he says, in fact, that he has no doubt it can be done with more carefully-prepared apparatus; but as no details of the process are at present available, it would be well to await further particulars before pronouncing an opinion one way or the other. The system has the great advantage that it is available for telegraphing in all languages, for it is as easy to produce Chinese characters as the simple Roman letters; but it is quite another thing to telegraph a portrait with all the fineness of even an ordinary woodcut, and we are afraid that it will be a long time before fac-simile telegraphing will reach that degree of perfection. As a sketch, however, no matter how crude, often conveys by a few lines much more than hundreds of words, it is evident that any really practical method of transmitting telegraph messages in fac-simile will find a wide sphere of usefulness. So much has already been done in that connection, especially in reproducing handwriting, that the early discovery of some comparatively easy method of transmitting lines and dots in absolutely accurate fac-simile may be confidently anticipated; but not a few rather more enthusiastic believers in progress firmly hold to the idea that what is known as tele-photography will be accomplished before the end of the present century. Some of our readers will no doubt remember that in Vol. XXXIII. pp. 158, 180, we gave an account of some experiments with what is called the selenium cell, which possesses the peculiar property of enormously varying its electrical resistance under the influence of light, and just as Graham Bell anticipates much in the future from the photophone, so others see in this remarkable property of selenium a possible means of transmitting photographs by telegraph. At the last meeting of the American Association for the Advancement of Science, Mr. C. E. Fritts described an improved method of making selenium cells, and hinted at, rather than suggested, their employment in several branches of electrical science. Some of these cells have been placed in the hands of Professor Grylls Adams, Dr. Werner Siemens, and Dr. G. F. Barker, and we may shortly expect to hear more about them. In the selenium cells which have been previously brought under the notice of the scientific public, the two parts of the selenium, at which the current enters and leaves the cell, have been in substantially the same electrical condition; the paths of the current and of the light have been transverse to each other, so that the two forces have partially neutralised each other in their action upon the selenium. In Mr. Fritts's form of cell we find a radical departure from former methods of employing selenium, for he uses very thin plates, and polarises them, so that the opposite faces have different electrical properties. That is done by melting the selenium upon a plate of metal with which it will form a chemical combination sufficient, at least, to cause the selenium to adhere and give a good electrical contact. To assist in effecting this object, the selenium, during the progress of melting and crystallising, is compressed between its metal plate and another plate, of steel or other substance with which it does not combine, and thus is formed a sheet of granular selenium, uniformly polarised throughout, and having its two surfaces in opposite phases as regards molecular arrangement. The non-adherent plate being removed after the selenium has cooled, the surface of the latter is covered with a transparent conductor of electricity, such as a thin film of gold leaf, platinum, or silver, and the advantage of this arrangement consists in the fact that it enables one to apply the current and the light to the selenium in the same plane or general direction, instead of transversely, so that both influences can be brought into similar action, or can be made to oppose each other, according to the effect desired. Previous to the experiments of Mr. Fritts, the most sensitive selenium cell was one made by Dr. Werner Siemens, which was about 15 times as conductive in the sunlight as in the dark; but by the new system devised by Mr. Fritts, selenium cells have been made which exhibit the extraordinary difference in resistance between light and dark expressed by the term "337·5 times," or under the joint influence of light and electricity, more than 99 per cent. of the resistance disappears temporarily. All the cells made by Mr. Fritts do not exhibit so remarkable a difference as that, but they are all vastly superior to anything hitherto achieved. He finds that to obtain these maximum results it is necessary to protect the cells from light when not in use, and to send the current in at the gold-plated face, for when the current and the light both act through the gold in conjunction, their forces are united, and every atom of the selenium being affected by the light, the full effect is obtained. The cells improve by use, but should be kept cool; and it is curious that the kind of battery employed has a remarkable effect upon the sensitiveness of the cells. For instance, cells which had their sensitiveness largely reduced when the bichromate battery is employed, became extremely sensitive with the Leclanché—a simple fact which suggests the truly scientific thought that if one battery current destroys sensitiveness, another may increase it. Hitherto Mr. Fritts has found no better battery than the Leclanché, but selenium exhibits some very peculiar properties in this respect, which will require the careful attention of the investigator. Mr. Fritts divides his cells into two classes—the L B. cell, in which the resistance becomes greater as the battery power increases—that is, "Like the Battery power," and the U.B. cell, one in which the resistance becomes greater as the strength of current decreases—that is "Unlike the

Battery power." These changes are not due to heating of the conductor or of the selenium, but appear to be caused by some peculiar property of the selenium, for the cells when first made have two states or conditions—very low and very high resistance. When very low Mr. Fritts has stimulated them by sending intermittent or alternating currents through them, and has made them become very sensitive to light; but some cells have been laid aside as intractable, because, although it was possible to stimulate them into a high degree of sensitiveness, they would not stop there, but dropped into the insensitive state. Hundreds of cells were thrown aside as worthless until Mr. Fritts became acquainted with this dual state, as he calls it; but now he expects to utilise them all for some purpose or another. The most peculiar point in this connection is the very wide range of resistance of the cells in the two states; in the low state it may be a few ohms or a few hundredths of an ohm, in the high state it is sometimes millions of ohms, and the change is effected instantly—a very interesting problem both for the electrician and the physicist. These selenium cells can be used as current generators, as they form a photo-electric dry couple or battery, but should be protected from overheating by the alum-water cell or other means. The current is then constant and of considerable E.M.F., and the cells can be arranged in series or in multiple arc as with any other battery. The current appears directly light is thrown upon the cells, and ceases as quickly when the light is shut off, the strength varying with the amount of light and the extent of surface lighted,—the intensity of the light being of no apparent importance in producing the change, though it undoubtedly has some effect on the intensity of action of the cell. It is curious, too, that the power of producing current is independent of the sensitiveness of the selenium cells to light, for, according to Mr. Fritts, some of his best current generating cells are only moderately sensitive to light, and some of the most sensitive will generate scarcely any current at all; but it is remarkable that the cells exhibit a constant resistance in sunlight for months, allowing for differences in temperature, &c. The sensitiveness to light is increased by what is called "proper usage," and that is shown not by a lowered resistance under the influence of light, but by an increased resistance in the dark. "Proper usage," however, is, in this connection, an undefined phrase, for so little is really known about these selenium cells that even Mr. Fritts himself cannot undertake to explain all the phenomena he has witnessed. He has, however, drawn attention in a very practical way to the amazing peculiarities of selenium cells, and has set on foot investigations which may prove extraordinarily prolific in inventions, for we have said enough to show that here we have a practically unworked field of investigation, which, in one direction, promises to yield all we need towards perfecting a system of fac-simile telegraphy.

## IMPROVEMENTS IN THE MANUFACTURE OF SODIUM.

ONE of the latest, if not the last, of the patents taken out by Mr. Sidney Gilchrist Thomas —whose untimely death was recently announced —was in connection with the manufacture of sodium, and, like all his inventions, it is of a promising nature. The reduction of sodium from carbonate of soda is at present effected by heating the latter with carbon in small wrought-iron retorts heated externally. These retorts are very rapidly destroyed, and their renewal is very costly, while the heating of the mixture is inefficient. Instead of these externally-heated retorts, Mr. Thomas placed the mixture of carbonate of soda and carbon in a retort or tube which may be of wrought or even cast-iron, lined with a thick lining of highly-fired magnesia or lime, or fritted dolomite, or other refractory material unacted upon by sodium, such as carbon or graphite. Instead of firing these retorts externally, he heated the mixture by passing into the interior of the tube reducing gases free, or as free as possible, from oxygen or carbonic acid, water-gas prepared from coke being preferred. These gases are first heated to a very high temperature by passing through regenerative stoves, preferably of firebrick, such as those of Siemens or Cowper, but on a small scale, which have been intensely heated by burning in them water gas or other gases. A sufficient number and area of regenerative chambers is provided to enable a steady temperature to be maintained by their alternate use. In this way the reduction of the sodium is more completely effected, and the cost of the retorts very greatly reduced. The operation may be rendered almost continuous by constantly introducing fresh quantities of sodic carbonate and carbon into the retort by means of a closed hopper. The tubes or retorts are, of course, of much larger diameter than those now employed. The reducing gases, which will consist chiefly of hydrogen or carbonic oxide, are subjected, after passing through the retorts, to rapid cooling, by passing through an artificially-cooled condensing chamber, which may be cooled by the circulation of water in pipes or otherwise, and the sodium vapour which is carried over is there condensed. The gases must be either forced through the retorts by pressure or by an exhaust. Potassium may obviously be manufactured in a similar way.

## RECENT IMPROVEMENTS IN ELECTRIC BATTERIES.

AMONGST recent patents connected with batteries, it is noticeable that the "improvements" consist mostly in the arrangements of the elements, though in a few cases new or hitherto unused substances are employed, either as excitants or electrodes. We have made a few notes on these, and taking them in numerical order, we first notice an improved "primo-secondary battery" (1100) by G. G. André. In this the negative element consists of a wooden core with a bottom flange, on which is wrapped lead, either in sheet or wire. That is surrounded by highly-burnt coke, in the granular form, mixed with peroxide of lead, and the whole inclosed in a porous envelope, such as two thicknesses of canvas, which may be nitrated to make it acid-proof. The positive element is either zinc, iron, or lead. The idea is that when the peroxide has been reduced to protoxide, the negative elements can be removed, taken to the charging-station, and there have the protoxide reconverted into peroxide by the current from a dynamo. The exciting liquid may also be taken to the station, when a sufficient quantity has been obtained, and have the zinc it holds in solution deposited by the same charging current. The improvements patented by Mr. Lyte (1278) also refer to a lead cell. At the bottom of a glass jar he places a box of sheet lead or antimonial lead about one inch in depth, and containing peroxide of lead. This is the negative element. To this box is attached a thick wire of lead, insulated from the positive element by means of an indiarubber or guttapercha tube, and extending from the box (to the exterior of which it is fastened) nearly to the top of the jar. The positive element consists of a thick zinc wire coiled in the form of a flat spiral. The positive element passes up through a cover with which the jar is provided, being enveloped where it passes through the cover with a short length of indiarubber tubing for insulation, and provided with a terminal above the cover. A wire from the negative element also passes through a hole in the cover and forms the other terminal.

Mr. Tribe (2078) patents the use of nitro-cellulose in the construction of containers, receptacles, frames or supports, for the active elements of batteries. Messrs. Lundy and Bottomley (2234) patent the use of chlorides of magnesium and manganese as excitants. The chlorides hitherto employed — ammonium, potassium, silver, sodium, and zinc—act prejudicially on the electrodes and other parts of the battery; but owing to the deliquescent properties of the chlorides of magnesium and manganese, they can be employed as excitants with beneficial results. Another feature of this invention consists in using either chloride of magnesium or chloride of manganese, or both, in combination with each other, or with chloride of zinc in solution, or in combination with any other compatible chloride or chlorides; or in solution with any compatible salt or salts, such as sulphate of sodium, sulphate of magnesium, or sulphate of potassium.

Improvements in the construction and working appliances of batteries have been patented by Mr. Emmens and the United Patents Corporation (2750), and consist of the employment preferably of cells of a rectangular form, in each of which is placed one or more porous pots, resting either on the bottom of the cell or on one or more chocks, so as to admit of free circulation of the outer fluid. The porous pots are covered by lids with sides sufficiently deep to form a water seal in the outer fluid when the cell is charged, and thus they prevent the escape of noxious fumes when a fume-emitting-dehydrogenising fluid is used in the porous pots. The inventors furthermore provide the lids with discharge tubes or nozzles for causing the fumes to pass off in any required direction. The tops of the lids are extended lengthwise so as to rest in notches made in the sides of the containing cells. The negative electrodes consist of plates of carbon or other suitable material, and they or their poles are carried through the lids. The positive electrodes consist of plates of zinc or other suitable material, and are provided with hooks or clips which hang on strips of metal affixed to the sides of the lids, and in electrical connection with each other. The positive terminals are made in the shape of small cups, which are partly filled with mercury or amalgam, and the connections between the different cells of a battery are effected by means of spring clips of brass attached to copper strips carrying a projecting stud at the other end, the clips being pressed down over the hooks of the positive electrodes, and the stud dipping into the cups of the positive terminals. Excellent contact is thus secured, and can be made or broken without the trouble of screwing and unscrewing nuts.

The next is one that has already been briefly noticed, and is entitled a "new electric couple" by the patentee, Dr. Prizbram (3,770). In an impermeable vessel, such as a glass jar, he places two cells concentrically one within the other. These cells are to be made of a material which is little liable to corrosion by acids or alkalies, and is possessed of a restrained permeability. There are thus two outer ring-shaped chambers and an inner or central cylindrical chamber. The outermost ring chamber contains an alkaline solution of any desired density or concentration, and also the electrode or electrodes, by the immersion of which electricity is generated—preferably a plate of zinc conveniently bent to fit the chamber, and carrying the negative terminal. The intermediate annular chamber is filled with water, which may be slightly acidulated, or a small quantity of alkaline solution (soda or potash) may be added to the same: but these additions are not indispensable. The central cylindrical chamber contains nitric acid, or any other compound which is rich in oxygen and easily parts with a part thereof, and the other electrode destined to gather the electricity generated; it is preferably made of carbon, and carries the positive terminal. Thermo-electric piles do not appear to attract much attention from patentees, for we have been able to find one only, and that from Vienna. It has been patented on behalf of Messrs. Lautemack, Kolm, and Laske (4158), and consists in giving to the electrodes a well-insulated core of elastic metal, which may either be the negative electrode or a neutral metal. Graphite is used preferably, to form the insulating layer, but clay, porcelain, glass, or asbestos may be used. If the core is the negative electrode, it runs through the whole length of the positive metal, and has a pole wire cast on one end, while the other end of both metals carries a piece of neutral plate, which is to be heated. If the core is formed of a neutral metal it may be wholly inclosed in the positive electrode, and the negative electrode will then act as heat receiver. We are afraid there is not much to hope for from the thermo-electric piles. In an improved secondary battery, patented by E. Jones (6068) each electrode in a pair is a counterpart of the other, and each is formed entirely of metallic lead so disposed as to present a very large extent of surface to the action of the exciting fluid in the battery. This large surface of metallic lead is obtained by forming the electrode with a number of strips, ribbons, or wires of metallic lead, arranged in rows and in-

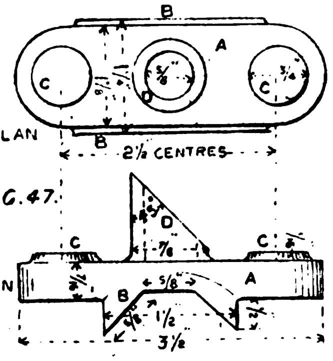

FIG. 47.

tegrally united with a base or wall of similar material, and preferably at right angles thereto. The two electrodes for every pair have their projecting strips, ribbons, or wires, so arranged that when in their proper relative position, the bases or walls will be opposite and parallel, the one with the other, and the rows of strips, ribbons, or wires projecting from one plate or base will interlock or alternate with those on the other plate or base, and will leave room for the insertion between them of insulating plates of glass or other suitable material.

C. Baudel patents improvements in batteries, in which the circulation of the exciting liquid is the chief feature. The battery is composed of any number of superposed elements of, say, zinc and carbon, separated by indiarubber of sufficient thickness to form a kind of chamber containing the exciting liquid. The latter flows into the outer vessel by gravity, and passing upwards through each "chamber" by means of holes in the plates, is drawn off at the top. The arrangement constitutes the invention (12374). In another patent (14476) the novelty consists in the employment of the different materials. It is the invention of J. Cerfaux, of Brussels. The materials are said to form a new combination: they are mercury, sulphate of copper, peroxide of manganese in grains, sulphate of zinc, peroxide of manganese, granulated and in powder, with crushed carbon from retorts, the whole covered with a layer of lead. Another part of the novelty of the invention also consists in the employment of a long lead wire inside the porous pot, formed into a spiral at the bottom of the pot, and successively traversing all the above-named materials downwards and upwards. This lead wire thus forms two rods stopping level with the porous pot, and it holds "magnetically" the different materials contained in the porous pot. So far as our search has extended through the patents of 1884, we cannot say that we have found anything very promising in the way of new batteries.

## ENGINE-MAKING AT HOME.—IV.

### The Flywheel and Bearings.

I ALLUDED in my first article to the difficulty of setting out a small engine by the rules applicable to those of larger dimensions apart from the assistance to be derived from the trained eye accustomed to note and apportion due relations of parts. The flywheel now furnishes a case in point. If we take one of the best-known rules for the weight of a flywheel rim, viz.:—

$$W = \frac{P S}{45 D}$$

Where—

W = weight of rim in cwts.
D = mean diameter of rim in feet.
P = total average pressure on piston in lbs.
S = stroke in feet

We shall find that our rim comes out at 1ft. 9in. mean diameter and 33·8lb. average pressure:—

$$\frac{33 \cdot 8 \times 8 \cdot 2 \ (= \text{piston area}) \times \cdot 502 = \text{stroke}}{45 \times 1 \cdot 75} = 201\text{lb.}$$

While with an average pressure of 48·3lb. we get—

$$\frac{48 \cdot 3 \times 8 \cdot 2 \times \cdot 502}{45 \times 1 \cdot 75} = 280\text{lb.}$$

These are excessive weights for so small an engine. Further, this rule takes no account of the rate of piston speed, which should have an important bearing on our conclusions, since a slow-running engine would require a greater reserve of power than a quick-running one; neither does it take account of the work to be done, whether intermittent or otherwise, really the most important consideration of all.* And if we take another rule which does embody the rate of speed:

$$W = \frac{\cdot 6366 \, P S C}{D} \left( \frac{N}{60} \right)$$

where—

P = pressure on piston in tons.
S = stroke of engine in feet.
D = mean diameter of rim in feet.
N = number of revolutions per minute.
C = constant = four for ordinary engines.
W = weight of flywheel rim in tons.

And assume a piston speed of 220ft., or = 10 revs. per minute, and a pressure as before o 33·8lb., we get 340·9lb. in our rim.

Under these circumstances the best way is to consider what kind of work the engine will be required to perform, and to proportion the wheel accordingly. I have drawn a wheel, Fig. 41, which I consider of good proportions for an engine doing variable work. The weight of its rim is 84¼lb. Arms and boss bring the weight of the casting up to 102lb.; but the weight of the rim alone is taken into account, since the arms do not materially influence the momentum. In a very light engine the weight might be reduced with advantage, either by diminishing the diameter to 16in. or 18in., and maintaining the same section, or by retaining the diameter, and reducing the metal. For driving purposes the width of the rim might be increased on the outer face, the inner metal being lessened, as shown Fig. 45.

---

* The mechanical energy stored up in a flywheel can be properly calculated only in relation to the precise nature of the work of the engine. The amount of work produced by a single half-stroke is estimated, together with the limits of variation in the quantities of power absorbed by the machinery driven thereby, and the weight of the flywheel is so calculated that its *vis viva* shall equalise those variations, so that the factors necessary for an exact estimate are the piston speed, the average pressure, the stroke, the variation from the mean velocity, the force of gravity, and the friction of the axle. The power stored up in the rim is made to exceed that which is given out by one half-stroke of the engine by from three or four to six times, according to circumstances. For a clear statement of the theory of the flywheel, together with formula based thereon, and appropriate examples in calculation, see Baker's "Mathematical Theory of the Steam Engine," published by Crosby Lockwood, pp. 37—41, in the 7th edition.

This is a small fly-wheel, hence no moulder would care about the trouble of making it in cores—the method adopted in large fly-wheels, neither should we like to see so small a wheel with wrought-iron arms. So we go in for a pattern, and decide on arms having an oval section, as being more elegant in appearance than those of rectangular form.

There is no way of making a pattern of this kind strong enough for moulder's usage, except by building it up in segments, Fig. 42. The ends of these segments are plumb one over the other in their alternate layers like the joints in masonry, and a ring built up thus is stronger than if made in any other way. The greater the number of thicknesses used in building up, the stronger the pattern, but the courses need not all be of the same thickness, so that their number and thickness may depend upon what stuff we happen to have by us. If we have to buy, we shall purchase stuff that will plane up to $\frac{7}{16}$in. thick; $\frac{1}{2}$in. board will do this, if a thick board be selected. This will make a strong ring in five courses.

But, again, if we make the arms simply to drop within the ring, we have a very weak mode of attachment indeed, and short grain besides in the hollows. Hence we determine to fit the arms to some little distance into the rim. This must be done, however, while the rim is yet partly built up, so that we want to determine on a certain thickness of stuff out of which the hollows are to be cut, such thickness to bear reference to the segmental thicknesses. If we have, as we suppose, five sets of segments—these divided between $2\frac{3}{16}$in. thickness will finish to $\frac{7}{16}$in.—then we settle that our arm stuff shall be $\frac{7}{16}$in. × 3 = $1\frac{6}{16}$in. thick, which will leave one clear segment on each side. So we proceed in this way:—

For five sets of segments, saw out, at six to the circle, 30 segments about $\frac{3}{8}$in. wider than the finished width, and $\frac{1}{2}$in. longer than the sixth part of the circle. Level a wooden face chuck, and glue one ring of segments upon it, with slips of paper intervening, but extending only about an inch to each side of the end joints of the segments. These paper slips are to permit of ready detachment of the ring from the plate after it is turned, the paper parting in two readily without splintering the wood. Upon this first set glue three others in succession, facing the surface of each set in the lathe after the glue has dried, and chalking over the surface so obtained for the proper fitting of the segments in the set to come next above. When the fourth course is glued on leave it for awhile while the arms are being prepared.

Get out three pieces of stuff $20\frac{3}{4}$in. by $2\frac{1}{4}$in. by $\frac{7}{8}$in., all finished sizes, and lock together with joints, as shown in Fig. 43. The views are self-explanatory, and the thickness of each middle web is one-third of $\frac{7}{8}$in., and the angles of the rebated edges are at 60° with the edges of the stuff. Put together temporarily, mark a 5in. circle in the middle, and from that 5in. circle, working from both sides of the stuff, bevel each arm-piece to $\frac{3}{4}$in. thick at the ends. The $\frac{7}{8}$in. and $\frac{3}{4}$in. thicknesses represent the conjugate diameters of the elliptical sections next the boss and the rim respectively. To make up the ends to the $1\frac{6}{16}$in. thickness necessary for letting in to the rim, we must glue a slip of wood on each face $2\frac{1}{4}$ by about 2in. by $\frac{9}{32}$. Now mark the shape of the arms, Fig. 41, plan, on the stuff so prepared, take apart and work to shape, cutting the edges square in the first place, afterwards cutting the elliptical forms at each end respectively (Fig 44), using a chisel and templets, and working the intermediate portion straight along with a small thumb-plane and bull-nose. Glue the arms together finally, and complete then the $\frac{3}{4}$in. hollows around the central boss.

Returning to the ring, which has dried in the interval, turn the inner portion to 1ft. $6\frac{1}{2}$in. diameter, Fig. 41, and laying the arms centrally upon the face, scribe around their ends, and cut down six recesses to those lines $1\frac{5}{16}$in. deep. Into these recesses glue and screw the arms finally, Fig. 42, and over them glue the last course of segments, one only of the final course being shown in the figure. Then turn the outside of the wheel, and also the inner edge of the course last glued on, and remove from the face-plate. The radii of the arms next the rim are then completed with gouge and penknife. All that now remains is to turn two bosses with hollows as shown in Fig. 41, and to screw them upon each side of the arms. One boss has to receive a print on its centre, $\frac{7}{8}$in. in diameter.

The bearing block for the crank shaft is shown in Fig. 46, its cap in Fig. 47, and the brass in Fig. 48, and all dimensions are given therein. I have given the diameter of the shaft as $1\frac{1}{8}$in., which is $\frac{1}{8}$in. over the size given by the rule which makes the shaft = the bore of the cylinder × ·33. The pattern, of course, has boring allowance. No portions are left loose for moulding. The block moulds with its flat faces up and down as it lies on the sheet. The cap moulds with oil cup downwards, and the brass with its hollow working face down. But they are so small that enough taper for moulding may be given by glass-papering.

The bearing block is made in six pieces: the foot A, the block B; two facings. C C, for the shoulders of the brasses; and two bosses, D D, for the hold-down bolts. All are glued and bradded together simply, and the hole is cut out in the pattern for the reception of the brass.

The cap is made in four pieces, consisting of the plate A, out of which the portion which clips the brass is cut; the facing B B for the shoulders of the brasses, the bosses C C for the tightening bolts, and the oil cup D. The latter is glued upon a face-plate with a paper joint, turned and bored, cut to the angle of 45°, removed and glued in position. An oil-cap cover, Fig. 49, is also made.

The brass, Fig. 48, consists of three pieces, the centre, A, being squared to $1\frac{1}{4}$in., and cut to fit tightly into the bearing block. If so fitted, it will come out a trifle larger in the casting, so that a little easing with the file will make it fit without much labour.

The flanges B B are turned, and fastened to the central block, and the 1in. semicircular hole worked through.

Brasses are now commonly fitted by turning, as being cheaper than filing; and a stud, Fig. 50, prevents them from slipping with the revolution of the shaft. But the old-fashioned way is easier in this instance.

## LOCOMOTIVES ON THE BRIGHTON LINE.

THE following is the substance of a paper read by Mr. W. Stroudley, M.Inst.C E., at a recent meeting of the Institution of Civil Engineers. It will be seen that it refers to several very important points, but it may be stated that the figures referring to evaporation and coal consumption require verification because they are so exceptional.

The author, on his appointment to the London, Brighton, and South Coast Railway, in 1870, had to consider what kind of locomotive engine and rolling stock would best meet the requirements of the service; as, owing to the great increase and complication of the lines and traffic, the original primitive engines and rolling stock were not able to do so. He, therefore, in the same year, designed a large goods engine, class "C," arranging the details so that they would enable him to construct the several classes illustrated, all the principal parts being interchangeable. Having had long experience with both outside and inside-cylinder engines, he adopted inside cylinders, but placed the crank pins for the outside rods on the same side of the axle as the inside crank, the outside pin, however, having a shorter stroke; and he thus obtained the advantages of both systems. He adopted the method of putting the coupled wheels in front, instead of at the back as usual, which permitted the use of small trailing wheels, lightly weighted, and a short outside-coupling rod for the fast running engines, and also a much larger boiler than could be obtained when the coupled wheels were at the back. The author adopted a somewhat high centre of gravity, believing that it made the engine travel more easily upon the road, and more safely at high speeds; the slight rolling motion, caused by the irregularities of the road, having a much less disturbing influence than the violent lateral oscillation peculiar to engines with a low centre of gravity. The high centre of gravity also threw the greatest weight upon the outside or guiding wheel when passing round curves; and this relieved the inner wheels, and enabled them to slip readily. The author used six wheels in preference to a bogie for these engines, to avoid complication and unnecessary weight. The engines were very light for their power. Spiral springs were used for the middle axle, and these had a greater range than the end ones for the same weight. The two cylinders of the large engines were cast in one piece, with the valves placed below, giving lightness, closeness of centres, and easy exhaust and steam passages. The crank axle was the only disadvantage left in an inside cylinder, inside framed engine, and, when this was of good proportions, it offered but a small objection. Owing, however, to the narrow gauge of the rails in this country, the crank axle could not be made so strong as it ought to be, or there would be no reason why a crank axle should break. When the flanges of the driving wheels were turned down thin, so as to avoid the side shock given by crossings and check-rails, there only remained the strain of the steam upon the pistons to cause breakage; the action of this was precisely the same as the methods used by the late Sir William Fairbairn in testing to destruction the model tube for the Menai Bridge, by letting a heavy weight rest upon it suddenly at frequent intervals. The deflection, if sufficient, caused a crack at the weakest place, which gradually extended until fracture took place. This was precisely what occurred in the axle; the crack invariably commencing on the side of the axle opposite to that to which the steam was applied.

The author, after thirty years' experience, believed that the separate parts of locomotives, including tires, axles, piston-rods, side-rods, bolts, cotters, and carriage and wagon axles, broke from the same cause; they did not break when carefully designed and made with proper materials and workmanship. As the crank axle could not be made of the proper strength, it was well to consider how to avoid, as far as possible, risk of accident by its failure. By making the axle-boxes and horn blocks deep and strong, giving large flat surfaces against the boss of the wheel and the outside of the crank arm the driving-wheel was kept in position after the axle was broken, if the fracture occurred in the usual place—namely, through the inside web, near the crank pin, or through the centre part where it joined the inside web. An axle broken in this manner would run safely over any part of the road, except at a through crossing, where the guiding-rail was lost, and the flange was liable to take the wrong side of the next point; this, however, had not happened in the author's experience. The author had always hooped the larger cranks, and had for some time hooped every new crank in the same proportion as adopted on the Great Northern Railway, thus reducing the risk to a minimum. The engines had been arranged that part of the exhaust steam might be turned into the tender or tanks, so that the feed-water might be heated. This was a special advantage in a tank engine, by increasing the total quantity of water; it also kept the water supply of greater purity, and it relieved the boiler of a certain amount of duty in heating the water from the ordinary temperature to that which feed-water required. The feed-pumps had been designed to meet the requirements of pumping hot feed-water. The proportions of the valve-gear gave an admission of 78 per cent. of steam in full gear, which could be reduced to 12 per cent. with excellent results; and as at high speeds the steam was never exhausted, the temperature of the cylinder was maintained and as much steam was locked up in the cylinders as raised the pressure at the end of the stroke to near that in the steam chest. This made the engine run very smoothly at high speeds, and turned what would otherwise be an extravagant coal burner into an economical machine. And for the same reason the compounding of fast passenger or frequent-stopping locomotives was not likely to show much, if any, economy over a well-designed simple engine. The case was different, however, in heavy goods engines, working with a late cut-off most of the time, and where the conditions approximated closely to those of a land or marine engine with a constant load. The back pressure observed in the diagrams of high speed locomotives was not therefore a defect, but an advantage, and the author accordingly used small steamports and short travel of slide-valve. These remarks as to back pressure did not apply to the pressure in the exhaust pipes, where it should be as small as possible, but only to the back pressure in the cylinder. The latter was greatest at high speeds, when a small volume of steam was passing through the cylinders, and small power was required, and least when working full power with the smallest expansion. All the passenger engines and many of the goods engines were fitted with the Westinghouse automatic air-brake, as were also the whole of the carriages. This brake gave entire satisfaction, and complete control of the trains. The author took considerable pains with the fittings and details when it was first introduced, and arranged the gear for the engines, so that the brake acted upon each wheel independently, allowing the springs freedom to act; or it acted upon the front of all the wheels, as in the tank engines, the brake of which was moved by hand as well as by the air pressure. The Westinghouse air-pump had been fitted with a plunger at the bottom end of the rod, $1\frac{3}{4}$in. in diameter, and this pumped water into the boilers of the goods engines when they were in sidings or were delayed by signals. For the express and large goods engines, the greatest possible amount of heating surface had been provided: the fire-box was capacious, with small tubes of considerable length in proportion to their diameter, little or no flame being generated with the coal used, and a very small amount of soot. The fuel which was found cheapest to consume in this locality was smokeless coal from South Wales, mixed with a small quantity of bituminous coal from Derbyshire. The boilers were made of the best Yorkshire iron with plates having planed edges: holes were drilled after the plates had been bent; the joints were butt-joints, and they were hand riveted. The construction of the ash-pan and its dampers, perforated plates, water-supply, and the arrangement of fire-bars, brick arch, fire-door, and deflector, was shown. The indicator diagrams, taken by one of the Crosby Steam-Gauge and Valve Company's indicators, at various speeds, and under varying conditions of gradient, afforded a fair idea of the working capabilities of these engines, the economical value of which was best shown by quoting the consumption of fuel for the half-year ending the 30th of June, 1884, when the average of the whole of the engines on this line was 29·74lb. per engine mile, including the coal used in raising steam. A great number of careful tests had been made of the amount of coal required to raise steam in the engines from cold water, and also from the partially heated water when the boiler had not been emptied, and this amounted on an average to about 3lb. per mile run. Some doubt had been expressed as to the value of heating feed-water by the exhaust steam. The author, therefore, had a number of tests made with the ordinary heating apparatus removed, and water fed to the boilers by the feed pumps, and in one series by a Borland's injector. The amount of power required to work the pumps was inappreciable; and the heated feed-water brought about reduction in the consumption of fuel to the extent of over 2¼lb. per train mile. It had also been found that heating the feed-water by direct contact of the steam did not, on this railway, injuriously affect the boiler plates. With a view to ascertain what was the amount of power required to haul a train from Brighton to London, a complete set of 49 diagrams was taken from the engine "Gladstone" working an express train of twenty-three vehicles, the total weight of train and engine being 335 tons 14 cwt. A section of the line was given, and clearly illustrated the result, giving the horse-power at about every mile, the speed, and the gradient. The temperature of the gases in the smoke-box was taken at frequent intervals; also the degree of vacuum in the fire-box and in the smoke-box, and the quantity of water used out of the tender. To the latter had to be added the water condensed from the exhaust, which from experiments the author estimated at 20 per cent. This gave an evaporation of 12·95lb. of water per 1lb. of coal, and 1lb. of coal would convey one ton weight of the train 13½ miles, at an average speed of 43·38 miles per hour over the Brighton Railway, the rate of consumption being 2·03lb. of coal per horse-power per hour.

## DR. KLEIN ON CHOLERA.

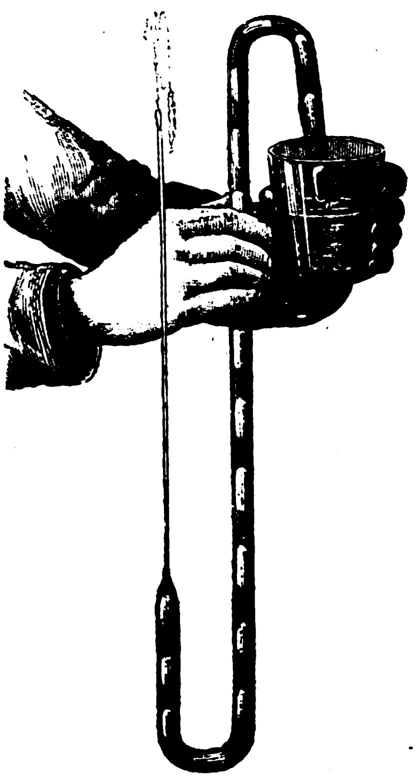
At a recent meeting of the Abernethian Society of St. Bartholomew's Hospital, Dr. Klein briefly reviewed the accepted theories as to the ætiology of cholera, and stated the views concerning it which he had been led to adopt since his visit to India. His speech is of importance as embodying the conclusions of the Indian Commission of Inquiry into this disease. Two main theories are held with regard to cholera—the one, supported by a large section of the Indian medical staff, being that cholera is non-infectious and non-communicable; the other, upheld by European authorities, that it is both infectious and communicable. In support of the former theory may be quoted the numerous cases of sporadic cholera which occur, and the fact that when troops are attacked in a military cantonment and are at once marched out into camp no new cases occur other than those which are already incubating. Lastly, in many places in India, in spite of all conditions favourable to the spread of the disease by choleraic evacuations, as a rule only sporadic cases occur. In support of its communicability and infectiousness it is unquestionable that when an outbreak of cholera has occurred it has in most instances been introduced from a district where cholera was rife, as instanced by the late outbreak at Marseilles, which was shown to have been introduced from Egypt. Some have maintained that it may be conveyed by winds; against this may be adduced the fact that epidemics have occurred in Malta without any occurring at the same time in Gozo. Now, Gozo is nearer to Egypt than Malta, and yet no epidemic at Malta has ever been preceded by an epidemic at Gozo. The upholders of the theory of infectiveness are divided into two schools—the contagionists, who consider that the disease is directly communicable from the sick to the healthy, and that the virus is contained in the discharges from the alimentary canal; and the localists, who believe that the evacuations contain a germ which is capable of elaborating the virus under suitable conditions of climate and soil. Against the contagionists' view must be considered especially these facts—that it is very rare for attendants to be attacked early, and that they only succumb at a late period of the epidemic, and that cholera patients are treated in the general wards of a large hospital in Calcutta, and yet no cases of contagion have occurred. Dr. Koch, in studying this disease, found that the lower part of the small intestine of patients who died from cholera swarmed with peculiar bacilli (comma bacilli), which passed out with the evacuations, and which he considered were capable of manufacturing the cholera virus when introduced into the small intestine of an unhealthy patient. He also believes that this bacillus is destroyed by the acid secretion of the stomach of a healthy person, and, further, that this bacillus is destroyed by drying; and hence that this disease could not be propagated by soiled linen after this had been dried. The German Commission believes these bacilli to be the cause of the disease. Dr. Klein, by a series of experiments, has proved that these comma bacilli are not destroyed by an acid solution of the same strength as that of the gastric juice: but that, on the contrary, they thrive after having been immersed in such a solution. Further, that though these bacilli, in common with all germs (except spores of bacilli), are destroyed by thorough and scientific drying, still soiled linen never becomes thoroughly dry. Klein thinks that even the location of these bacilli in the lower part of the small intestine should not of itself suggest suspicion, inasmuch as bacilli and micrococci in great numbers are contained in it even in health, and the more because this locality is not the exclusive seat of the disease. More conclusive evidence, however, was collected by him in India. For instance, three of the houses situate in a fashionable street in Calcutta contained in all eight cases of cholera. Leading out of the square was a narrow lane to a large water tank, around which was built a squalid rookery. The water of this tank was used in the rookery for all purposes, and contained the comma bacillus. Now, the houses in the square were not supplied with water from the tank, and yet eight cases of cholera occurred in the square, while none were found in the rookery, which was inhabited by about 200 families. The English Cholera Commission has also found a bacillus apparently identical with the comma bacillus in the intestines of children and adults suffering from diarrhœa. Dr. Lewis, of Netley, has found the same in the saliva of healthy persons. With regard to the evacuations containing the virus, Klein found that in India the public-built wells were universally contaminated by sewage, and that the water, though nominally not used for drinking purposes, for expediency was generally so used, and especially at night time. Again at Benares, a large sewer opens into the Ganges at a spot where the pilgrims and natives perform their religious ablutions, these including especially the washing out of the mouth with the river water. In spite of this, only sporadic cases of cholera occur. Dr. Klein has been led to the conclusion with regard to the cholera—that Koch's bacillus cannot be the cholera germ.

## THE OCHOROWICZ LOUD-SPEAKING TELEPHONE.

In this instrument, which is stated by M. Hospitalier, in *L'Electricien*, to be the most powerful he has heard, the inventor has sought to transmit to a distance speech, as well as vocal and instrumental music, with such clearness that an opera, for instance, may be heard by several people some distance from one another, and without having to bring the receiver to their ears. The system comprises a microphonic transmitter of new and special construction, and of a magnetic and receiving telephone, the magnet of which is a solid steel cylinder with a slot down the length of its surface 5 or 6mm. (1¼in.) wide, with two soft iron cores 3 or 4mm. in diameter about the middle, and carrying coils. The latter are inclosed in a kind of flat box, formed of two thin iron plates, one at the top opposite the cores (as in ordinary telephones) and the other at the bottom, screwed to the middle of the magnet. The lower plate is pierced with two holes of a larger diameter than the soft iron cores which traverse it, so as to move freely without touching, these two circular and parallel plates being connected together at their outer edges by a metal crown. In this way, the two plates are only fixed by a point, that which connects the lower plate with the magnet; they form a kind of vibrating box very mobile and elastic, which contains the coils. When the undulating current, modulated by the transmitter, passes through them, it modifies the flow of force inside, increasing or diminishing it. The box closed by the two plates contracts or expands under the influence of these variations of intensity, vibrating throughout its whole substance, thus accounting for the remarkable power of this telephone. It is also capable of acting as a magnetic transmitter, and permits of speaking and hearing in the same manner for a certain distance; but in this case the effect is considerably less marked than with the microphonic transmitter.

## EXPERIMENTS WITH THE SIPHON.

The following description of some interesting experiments with the siphon is sent by Prof. G. M. Clayberg, teacher of physics in the West Division High School, Chicago, to the *Scientific American*. Some very instructive experiments may be performed in the following manner:—Take a piece of ordinary glass tubing about 5mm. (·2in.) in internal diameter and one metre (39·4in.) long. Fifteen centimetres (6in.) from one end bend it to an angle of 100°, and 5 centimetres (2in.) farther to an angle of 90°. Draw out the other end to a point, and grind off the point so as to leave a hole about one millimetre (·04in.) in diameter. Twelve centimetres (4¾in.) from this end bend it twice at right angles in the same plane as the bend at the other end. Grind off the large end obliquely. When finished, the siphon will be as in the illustration. Place the large end in a vessel of water in which a little aniline red has been dissolved, and support the apparatus high enough so that the whole siphon can be seen by all the class. Start the water, and of course it will run. Lift the siphon so that the opening of the large end is partly out of the liquid, and you will have the beautiful appearance of a succession of spaces filled alternately with the coloured liquid and with air. The length of these spaces can easily be regulated by raising or lowering the siphon a very little. Again lift the siphon entirely out of the liquid until fifteen or twenty centimetres of air have entered, and then lower it into the liquid again. The long bubble of air will pass slowly down the long vertical part of the tube and then up the short and pointed arm until it reaches the small opening, when it will rush out with great velocity. The rapid escape of the air gives the liquid behind it great velocity, and when it reaches the small opening at the end of the tube it is suddenly checked, producing considerable pressure—pressure enough to throw a few drops of the liquid 10ft. or 15ft. high, easily seen when the drops strike the ceiling of the class-room. This sudden arrest of the velocity of the flowing liquid illustrates the principle of action of the hydraulic ram.



## DO PLANTS VARY WHEN PROPAGATED BY CUTTINGS?[*]

On reading what is said about "seed" potatoes in last week's *Press*, I notice the assertion is made that "seed" taken from the most productive hills gave a larger yield of tubers than that taken from the least productive. I am inclined to believe that further experimennts will show that this increased productiveness will not continue to hold, because the reason for the greater or less yield was probably only an accident of circumstances, especially favourable conditions of the set made to form the hill, or by being highly fertilised, or some such cause that gave it this temporary advantage; and that the chances are all against any permanent improvement being made by such selections. The potato is said to have been introduced into Europe in 1584. If the original tubers had had the highest cultivation that the skill of man could give, it is exceedingly doubtful if 300 years of culture would have changed them in the slightest degree if propagation had been solely from the tubers and not from seed proper. I base this opinion on a very extended experience in the cultivation of plants from cuttings. Strawberry plants taken from any well-known kind, such as Sharpless, for example, from strong, vigorous, growing plants will certainly give better results than from weak plants of the same kind, planted in the same soil. But if the progeny of the strong and the weak plants are again taken and replanted, the difference between the two would hardly be perceptible after they had been growing together under the same conditions. Every now and then we hear of varieties of fruits or flowers, said to be degenerating, that are propagated from cuttings, grafts, or roots. I believe there is no such thing as permanent degeneration of any fruit, flower, or vegetable that is raised from cuttings, grafts, or roots. The Jargonelle pear, the Ribston Pippin apple, the Hamburg grape, or the Keen's Seedling strawberry of the English gardens are found to look just as good, and as bad, under different conditions of culture as they were fifty or one hundred years ago, and that any change, either better or worse, is only an accident of circumstances, and temporary. For be it remembered that when a plant is raised from cuttings as in the grape vine, grafts as in a pear, or layers as in a strawberry, or pieces of the root as in a potato, such parts are not seed proper, but are merely parts of the same individual first called into existence. The Early Rose potato, introduced nearly a quarter of a century ago, is just as good to-day, under proper cultivation, as when first introduced, but is certainly no better. It is often to be found, of course, under unfavourable circumstances, and then may be supposed to have degenerated; but when it is shown under other circumstances to be as fine as when first introduced, how can the assertion of permanent degeneracy be admitted?

---

[*] By Peter Henderson, in the *Philadelphia Press*.

Permanent improvement, in my opinion, in varieties, can only be made by the selection of the fittest specimens that have been raised from seed proper. Here we have, as in the Early Rose potato, the Sharpless strawberry, and the Concord grape, varieties that have shot ahead of their fellows, having merits that the general public recognise, but all the art of man cannot further improve these so that their "progeny" (to use a convenient, though, perhaps, not a strictly correct term) will be permanently better or worse than when first called into existence. It is a very common error, when a luxuriant crop of anything is seen growing under specially good culture, to imagine that cuttings, roots, or seeds from such plants must necessarily give similar results when the same conditions to grow such crops well are not present. Not long ago Boston was famed for its rosebuds, and even experienced florists paid double price for stock from such plants, only to find that in their hands these plants would not produce Boston rosebuds. Now the case is changed. Madison, N.J., as a whole, beats Boston in rose culture, and the demand has changed from Boston to Madison, and, of course, with the same results; for, if the purchasers of Madison roses cannot give Madison culture, there will be no Madison rosebuds. While we admit the advantage of a healthy stock, and even, perhaps, the value of a change of stock, what I claim is that no culture will permanently change the variety from the normal condition, and that the only advance that can be made is by selecting the best specimens, hybridising these from their seed, again selecting, and so on forward. To be sure, we have in rare instances what are known as "sports" by gardeners, or what Darwin has called "bud variation," which may be improvements on the original variety or the reverse; but culture, good or bad, has nothing to do with such anomalous cases. Again and again we see it asserted as a matter for wonder that the wild celery of English marshes or the wild carrot of the hedge rows have attained their present high condition by "cultivation." If cultivation means that man has through generations "selected the fittest" of these again and again, taking always the flower of the flock, so as to have attained the present perfection, then that is true; but if by "cutivation" is meant that "domestication" by high culture, manuring, &c., in a garden or a field, has caused such results, then, in my humble opinion, it is not true.

# A NEW DEVELOPER CONTAINING SULPHITE OF AMMONIA, WITH A NOTE ON THE LIME DEVELOPER.*

I HAVE fully recognised the value of the potash developer for rapid plates and short exposures; but notwithstanding this, I now advocate a fresh developer containing ammonia and sulphite of ammonium, this developer having proved excellent with almost all kinds of commercial plates.

A.—Dissolve 10 parts of pyrogallol, and 25 to 30 parts of sulphite of ammonium, in 100 parts of water.

B.—Dissolve 5 parts of bromide of ammonium in 150 parts of water, and add 50 parts of liquid ammonia.

The working developer is made by mixing 100 cubic centimetres of water, 4c.cm. of the pyrogallic solution A, and 4c.cm. of the alkaline solution B. Development takes place very quickly, and if it is desired to make the reaction slower, more water (50c.cm. extra) is added. This leads to the production of softer pictures. If, on the other hand, more vigorous images are required, a few drops of a 10 per cent. solution of ammonium bromide must be added. The ammonium sulphite developer gives very well-modelled, brilliant negatives, in which the high-lights are well rendered, and the deep shadows are full of modelling, while the negatives have an agreeable dark-brownish tint. The ammonium sulphite makes the aqueous solution of pyrogallol more permanent than when the sodium sulphite is used, and there is but little liability to to fog with it. *A Developer with Lime Water.*—Pyrogallic acid and lime water were first recommended by Davanne for collodio-bromide emulsion, and this developer can also be used with gelatine emulsion plates. As lime is but slightly soluble in water, it is convenient to make a 10 per cent. solution of sugar in water, and to saturate this with slaked lime. The pyro-lime developer becomes violet and brown in use, also becomes turbid; while the developed images produced are so thin that I do not think very much of this developer.

# STAINING TISSUES FOR PHOTOGRAPHY.†

By George A. Piersol, M.D.

SATISFACTORY results in photographing histological tissues depend largely upon two conditions. 1. Having a section so thin and even that little more than a single layer of cells is included. 2. Having such thin section properly stained—especially sufficiently differentiated. Regarding the first condition, but little difficulty is experienced in these days of sliding microtomes, whose advent has marked a new era in section cutting. The successful completion of the second condition for photography is not always as readily accomplished. By most workers probably the stains ordinarily employed and valued for general use are borax-carmine and hematoxylin; of the two the latter is usually the more highly prized—the simple manipulations required and the unsurpassed results justly giving hematoxylin a recognised pre-eminence. These sections stained with borax-carmine (properly used) yield often excellent negatives; in their strata the red colour being sufficiently non-actinic to give a vigorous contrast on the plate. In well differentiated carmine staining, however, little else than cells is coloured, and frequently delicate details of the connective-tissues are wanting on account of their transparency. Hematoxylin stainings in very thin sections, while all that can be desired under the microscope, are usually very disappointing when photographed; the delicate layer of tissue offers almost no actinic contrast when monochromatic sunlight is obtained by the ammonio-sulphate of copper cell. Since hematoxylin is so extensively employed in all lines of work, a ready modification of this staining to meet the needs of photography is of advantage. While especially intended for nervous tissues the modified use furnishes specimens of all organs admirably adapted for photography. No especial formula for hematoxylin is needed, using one which is capable of staining deeply and giving standard results. In the usual course of work the sections are stained; a very few thin ones, however, are allowed to remain in the solution, after those for ordinary preparation, until they are of an intense dark purple, when they are transferred, one by one, to a capsule containing a solution composed of the following constituents:—

| | |
|---|---|
| Borax | 1·0 |
| Potassium ferricyanide | 2·5 |
| Water | 100·0 |

In this they are kept moving until the intense colour is gradually discharged, and the purple tint is replaced by a bronze-yellow, shading to saffron. Before the sections reach the latter colour they should be washed in water; the further usual steps in mounting are then completed. Sections so stained, and mounted in balsam, will be found to possess all the differentiation given by hematoxylin, with a change from the purplish blue colour to the subdued tones of brown—a substitution often most pleasing and grateful to the eye.

# CRITICAL METHODS OF DETECTING ERRORS IN PLANE SURFACES.

By John A. Brashear.*

FOR a number of years I have been practically interested in the subject of the production of plane and curved surfaces, particularly for optical purposes—*i.e.*, in the production of such surfaces, free if possible from all traces of error—and it will be pleasant to me if I shall be able to add to the interest of this association by giving you some of my own practical experience, and may I trust that it will be an incentive to all engaged in kindred work to do that work well. In the production of a perfectly plane surface there are many difficulties to contend with, and it will not be possible in the limits of this paper to discuss the methods of eliminating errors when found, but I must content myself with giving a description of various methods of detecting existing errors in the surfaces that are being worked, whether, for instance, it be an error of concavity, convexity, periodic or local error. A very excellent method was devised by the celebrated Ross, which is frequently used at the present time, and those eminent workers, the Clarks of Cambridge, use a modification of the Ross method which in their hands is productive of the very highest results. The device is very simple, consisting of a telescope in which the aberrations have been well corrected, so that the focal plane of the objective is as sharp as possible. This telescope is first directed to a distant object, preferably a celestial one, and focussed for parallel rays. The surface to be tested is now placed so that the reflected image of the same object, whatever it may be, can be observed by the same telescope. It is evident that if the surface be a true plane, its action upon the beam of light that comes from the object will be simply to change its direction, but not disturb or change it any other way, hence the reflected image of the object should be seen by the telescope without in any way changing the original focus. If, however, the supposed plane surface proves to be convex, the image will not be sharply defined in the telescope until the eyepiece is moved away from the object-glass, while if the converse is the case, and the supposed plane is concave, the eyepiece must now be moved towards the objective in order to obtain a sharp image, and the amount of convexity or concavity may be known by the change in the focal plane. If the surface has periodic or irregular errors, no sharp image can be obtained, no matter how much the eyepiece may be moved in or out. This test may be made still more delicate by using the observing telescope at as low an angle as possible, thereby bringing out with still greater effect any error that may exist in the surface under examination, and is the plan generally used by Alvan Clark and Sons. Another and very excellent method is that illustrated in Fig. 1, in which a second telescope, *b*, is introduced. In place of the eyepiece of this second telescope, a diaphragm is introduced, in which a number of small holes are drilled, as in Fig. 1, *x*, or a slit is cut similar to the slit used in a spectroscope, as shown at *y*, same figure. The telescope *a* is now focussed very accurately on a celestial or other very distant object, and the focus marked. The object-glass of the telescope *b* is now placed against and "square" with the object-glass of telescope *a*, and on looking through telescope *a* an image of the diaphragm with its holes or the slit is seen. This diaphragm must now be moved until a sharp image is seen in telescope *a*. The two telescopes are now mounted as in Fig. 1, and the plate to be tested placed in front of the two telescopes as at *c*. It is evident, as in the former case, that if the surface is a true plane the reflected image of the holes or slit thrown upon it by the telescope *b* will be seen sharply defined in the telescope *a*. If any error of convexity exists in the plate, the focal plane is disturbed and the eyepiece must be moved out. If the plate is concave it must be moved in to obtain a sharp image. Irregular errors in the plate or surface will produce a blurred or indistinct image, and, as in the first instance, no amount of focussing will help matters. These methods are both good, but are not satisfactory in the highest degree, and two or three important factors bar the way to the very best results. One is that the aberrations of the telescopes must be perfectly corrected, a very difficult matter of itself, and requiring the highest skill of the optician. Another, the fact that the human eye will accommodate itself to small distances when setting the focus of the observing telescope. I have frequently made experiments to find out how much this accommodation was in my own case and found it to amount to as much as 1-40th of an inch. This is, no doubt, partly the fault of the telescopes themselves, but, unless the eye is rigorously educated in this work, it is apt to accommodate itself to a small amount, and will invariably do so if there is a preconceived notion or bias in the direction of the accommodation. Talking with Prof. C. A. Young a few months since on this subject, he remarked that he noticed that the eye grew more exact in its demands as it grew older, in regard to the focal point. A third and very serious objection to the second method is caused by diffraction from the edges of the holes or the slit. Let me explain this briefly. When light falls upon a slit, such as we have here, it is turned out of its course; as the slit has two edges, and the light that falls on either side is deflected both right and left, the rays that cross from the right side of the slit towards the left, and from the left side of the slit towards the right, produce interference of the wave lengths, and when perfect interference occurs dark lines are seen. You can have a very pretty illustration of this by cutting a fine slit in a card and holding it several inches from the eye, when the dark lines caused by total extinction of the light by interference may be seen. If now you look towards the edge of a gas or lamp flame you will see a series of coloured bands that bring out the phenomenon of partial interference. This experiment shows the difficulty in obtaining a perfect focus of the holes or the slit in the diaphragm, as the interferences fringes are always more or less annoying. Notwithstanding these defects of the two systems I have mentioned, in the hands of the practical workmen they are productive of very good results, and very many excellent surfaces have been made by their use, and we are not justified in ignoring them, because they are the stepping stones to lead us on to better ones. In my early work, Dr. Draper suggested a very excellent plan for testing a flat surface, which I will briefly describe. It is a well-known truth that if an artificial star is placed in the exact centre of curvature of a truly spherical mirror, and an eyepiece be used to examine the image close beside the source of light, the star will be sharply defined and will bear very high magnification. If the eyepiece is now drawn towards the observer the star disc begins to expand, and if the mirror be a truly spherical one the expanded disc will be equally illuminated, except the outer edge, which usually shows two or more dark rings due to diffraction, as already explained. Now if we push the eyepiece towards the mirror the same distance on the opposite side of the true focal plane, precisely the same appearance will be noted in the expanded star disc. If we now place our plane surface anywhere in the path of the rays from the great mirror we should have identically the same phenomena repeated. Of course it is presumed and is necessary that the plane mirror shall be much less in area than the spherical mirror, else the beam of light from the artificial star will be shut off; yet I may here say that any one part of a truly spherical mirror will act just as well as the whole surface, there being, of course, a loss of light according to the area of the mirror shut off. I might go on to elaborate this method to show how it may be made still more exact, but as it will come under the discussion of spherical surfaces I will leave it for the present. Unfortunately for this process, it demands a large truly spherical surface, which is just as difficult of attainment as any form of regular surface. We come now to an instrument that does not depend upon optical means for detecting errors of surface, namely, the spherometer, which, as the name would indicate, means sphere-measurer, but it is about as well adapted for plane as it is for spherical work, and Prof. Harkness has been using one for some time past in determining the errors of the plane mirrors used in the transit of Venus photographic instruments. At the meeting of the American Association of Science in Philadelphia there was quite a discussion as to the relative merits of the spherometer test and another form which I shall presently mention, Prof. Harkness claiming that he could, by the use of the spherometer, detect errors bordering closely on one-five hundred thousandth of an inch. Some physicists express doubt on this, but Prof. Harkness has, no doubt, worked with very sensitive instruments and over very small areas at one time. I have not had occasion to use this instrument in my own work, as a more simple, delicate, and efficient method was at my command, but for the measurement of convex surfaces I know of nothing that can take its place. I will briefly describe the method of using it. The usual form of the instrument is shown in Fig. 2. *a* is a steel screw working in the nut of the stout tripod frame *b*. *c c c* are three legs with carefully prepared points; *d* is a divided standard to read the whole number of revolutions of the screw *a*, the edge of which also serves the purpose of a pointer to read off the division on the top of the milled head *e*. Still further refinement may be had by placing a vernier here. To measure a plane or curved surface with this instrument, a perfect plane, or perfect spherical surface of known radius, must be used to determine the zero point of the division. Taking for granted that we have this standard plate, the spherometer is placed upon it and the readings of the divided head and indicator *d* noted when the point of the screw *a* just touches the surface *f*. Herein, however, lies the great difficulty in using this instrument, *i.e.*, to know the exact instant of contact of the point of screw *a* on the surface *f*. Many devices have been added to the spherometer to make it as sensitive as possible, such as the contact level, the electric contact, and the compound lever contact. The latter is probably the best, and is made essentially, as in Fig. 3. I am indebted for this plan to Dr. Alfred Mayer. As in the previous figure, *a* is the screw, this screw is bored out and a central steel pin turned to fit, resting on a shoulder at *c*. The end *d* projects below the screw *a*, and the end *e* projects above the milled head, and the knife edge or pivot point rests against the lever *f*, which, in turn, rests against the long lever *g*, the point *h* of which moves along the division at *j*. It is evident that if the point of the pin just touches the plate no movement of the index lever *g* will be seen; but if any pressure be applied, the lever will move through a multiplied arc, owing to the short fulcri of the two levers. Notwithstanding all these precautions, we must also take into account the flexure of the material, the elasticity of the points of contact, and other idiosyncrasies, and you can readily see that in an instrument so delicate practice alone will bring about the very best results. Dr. Alfred Mayer's method of getting over the great difficulty of knowing when all four points are in contact is quite simple. The standard plate is set on the box *g*, Fig. 2, which acts as a resonator. The screw *a* is brought down until it touches the plate. When the pressure of the screw is enough to lift off either or all of the legs, and the plate is gently tapped with the finger, a rattle is heard, which is the tell-tale of imperfect contact of all the points. The screw is now reversed gently and slowly until the moment the rattle ceases. and then the reading is taken. Here the sense of hearing is brought into play. This is also the case when the electric contact is used. This is so arranged that the instant of touching of the point of screw *a*, completes the electric circuit in which an electro-magnet of short thick wire is placed. At the moment of contact, or perhaps a little before contact, the bell rings, and the turning of the screw must be instantly stopped. Here are several elements that must be remembered. First, it takes time to set the bell ringing, time for the sound to pass to the ear, time for the sensation to be carried to the brain, time for the brain to send word to the hand to cease turning the screw, and, if you please, it takes time for the hand to stop. You may say, of what use are such refinements? I may reply, what use is there in trying to do anything the very best it can be done? If our investigation of Nature's profound mysteries can be partially solved with good instrumental means, what is the result if we have better ones placed in our hands, and what, we ask, if the best are given to the physicist. We have only to compare the telescope of Galileo, the prism of Newton, the pile of Volta, and what was done with them, to the marvellous work of the telescope, spectroscope, and dynamo of to-day. But I must proceed. It will be recognised that in working with the spherometer only the points in actual contact can be measured at one time, for you may see by Fig. 4 that the four points, *a a a a*, may all be normal to a true plane, and yet errors of depression, as at *c*, or elevation, as at *b*, exist between them, so that the instrument must be used over every available part of the surface if it is to be tested rigorously. As to how exact this method is, I cannot say from actual experience, as in my work I have had recourse to other methods that I shall describe. I have already quoted you the words of Prof. Harkness. Dr. Hastings, whose practical as well as theoretical knowledge is of the most critical character, tells me that he considers it quite easy to measure to 1-80000th of an inch with the ordinary form of instrument. Here is a very fine spherometer that Dr. Hastings works with from time to time, and which he calls his standard spherometer. It is delicately made, its screw being 50 to the inch, or more exactly 0·01998 inch, or within 2-100000th of being 1-50th of an inch pitch. The principal screw has a point, which is itself an independent screw, that was put in to investigate the errors of the main screw, but it was found that the error of this screw was not as much as ·00001 of an inch. The head is divided into 200 parts, and by estimation can be read to 1-100000th of an inch. Its constants are known, and it may be understood that it would not do to handle it very roughly. I could dwell here longer on this fascinating subject, but must haste; I may add that if this spherometer is placed on a plate of glass, and exact contact obtained, and then removed and the hand held over the plate without touching it, the difference in the temperature of the glass and that of the hand would be sufficient to distort the surface enough to be readily recognised by the spherometer when replaced. Anyone desiring to investigate this subject further will find it fully discussed in that splendid series of papers by Dr. Alfred Mayer on the minute measurements of modern science, published in *Scientific American* Supplements, to which I was indebted years ago for most valuable information, as well as to most encouraging words from Prof. Thurston, whom you all so well and favourably know. I now invite

your attention to the method for testing the flat surfaces on which Prof. Rowland rules the beautiful diffraction gratings now so well known over the scientific world, as also other plane surfaces for Heliostats, &c. I am now approaching the border land of what may be called the abstruse in science, in which I humbly acknowledge it would take a vast volume to contain all I don't know, yet I hope to make plain to you this most beautiful and accurate method, and for fear I may forget to give due credit, I will say that I am indebted to Dr. Hastings for it, with whom it was an original discovery, though he told me he afterwards found it had been in use by Steinheil, the celebrated optician of Munich. The principle was discovered by the immortal Newton, and it shows how much can be made of the ordinary phenomena seen in our every day life when placed in the hands of the investigator. We have all seen the beautiful play of colours on the soap bubble, or when the drop of oil spreads over the surface of the water. Place a lens of long curvature on a piece of plain polished glass, and looking at it obliquely, a black central spot is seen with rings of various width and colour surrounding it. If the lens is a true curve, and the glass beneath it a true plane, these rings of colour will be perfectly concentric and arranged in regular decreasing intervals. This apparatus is known as Newton's colour glass, because he not only measured the phenomena, but established the laws of the appearances presented. I will now endeavour to explain the general principle by which this phenomena is utilised in the testing of plane surfaces. Suppose that we place on the lower plate lenses of constantly increasing curvature until that curvature becomes nil, or in other words a true plane. The rings of colour will constantly increase in width as the curvature of the lens increases, until at last one colour alone is seen over the whole surface, provided, however, the same angle of observation be maintained, and provided further that the film of air between the glasses is of absolutely the same relative thickness throughout. I say the film of air, for I presume that it would be utterly impossible to exclude particles of dust so that absolute contact could take place. Early physicists maintained that absolute molecular contact was impossible, and that the central separation of the glasses in Newton's experiment was 1-250000 of an inch; but Sir Wm. Thomson has shown that the separation was caused by shreds or particles of dust. However, if this separation is equal throughout, we have the phenomena as described; but if the dust particles are thicker under one side than the other, our phenomena will change to broad parallel bands, as in Fig. 6; the broader the bands the nearer the absolute parallelism of the plates. In Fig. 5 let *a* and *b* represent the two plates we are testing. Rays of white light, *c*, falling upon the upper surface of plate *a*, are partially reflected off in the direction of rays *d*, but as these rays do not concern us now, I have not sketched them. Part of the light passes on through the upper plate, where it is bent out of its course somewhat, and falling upon the lower surface of the upper plate, some of this light is again reflected towards the eye at *d*. As some of the light passes through the upper plate, and passing through the film of air between the plates, falling on the upper surface of the lower one, this in turn is reflected, but as the light that falls on this surface has had to traverse the film of air twice, it is retarded by a certain number of half or whole wave-lengths, and the beautiful phenomena of interference take place, some of the colours of white light being obliterated while others come to the eye. When the position of the eye changes the colour is seen to change. I have not time to dwell further on this part of my subject, which is discussed in most advanced works on physics, and especially well described in Dr. Eugene Lommel's work on "The Nature of Light." I remarked that if the two surfaces were perfectly plane there would be one colour seen, or else colours of the first or second order would arrange themselves in broad parallel bands; but this would also take place in plates of slight curvature, for the requirement is, as I said, a film of air of equal thickness throughout. You can see at once that this condition could be obtained in a perfect convex surface fitting a perfect concave of the same radius. Fortunately, we have a check to guard against this error. To produce a perfect plane three surfaces must be worked together unless we have a true plane to commence with; but to make this true plane by this method we must work three together, and if each one comes up to the demands of this most rigorous test, we may rest assured that we have attained a degree of accuracy almost beyond human conception. As it is difficult to see the colours well on metal surfaces, a one-coloured light is used, such as the sodium flame, which gives to the eye in our test, dark and bright bands instead of coloured ones. When these plates are worked and tested upon one another until they all present the same appearance, one may be reserved for a test plate for future use. Here is a small test plate made by the celebrated Steinheil, and here two made by myself, and I may be pardoned in saying that I was much gratified to find the coincidence so nearly perfect that the limiting error is much less than ·00001 of an inch. My assistant, with but a few months' experience, has made quite as accurate plates. It is necessary, of course, to have a glass plate to test the metal plates, as the upper plate must be transparent. So far we have been dealing with perfect surfaces. Let us now see what shall occur in surfaces that are not plane.

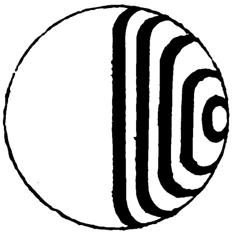

Fig. 8.

Suppose we now have our perfect test-plate, and it is laid on a plate that has a compound error—say, depressed at centre and edge and high between these points. If this error is regular the central bands arrange themselves as in Fig. 7. You may now ask, How are we to know what sort of surface we have? A ready solution is at hand. The bands always travel in the direction of the thickest film of air, hence, on lowering the eye, if the convex edge of the bands travel in the direction of the arrow, we are absolutely certain that that part of the surface being tested is convex, while if, as in the central part of the bands, the concave edges advance, we know that part is hollow or too low. Furthermore, any small error will be rigorously detected, with astonishing clearness, and one of the grandest qualities of this test is the absence of "personal equation," for, given a perfect test-plate, it won't lie, neither will it exaggerate. I say won't lie, but I must guard this by saying that the plates must coincide absolutely in temperature, and the touch of the finger, the heat of the hand, or any disturbance whatever will vitiate the results of this lovely process; but more of that at a future time. If our surface is plane to within a short distance of the edge and is there overcorrected, or convex, the test shows it as in Fig. 8. If the whole surface is regularly convex, then concentric rings of a breadth determined by the approach to a perfect plane are seen. If concave, a similar phenomenon is exhibited, except in the case of the convex the broader rings are near the centre, while in the concave they are nearer the edge. In lowering the eye while observing the plates, the rings of the convex plate will advance outward, those of the concave inward. It may be asked by the mechanician, Can this method be used for testing our surface plates? I answer, that I have found the scraped surface of iron bright enough to test by sodium light. My assistant in the machine work scraped three 8in. plates that were tested by this method, and found to be very excellent, though it must be very evident that a single cut of the scraper would change the spot over which it passed so much as to entirely change the appearance there; but I found I could use the test to get the general outline of the surface under process of correction. These iron plates I would say are simply used for preliminary formation of polishers. I may have something to say on the question of surface plates in the future, as I have made some interesting studies on the subject. I must now bring this paper to a close, although I had intended including some interesting studies of curved surfaces. There is, however, matter enough in that subject of itself, especially when we connect it with the idiosyncrasies of the material we have to deal with, a vital part of the subject that I have not touched upon in the present paper. You may now inquire how critical is this "colour test." To answer this, I fear I shall trench upon forbidden grounds, but I call to my help the words of one of our best American physicists, and I quote from a letter in which he says by combined calculation and experiment I have found the limiting error for white light to be 1-50000000 of an inch, and for Na or sodium light about fifty times greater, or less than 1-800000 of an inch. Dr. Alfred Mayer estimated and demonstrated by actual experiment that the smallest black spot on a white ground visible to the naked eye is about 1-800th of an inch at the distance of normal vision—namely, 10in., and that a line, which, of course, has the element of extension 1-5000th of an inch in thickness could be seen. In our delicate "colour test" we may decrease the diameter of our black spot a thousand times and still its perception is possible by the aid of our monochromatic light, and we may diminish our line ten thousand times, yet find it just perceivable on the border land of our test by white light. Do not presume I am so foolish as to even think that the human hand directed by the human brain can ever work the material at his command to such a high standard of exactness. No; from the very nature of the material we have to work with, we are forbidden even to hope for such an achievement, and could it be possible that through some stroke of good fortune we could attain this high ideal, it would be but for a moment, as from the very nature of our environment it would be but an ignis fatuus. There is, however, to the earnest mind a delight in having a high model of excellence, for as our model is, so will our work approximate, and although we may go on approximating our ideal for ever, we can never hope to reach that which has been set for us by the great Master Workman.

**A Clear Shellac Varnish.**—A simple mode of of clearing turbid lacquer or solutions (however strong) of shellac in spirits of wine, is to add to the same a quarter of their bulk of commercial "benzine" or refined petroleum spirit. If the mixture be agitated three or four times during the space of an hour and then allowed to stand, it speedily separates into two distinct layers, the upper one is a solution of the fatty or waxy matter in petroleum spirit, the lower is a brilliant alcoholic solution of pure shellac. The petroleum spirit only dissolves to a small extent in the other liquid, and the latter when drawn off is easily freed from it by slightly warming, with gentle agitation. Crude lac of any kind may be caused to give an absolutely clear solution in alcohol if it first be roughly powdered and then washed with warm petroleum spirit once or twice so as to dissolve out all the fatty matter. This latter has the advantage of simplicity, while at the same time the quality of the lac is in no degree injured.—*Southern Coach Maker.*

**Gallium.**—Dr. L. Ehrlich, a German chemist, has succeeded in isolating the metal gallium by an industrial process. A preliminary experiment has yielded 0·6 grains of gallium from 80 kilogrammes of zinc blende. The method followed was a modification of that introduced by M. Lecoq de Beisbaudrau, which by lixiviation of the zinc sulphate resulted in a small quantity of mud containing ferric oxide and gallium. The galliferous alkaline solution was then electrolysed in a platinum capsule and the metal deposited in fine needles. As the melting point of gallium is low, about 30·5 deg. C., and its lustre brighter than that of mercury, it may be found of useful application by-and-by.

# SCIENTIFIC NEWS.

THE death is announced of Prof. Morrison Watson, dean of the medical school and professor of anatomy at Owens College, Manchester. Whilst lecturing last month he broke a bloodvessel in the head, and lingered on unconsciously until last week, when he expired. Dr. Watson was only in his fortieth year. He will be remembered by many as demonstrator of anatomy under Prof. Turner at Edinburgh, but was widely known as a contributor to scientific journals, and as one of the experts engaged on the reports of the voyage of the *Challenger*.

The well-known mineralogist and palæontologist, Prof. Dunker, of Marburg, is dead.

At the next meeting of the Royal Microscopical Society, on the 8th inst., at 8 p.m., the original ruling machine of the late Herr F. A. Nobert will again be exhibited by Mr. J. Mayall, jun. Mr. Mayall informs us that, with a view to clearing up the mystery regarding the production of the diamond ruling-points, he has submitted them to the inspection of Messrs. Wellby, the well-known diamond merchants, of Garrick-street, in order to decide which surfaces were artificially prepared and which cleaved, &c. Messrs. Wellby recommended that an independent examination of the ruling-points should also be made by professional diamond cleavers. Accordingly, Messrs. Nyburg, formerly diamond cleavers of Amsterdam, were requested to undertake the examination. The results of the various examinations will be communicated to the Society by Mr. Mayall.

Dr. Luther, of Düsseldorf, discovered another small planet on the 14th of March. It is of the eleventh magnitude, and will reckon as No. 247, No. 245 being that discovered by Mr. Pogson at Madras on Feb. 6, and observed at Berlin and Vienna on the 9th and 12th of March. No. 246 is the small planet discovered by M. Borrelly, as announced on p. 54. Dr. Palisa has named No. 244, Sita.

The Guarantee Fund in connection with the meeting of the British Association at Aberdeen is now nearly all subscribed, amongst the latest contributions being £50 from the Queen. The nomination as President for the Birmingham meeting in 1886 has been offered to Sir W. Dawson, F.R.S., the principal of M'Gill College, Montreal, and has been accepted.

An ascent of Ben Nevis was made last week by two gentlemen, who found the observers in good health and spirits, although the buildings were almost entirely buried in snow. At the half-yearly meeting of the Scottish Meteorological Society last week, the report of the council was read, in which it was stated that hourly observations had been taken during the winter at the Ben Nevis Observatory, except during some hours of the night between the 21st and 22nd of February, when a severe storm prevented a light being carried outside to read the thermometers. The cost of the erection and maintenance of the observatory to the end of January had been £5,935, or £325 beyond the sum received for the purpose. At the meeting, a paper by Mr. Omond, the superintendent of the observatory, on "The Formation of Snow Crystals from Fog," a common phenomena on the Ben, was read.

A meeting in connection with the Marine Biological Association is to be held at the rooms of the Society of Arts on April 13th. Cambridge has undertaken to raise £500 for the station of the Association, and nearly the whole of this amount has been subscribed. The Association has nearly £6,000 in hand, but requires some £4,000 yet before building.

Some rather alarming statistics were recently given by Mr. W. Whitehead, the President of the Manchester Medical Society, when he stated that the number of deaths from cancer had increased from 4,807 in 1849 to 14.057 in 1882, the last return available. Mr. Whitehead did not compare deaths from cancer with population, but with the total number of deaths, and he found that whereas in 1849 out of the total mortality one death in 90 was due to cancer, in 1882 the proportion was one in 36. These figures do not represent the extent of the increase fully, because formerly fibroids, polypi, &c., were included under the head cancer. In 1882 twice as many females died from cancer as males, and the proportionate increase has been greater amongst women.

Prof. Brown-Séquard read a note on the "Local Action of Cocaine," at a recent meeting of the Société de Biologie of Paris. His experiments show that the drug acts through the medium of the peripheric nerves on the nervous centres, which react by producing an inhibition of sensibility.

On p. 384, No. 1,006, we described a method of making maps in relief patented by Mr. J. de Mendonca Cortez, president of the Banco Lusitano, Lisbon. Maps prepared on his plan have attracted the attention of the War Ministers of France, Germany, and Italy, but they might with advantage be utilised also for the purposes of elementary education.

It was thought that Herr Lenz, who is going out to explore the region of the Congo on behalf of the Geographical Society of Vienna, would also be commissioned to represent the similar societies of Berlin and Munich. It appears, however, that the Berlin Society has determined to send an explorer of its own, and Dr. Fischer will proceed to Zanzibar some time this month, and will journey thence to Uganda and the watershed of the Upper Congo.

At the annual meeting of the Institute of Naval Architects, which was held last week, the president, Lord Ravensworth, stated that the diminution in shipbuilding for all ports during the past year amounted to the equivalent of seven and a half millions sterling, which would account for much of the distress and privation borne by the industrial classes during the past winter. The president, amongst other points, also referred to the increasing use of high-pressure steam, 150lb. being now common, while triple expansion engines, he thought, threatened to oust all others. A number of papers of more or less interest were read, including one by Mr. Thornycroft, on "Guide-Blade Propellers for Shallow Draught Vessels." He considers that the guide-blade propeller will beat the paddle-wheel (stern wheel), as its only defect is a limited power to propel astern.

The technological examinations of the City and Guilds Institute will be held at the different centres on May 20 next. Candidates who cannot arrange to attend at any of the provincial centres can, on application to the director and secretary, be examined at the Cowper-street Schools, London. The programme, containing syllabus of each subject and last year's questions, can be obtained from the secretary, Gresham College, E.C.

Mr. Coxwell, referring to some statements as to the lifting power of hot air and gas in balloons, says that the average specific gravity of coal gas is such as to lift only from 35lb. to 40lb. per 1,000 cubic feet, and to lift 40lb. it must be prepared from a dry coal and be well purified. Even hydrogen cannot be made to lift much more than 60lb. per 1,000 cubic feet.

Vaseline is, it seems, used as a substitute for lard or butter in pastry by some of the confectioners of Paris. M. A. Riche recently presented a report on the subject to the Council of Hygiene of the Department of the Seine, in which he states that however advantageous its use may be to pastry makers, because it has no tendency to become rancid, the employment of vaseline for alimentary purposes ought to be interdicted as injurious to health.

**Compressed Teak for Loom Shuttles.**—The increase in the price of boxwood, largely used in the manufacture of loom shuttles, has directed attention to the possibility of producing some cheaper material equally suitable. It has been found that compressed teak will answer the purpose, and a powerful hydraulic press has just been completed by Sir Joseph Whitworth and Co., of Manchester, for Mr. Robert Pickles, of Burnley, to be used in compressing this class of timber for the manufacture of loom shuttles. The press consists of a strong cast-iron top and bottom and steel cylinder, with a large ram. In the centre of this ram is fitted a smaller ram, with a rectangular head fitting into a die which is placed on the top of the large ram. The timber is put into this die and a pressure of 14 tons per square inch is applied. The pressure is then relieved, and the large ram descends. The top pressure block, which fits the die, is afterwards removed, and the small ram rises and pushes the compressed timber out at the top of the die. The timber thus treated is made very dense, uniform, and close grained, and is capable of taking a very high finish.

# LETTERS TO THE EDITOR.

### THE MISSING PAIR Σ. 1143.

[24035.]—In the ENGLISH MECHANIC, of Feb. 6, there appeared an interesting letter (23794) by Mr. H. Sadler on "The Missing Pair Σ 1143." I have examined the two stars lettered by him A and B on several occasions with my 7½in. refractor; but have as yet failed to detect a companion to either of them in the position given by Struve. There is, perhaps, not much interest attaching to a negative result of this kind, except as showing that an attempt has been made to solve an interesting question. I shall endeavour to keep the stars under occasional observation. On Feb. 18 I gauged the magnitudes of the two stars thus:—A 8·9, white; B 7·1, ruddy orange.

**George Knott.**

### GRINDING AND POLISHING GLASS SPECULA.

[24036.]—I HAVE directed the amateur in a previous letter to slope the sides of his facets to an angle of from 45° to 55° with the radius of the curve of the face of his polisher. Now this is a very important element towards certainty of results, and therefore success; and to impress its importance on the memory of the amateur, I will explain the results of some of the many experiments I have made to investigate the laws that are brought into action by the various slopes of the sides of the facets.

Now here I must explain to the amateur that one great indication of the face of the polisher being all right is the regular revolution of the polisher; but he will remember that I directed him to put the pushing rollers that are attached to the under-side of the ring that encircles the polisher a little in advance of the middle line, so that at each push the polisher is really pushed a little round in the ring, and thus forced to go round against any accidental cause tending to irregularity. Now, this is all right when all the conditions are as perfect as can be obtained, and they are all well understood and mastered practically; but when we want to try experiments, we have to reduce the strongly controlling conditions, so that the laws we want to discover shall not be overborne in their action, and thus never become visible enough to enable us to study them with certainty. The pushing rollers must, therefore, be put within ⅛in. of the centre line of the push, where they will exert but little influence on the revolution of the polisher in the ring, all the other conditions are the same as those I have explained as necessary to produce the parabola, except the sides of the facets, which we are about to experiment upon. I first wished to try the effect of perpendicular sides upon facets that were narrower than they were thick, as well as upon facets that were broader than they were thick. I therefore made a polisher with the centre facets ½in. square, and the others graduated so that the outer ones were $\frac{3}{16}$in. wide on the edge of the polisher, and all ¼in. thick. Now this amount of graduation, with sloping sides to the facets, will about produce the parabola, the same as though the centre facets were ¾in. square, and the others graduated to ⅜in. at the edge of the polisher. The above polisher that I made to try these experiments with, allowed me a wide range of proportion, varying from the outside facets being thicker than they were wide, to the centre ones, which were double as wide as they were thick. I tried to figure, or rather polish—for figuring was out of the question with such a polisher, for all the regularity of the revolution of the polisher had gone. Now it was jumping round in one direction, then in the opposite direction, then standing still, then moving quietly in the direction of the speculum (the right direction), then it would start off with a jerk in the opposite direction, and thus it kept on during the whole time I experimented with it, which extended over several half-hours' workings. Of course I had not been watching the jerkings backwards and forwards of the polisher many minutes before I began to anticipate the cause—namely, the want of support to the sides of the narrow facets, causing them to bend on one side, and thus either be bent below the general level, and thus give a preponderance of cut somewhere else, or else the bending of the narrow facets on one side, causing one edge to project above the general level; and these raised edges coming in contact with the edge of the speculum would cause points of resistance, and so cause the polisher to be pushed round on these points as centres. Thus, if the point of resistance was one time on the right-hand half of the polisher, then the polisher would be pushed round from right to left; then, perhaps, the point of resistance would be changed to the left-hand half of the polisher; when it would cause the polisher to be pushed round from left to right; and so on, ever varying with the bending, however slight, of the weak facets, first on one side, then on the other, some of the facets even breaking off. Upon examining the facets I find what I expected—viz., that the $\frac{3}{16}$in. wide facets represented in Fig. 1. A, full size, were some bent as shown in B; the face being just slightly below the general level, so as to be out of action, while others were bent, as shown in C; the bite of the rouge having pulled or bent up one side above the general level, only to be caught by the edge of the speculum to be pushed still further out of shape. This disturbance of the shape of the facets decreased as I approached to the centre; those facets that were as broad as thick, as shown in D, were only slightly bent, as in E, while those that were double as broad as thick, were apparently not affected, but stood well; the peculiar effect of their perpendicular sides could not be seen, but was made manifest in another experiment I will describe further on I may just observe that the experiments I describe are by no means all I tried; but they are those that I discovered laws by, or that will show to the amateur the nature of these laws.

Now it is very evident that the narrow facets A B C D E wanted more support on their sides to prevent them yielding sideways. What amount of support is necessary, the amateur will readily understand from the following reasoning: I told him I found those facets whose base was twice their height seemed not to yield sideways, but to maintain their shape. Such a facet is represented in Fig. 2, where it will be seen that the centre perpendicular line A B has the support of an angle of 45° on each side, viz., A C B and A D B; this angle, then, I concluded, was the smallest allowable, so as to be perfectly free from alteration of shape during polishing; in other words, the base of the facet must be not less than double its height. We shall see further on the need of sloping sides even to such proportioned facets.

I next made a polisher with all the facets ½in. square and ¼in. thick, the sides being perpendicular. I polished with this for several half-hours and found, as I expected, the figure of the mirror to be as shown in Fig. 3 with the well-known pecking in, and rise in the centre, clearly indicating that all the facets were acting alike, the same as a solid metal tool; of course, the only thing to be done is to graduate the facets towards the edge, so as to reduce their resistance, and thus proportionately increase the resistance, and therefore wear, on the centre of the mirror, and so to lower the elevation seen in the centre, and thus produce the spherical surface, to be carefully altered into the parabola, when we are parabolising by a carefully conducted further graduation or reduction of the facet towards the edge, and thus slightly increasing the proportionate resistance, and therefore cut of the centre facets, to sink the centre of mirror below the spherical curve to the required amount to produce the parabola; but, of course, this refinement I was not going on to with this polisher, as I was only experimenting upon the effect of various sloping sides to the facets. I may just observe that with every new-made polisher I tried experiments, such as the alteration of shape, allowable before I got to the shape I made the special polisher for, gave me the opportunity of trying; I kept notes of what experiments I wished to try to determine certain points, and these experiments I tried on new polishers, so as to use up their full shape; that allowed me to make the facets of the required form to decide certain doubtful points; otherwise one would have had to be making new polishers for every experiment; thus, during my experiments, I had always some modification to introduce into every new polisher to decide or discover or confirm some supposed law, and thus I often confirmed my previous conclusions over and over again upon new polishers, before I brought them to the shape I specially and finally required them to be. I mention this as a hint to future experimenters, as utilising new-made polishers and saving much time in making polishers, too. I now wanted to decide this question that was among my query notes—viz., Is it the increased area of the larger centre facets in a graduated polisher that wears down the elevation shown in the middle of Fig. 3, or is it the increased resistance of the large centre facets, on account of their increased width of base as compared with their thickness? Now, with the polisher in hand, I had only to graduate the face of the facets, beginning with not toughing the sides of the facets near the centre of the polisher —i.e., leaving them perpendicular and sloping the sides of the facets towards the edge of the polisher, so that the faces of the outside facets should be ⅛in. wide, which graduation, with the ½in. square centre facets, would produce the parabola if the slides were all sloped to an angle of 45°; and, therefore, the above polisher ought to produce the parabola, if the parabola were produced by the alteration of the area merely of the faces of the facets, for, as said before, the area is the same as would produce the parabola if the sides were sloping to an angle of 45°.

I represent in Fig. 4 A one row of facets from centre to edge, to make plain to the amateur the conditions this important experiment was tried under. Now, I polished with this polisher for several half-hours, and not a bit of reduction of the elevation in the centre as shown in Fig. 3 took place; the elevation was, if anything, increased, showing that it was not the increased proportionate area of the centre facets of a graduated polisher that reduces the elevation in the centre of the speculum (Fig. 3), but the increased resistance of the larger facets (with equally sloping sides with the smaller outside facets) over the less resisting, because smaller, outside facets. And further, we learn that the perpendicular sides were no more support than if they had been cut away, leaving the sides to an angle of 45°, and thus reducing the area of the centre facets to the same as the outside, for it will be remembered that with the equally-areaed facets the same figure was produced. The revolution of the polisher was much more regular, however, but not perfectly so. This improved regularity of motion in the polisher was produced by the support afforded by the sloping sides of the outer smaller facets.

FIG. 1.

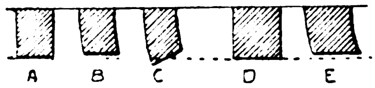

FIG. 2

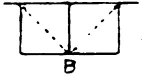

FIG. 3

FIG. 4

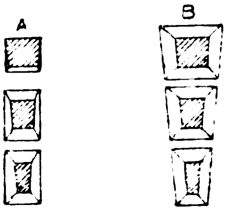

FIG. 5

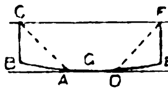

FIG. 6

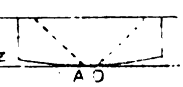

Now, to still further confirm my increasing convictions and conclusions, that it is the resistance far more than the area that does the parabolising or the sphericalising, if I may so call it, when the mound in the centre of Fig. 3 is reduced to the common spherical curve of the outside part by graduating previous to parabolising, I now proceeded to try the following experiment with the polisher: I filled up the perpendicular sides of the facets with pitch, by melting the end of a stick of it, as we do sealing wax, and letting it drop into the angle adjoining the perpendicular sides till filled up, then melting it thoroughly into all the crevices with the end of a hot iron wire, and finally cutting the superfluous pitch off with my razor to the required 45° angle; thus I added the same support to the centre and intermediate facets as I already had to the outside facets, but leaving the area of the facets unaltered from the last experiment—the altered form of the facets I show in Fig. 4 B. I now proceeded to polish with this polisher, with the certainty of what the result would be, for I had worked the parabola with such a polisher many a time before. Well, after the first half-hour's polishing, the elevation in the centre of Fig. 3 had almost gone, and another half-hour's polishing had completely reduced it to the common spherical curve of the outside parts, conclusively showing that the increased support had given the necessary predominant resistance, and, consequently wear, to the centre facets necessary to increase their cut (by resistance, not increased surface) so as to sink the centre more than the outside, and thus produce the sphere first; when, if the resistance is increased a little more, the parabola will follow. The revolution of the polisher now became pretty regular.

I may here observe that in the previously-described experiments I had made my polisher with ½in. square facets, so as to allow more room in the grooves to experiment upon different angle of sides. But I had better here state that I have found the larger the faces of the facets, in other words, the less the grooves the better the surface of the glass is; therefore, in actually finishing a mirror, I have the centre facets ¾in. square, and graduate the outside to what is needed to produce the parabola.

From other experiments, which would take too much space and time to describe in detail, I find that a facet with a base of ¾in. square, but with perpendicular sides, and consequently with a face ¾ square, has far less cut than a facet on the same sized base, but with sloping sides at 45°, and consequently with an area many times less; in fact with perpendicular-sided centre facets, it is only just possible to reduce the mound shown in Fig. 3, when the outside facets (with sloping sides, of course) are reduced at the edge to nothing on their face. How this comes about the amateur will easily understand from Fig. 5, where it will be seen that as the angles A, B, C, and D, E, F, of the facet have no support, they are easily pushed up by the rouge, which acts like a wedge, the thin end of which, getting in, will push its way beyond the limit of the 45° angle shown by the ends A, D of the dotted lines, aided by the leverage, if I may so describe it, of the pitch from A to B and D to E, so that instead of leaving the polisher in contact from A to D, the pitch at A and D is actually lifted above the surface of the speculum by the wedge of rouge, lifting the surface (the levers, if I may so call them) G B and G E, and thus carrying with them part of the surface from at A and D towards the centre G of the face B G E, and thus reducing the contact surface of the facet to what is shown in Fig. 6, where the part included in the dotted lines shows the really effective part of the facet, leaving an effective surface A D in contact with the speculum less than if the facet (Fig. 5) had its area reduced by having its sides cut to an angle of 45° as shown included in the dotted lines, when the whole of the surface, A D, would have been kept in contact.

I think by this time the amateur will see the reason why I have directed him to have the sides of his facets sloped, and why I have made so much of its importance in my previous letter, knowing as I do how much it conduces to the regularity of the motion of the polisher, and while an angle of 45° will do, I think to be on the safe side an angle of 55° is better, and for the following reasons. I have explained in the first part of this letter how the edge of a square-sided facet is apt to be pulled down or pushed on one side, so that in the former case to increase the local resistance so as to cause the polisher to swing round on it, either backwards or forwards, according as the resisting edge is on the right-hand half or left-hand half of the polisher for the time being. In the latter case the local resistance would be decreased, thus making the preponderance of resistance to be on the opposite side of the polisher. To determine at what angle these causes of irregularity in the motion of the polisher cease to act, I made a polisher with perpendicular-sided facets, then cut their sides to an angle of 10°, then polished, noticing how the polisher moved round, then increased the angle to 15°, and noticed again; I found the jerking of the polisher was reduced with every increase of angle, and thus I proceeded till I got to 45°, when the polisher began to move pretty regularly round. I then went on to 50°, and so on till I reached 70°; but there was little or no improvement beyond 50° angle, so that I came to the conclusion that from 50° to 60° would be perfectly safe; but I believe the greater the angle the better, since the rouge will have, if I may so speak, a better supported lever of surface to resist the thin end of its wedge-like action.

I may here be allowed to call the attention of amateurs to the fact, as bearing on this subject, and corroborating my conclusions, that the late Dr. Lassell used square-sided facets for his polisher, and that he found the tendency to irregularity in the motion of his polisher such that he had to devise a very elaborate system of wheels for his first machine, and pulleys and wheels for his last machine, to control the revolution of the polisher and make it revolve at about the rate he found it would naturally when acting at its best. Now, I believe that the perpendicular sides of his facets had very much to do with the irregularity of the motion of the polisher, and that had he sloped the sides of his facets to an angle of from 45° to 55°, he would have had little or no trouble from irregular motion of his polisher, since the resistance would have been kept equal all over the polisher, thus leaving the combination of motions and resistances to produce, without accidental interference from perpendicular sides, a regular revolution of the polisher.

## LUNAR OBJECTS.

[24037.]—THE following are notes of lunar features which have been observed, with a comparison of them, as shown on the maps of Neison, Schmidt, Mädler, and Lohrman. On comparing the various maps with the moon we must, I think, come to the conclusion that Schmidt's is by far the most perfect, and that future efforts will be well directed towards rendering it yet more perfect, and clearing up discrepancies between it and others. Schmidt's map being on a larger scale, is likely to show many things omitted by others, but it is not often that we find Neison showing objects that Schmidt omits; yet sometimes this is the case, and it becomes important then to find out by observation which is correct; also, as Schmidt's sections do not overlap, it is sometimes difficult to make sure what he shows at the divisions; perhaps, therefore, it would be useful to direct attention to these parts and to make drawings of them.

On Feb. 4, 1885, I observed a very well-marked cleft, from the middle of the east wall of Theophilus half way to Hypatia. On Mädler's map alone can it be distinguished as a valley marked *x*. It was also seen by me in 1881. A valley which lies from E. to W. of the north wall of Theophilus on its slope is often conspicuous, but does not appear on either of the above maps. On Dec. 6, 1884, its eastern part was seen to be composed of three craters in a row, and one a little way west of them, from which the cleft extended quite to the western edge of the wall, bending a little with the curve of the wall.

On Jan. 5, 1885, I noticed a valley crossing the west wall of Cyrillus obliquely from its crest to the floor. This also is not shown on either map.

The western wall of Catharina is divided in an oblique direction, S.W. and N.E., so forming a valley or chasm. This is shown by Mädler and Lohrman, and best by the latter.

On Feb. 4, 1885, there was seen very plainly a good-sized crater on the S.E. part of the floor of Eudoxus. It is not shown on either map. Schmidt's map cuts through Eudoxus, so that it is not easy to see what he shows. On Feb. 22 a valley was seen between two mountains, which seemed to lie more west than the crater, which was not then visible. This valley is shown by Lohrman and Schmidt. Last August some small hills or craters were seen near the northern wall. There is some discrepancy in the objects shown in the various maps. There is a difference also in the size of the craters A and B, as shown by Neison and Schmidt. The former shows them the same size; but A is really a good deal larger than B, and is thus shown by Sch., Lohr., and Mädler.

On Feb. 5 and other occasions the crossed clefts east of Eudoxus were well seen. At each end of ξ, on its eastern side, lies a small crater. Perhaps there is another crater or a hill on the western side of its southern end. These are not shown by Neison or Sch., but the clefts are well shown by both. The clefts end at the foot of a peculiar shaped mountain on the north. Sch. does not carry them beyond the spot where they cross one another; but I was able to trace them beyond this into the two hollows of the mountain as easily as through any part of their course. Perhaps Mädler shows one cleft and Lohr. both. The latter draws the shape of the mountain best. Neison's two clefts ζ could not be seen; they must either pass through this mountain or lie north of it.

On the north border of Alphonsus I observed a valley on Feb. 6, 1885, at 18h. 13m., which is not shown on either map satisfactorily. Lohr. partly shows it. It was very plainly visible, commencing near the northern end of the principal clefts which cross the floor from N. to S., and passing over the wall of Alphonsus and Ptolemæus, which are here coincident; it ends at the foot of the wall of the latter.

The conspicuous cleft on the south side of Archimedes was seen on Oct. 10, 1884, to be formed of craters. Neison only places the letter δ in its position, and the other maps show nothing there.

Of the very conspicuous valley west of Macrobius, Sch. only shows part of one, nor do they appear on the other maps, though they can be best made out on Lohrman's. There are two long and nearly parallel valleys lying in a N. and S. direction, crossed by one transverse, which is continued over the crest and down the slope of the west wall of Macrobius. South of these, and between Macrobius and C. lies another long valley.

In Littrow, Sch. and Lohr. show nothing, while Mädler and Neison draw a ridge and some small white spots. As it is an uncommon occurrence for Mr. Neison to show more detail than Sch., I watched Littrow for some months, but without seeing the least trace of anything. I had never seen anything previously. On Feb. 2, 1885, however, a small white spot and a narrow white streak were very faintly visible. On the next night they were even less distinct, though just traceable. They were seen again faintly on March 4. The direction of the streak is not exactly that shown by Mädler and Neison; it extends from the crater on the S.E. wall to the brilliant mountain on the N.W. wall. The white spot lies on its southern side. The crater is at the foot of the broad outside slope of the S.E. wall, and is only shown by Mädler and Schmidt. On February 3 a small and well-defined black spot lay on its western side. Another crater, perhaps, lies on the S. wall, further west; but is not shown on the maps. On the same date there was a sharp and narrow line of shadow through the N.E. and the S.W. wall; but not corresponding to one another in direction, though being somewhat in the direction of Mädler's streak. If the streaks are clefts, there may, therefore, be two crossing the floor. A little way south of Littrow lay a large mountain, divided into three portions by two similar short, straight black lines, one of which might have been an extension of the line through the south wall. A large, round spot of shadow lay between it and the wall. It is clear that the objects on the floor and walls of Littrow require to be reobserved, in order to obtain a correct representation, as the maps differ so much.

North-east of Beaumont is a crater rill, which is often visible, though very delicate, ending at the most eastern of the two ridges from Beaumont to Theophilus, which is so rarely visible. I have seen the rill in the years 1881 and 1882, and again in 1884, Aug. 10th, 15h. 30m., and Oct. 8th. It is not the one which Neison mentions as having been seen by Schmidt doubtfully; the position of that, as given in Neison's description, is N.E. of A., while this lies S.E. of that crater. Its north-western end is just south of A., and it extends to the group of craters E. of Beaumont. Almost exactly in its place Schmidt draws four small and separate craters in a row, and a larger separate one at each end of the row. This is plainly the same object; but whenever I have seen it, it has been as a true crater-rill, and extending further than his row of craters. Mädler shows three small craters in a row, nearly in its position; Lohr. shows nothing similar to this.

On the west wall of Franklin Neison draws two conspicuous craters, marked *g*, which are not shown by Schmidt. He also draws one on the N. wall. He does not draw the large crater a little distance from the N. W. wall, near which the cleft passes towards Cepheus, unless the one first mentioned on the N. wall is intended for it. Schmidt shows a conspicuous crater on the S.W. wall, and a smaller one close to it, also a crater on the N.E. wall, and two craters near the junction of Franklin and *f*. These are all omitted by Neison. Schmidt also shows the crater some little distance from the N.W. wall with another, smaller, between it and the cleft. Mädler shows the crater some way from the N.W. wall, and *g* as a large crater. On Lohrman's map the wall at *g* is divided, showing two mountains; but Schmidt gives neither the division nor the peaks. Lohrman draws two other peaks on the west wall, one being in the position of Schmidt's south-western crater. A division in the N. wall is shown by Lohrman and Schmidt only. It is strange that Schmidt does not show *g*, for it is drawn as a large crater by Mädler and Neison. On August 8, 1884, I noticed that it was not visible, nor do I remember seeing it at any other time.

The differences in *f* shown in the various maps are as follows:—Neison and Mädler show a central hill and a ridge from the south wall of Franklin; Lohrman shows the ridge very conspicuously ending in a peak; Schmidt two central hills only. On February 2, 1885, I saw the ridge very distinctly.

The central mountain in Euler, which is very plainly to be seen, and which is shown by Mädler, Lohrman, and Schmidt, is not shown by Neison.

**M. A.**

## CUTTING SCREW-THREADS.

[24038.]—IT is clear from "Vulcan's" last letter that our propositions have got into confusion. At page 560 Mr. Wenham asserted that, in cutting an angular thread of 50°, a revolving V-cutter or V lap-wheel does not give the same-shaped thread as that given by a fixed V-point tool or chaser of the same angle and tilted to the same pitch. I then had to point out that Mr. Wenham had nodded. At page 35 Mr. Wenham, *more suo*, neither justified nor corrected the statement which I had impugned, but produced the usual red herring and went on to argue about "a circular saw," "a square-thread screw of coarse pitch," and "a pair of skew gear wheels." I like red herrings, sometimes, and it is always interesting to study the way in which Mr. Wenham uses them to save himself from the dogs. But what we now say is that Mr. Wenham is wrong, and I ask him either to acknowledge his error or to show where my error is. I may add that Mr. Wenham's proposition is contradicted by Mr. Hines (page 14), and by "Vulcan" (page 35). In practical mechanics the question is one of considerable importance, and there ought to be no fog about its answer.

At page 60 (23973) "Vulcan" now raises a question altogether different, but one which deserves careful consideration. Of course, the cross section of a screw-thread is affected by the angle at which the thread is cut across. The *normal cross section* is made at right angles to the line of the thread, and, for all questions depending upon thread form, it is the section to be regarded. The spiral surfaces of a screw-thread are all ruled surfaces, and are not developable. The only elements which are developable are the spiral elements or the surfaces upon a given *pitch cylinder*. The normal cross-section of the screw-thread is given by a second ruled surface crossing the thread at right angles, and having each transverse radial element to the cylinder on which the thread is cut. Such a section would be given by *one edge* of a square fly-cutter revolving upon an axis parallel to the hypothenusal line which gives the pitch of the thread. The traverse of such revolving cutter-edge would have to describe a spiral surface at right angles to the path of the thread, and radial to the axis of the screw. If the thread were cut without traverse, so as to be an annulus upon the cylinder, and return into itself instead of advancing as a spiral screw-thread, then *the normal section* of the thread would also be its *axial section*, and would be shown in the ordinary diagram of a screw bolt cut by a plane passing through its axis. Our angular thread of 50° pitched to the rate of eight or ten turns to the inch, will have for its axial section a base about as much wider than that of the normal section, as is its secant. If the thread were cut upon a plane surface, the secant of the angle at which the cross-section were made would give the exact length of its base. An annular thread would appear as a ridge normal to the base, and the secant would be 1. An eight per inch thread upon an inch nose would be a hypothenusal ridge at an angle of about 2° 15′ from the normal, and its secant would be 1·0007716. This would make the axial cross-section ·0002in. longer in the base than the normal cross-section—an increment which is negligible, and therefore not before referred to.

In all cases, upon a plane surface, the groove cut will be the counterpart of the cutting plane—this being tilted, so as always to be normal to the line of its traverse. Upon a rotating cylinder the cut is equally a counterpart, but a counterpart modified by the cylindrical curve of the surface upon which it is cut. This modification it is which makes it a screw-thread, and to call the screw-thread "deformed" because of this would be absurd. Nor is this the question raised by Mr. Wenham, who denied the similarity of action between a cutter revolving and a cutter fixed. Instead of the revolving cutter being liable to give a distorted thread, it is the fixed tool which involves that liability, because it is difficult to keep its cut exactly upon the line of centres. This has been well shown by Mr. Hines.

I cannot see what "Vulcan" means by "the angle in a plane of revolution of axis of screw." The normal cross-section of a spiral thread will in all cases be a portion of a spiral surface, and therefore not developable, nor capable of being represented upon a plane except by projection. This spiral surface, or *normal helix*, will be screwed other-handed and to a hypothenusal line whose angle is the complement of the pitch of the thread —i.e., pitched from the axis as much and in the same direction as the thread is pitched from the plane of rotation. Thread-rate in reference to change-wheel calculations is necessarily axial, inasmuch as what we cut is a given number of turns per axial inch of the cylinder. As the line of the *normal helix* is hypothenusal, it will, for a given length of cylinder, always be longer than the axial line. But, for a given number of threads, the normal helix is the shortest possible line. The *stress* borne by a screw-thread is not axial but normal, inasmuch as it is resolved into its components. Therefore, the normal cross-section is the one to which regard should be paid in calculating the strength of thread.

The idea that a more correct form for the lap would be obtained by first cutting a thread by a chaser is a mistake. It is not possible to cut a correct thread by any multiple-point tool. No multiple-point tool can be made as accurately as a single angular point. The multiple points of a cutter wheel can be finished off more accurately than a multiple-pointed chaser; but nothing can equal the accuracy of a single-point tool used as a revolving cutter, or fixed in the slide-rest and traversed under the guidance of change wheels. If all the teeth of a chaser could be ground to equal angles, there would remain the impossibility of getting all their points at equal distances from each other. The result of any failure to make each tooth follow exactly in the track of its predecessors would be to narrow the thread and to deform the groove.

It is always refreshing to see the courage with which Mr. Wenham advances his theories, and the vigour with which he defends them or the skill with which he runs away. If it were possible for anyone to make the readers of the English Mechanic believe that a V-shaped lap or revolving cutter would produce a groove different from that of a V-point tool fixed in the slide rest and set at the same rake, it would be Mr. Wenham, and the more so, because in practical matters we are indebted to him for valued help. **James Edmunds.**

Grafton-street, Bond-street.

### LATHE MANDRELS.

[24039.]—I should like to thank Mr. Wenham, Dr. E., and others, for the interesting matter they have brought before us on this subject, and was much pleased to hear of the cone and key fitting described by Mr. W. Mr. Wenham's letter this week confirms my impression, that whilst Dr. E. is writing of a V-thread, Mr. W. writes of a square one; what he says of the angular difficulty is evidently true of the square thread; but has not, as far as I can see, been proved true of the V-thread of Dr. E. **F. A. M.**

### LATHE MATTERS.

[24040.]—Neither Dr. Edmunds nor myself have ever suggested that "a square thread screw of coarse pitch" can be ground up true by means of a revolving wheel. The contact here would be—not a V-line, but a line and two surfaces, and until two spiral surfaces can be made to coincide with the plane sides of a square-faced grinding wheel, a square screw thead will not allow a counterpart revolving cutter to clear its sides. But there *is* one way in which an extremely true square thread screw of any pitch *can* be finished off by grinding up, and when Mr. Wenham has set himself right on the present question, I shall be very pleased to explain it unless it is done by Dr. Edmunds.

Mr. Wenham seems to imagine that highly-carbonised tool steel is the only "very finest and best quality of cast steel." On the contrary, we now make our taps of a special description of steel which consists of a shell or cylinder of cast steel, which will harden perfectly, and having a core of mild steel which will remain soft, thus securing the advantages of toughness and strength with perfect cutting edges. In some cases, notably in very large mandrels for double-geared lathes, we select a special quality of mild, sound, homogeneous steel such as has already been described by Dr. Edmunds (page 542, No. 1039), and this, of course, we case-harden.

As to the diamond tools for cutting untempered steel, we all know that, as a laboratory experiment, they can be used, and more diamond tools are made to-day than at any previous period, not for turning up hardened steel surfaces, but for trueing up grindstones and emery-wheels, and turning and cutting granite, porphyry, and similar substances, grooving mill-stones, &c., that it is a very old system of turning up hardened traversing mandrels I have distinctly stated, for Cawdron, my great-uncle, who founded the business which I now conduct, regularly used them for the purpose 70 years ago. But the question is, whether, with our modern emery-wheels and other devices, the use of the diamond is a preferable method? None of the ornamental tool-makers use it for their fine hard steel work, and I believe that none of our great engineers do so. Why not, if the method be a practical one? We want accurate and detailed facts upon the subject. Mr. Wenham's correctness may be tested by any reader who has a fine lathe, and who is, as he says, "knowing enough to test its nose with the corner of a file." I venture to say that, but for an accident, the nose of every such lathe will be found to be *soft*, and purposely left so for a reason which is well known to skilled makers. It will be recollected that in a previous letter Mr. Wenham proceeded to show how to soften the nose of a hardened mandrel by means of a hot poker thrust into it, yet, now that I am obliged to differ from him, he endeavours to assail my tools by asserting that if the screw nose is soft they are not good. I need not follow Mr. Wenham about "a screw turned absolutely true, and this truth retained in hardening." It is quite *possible* to arrive at very great accuracy in hardened steel screws, taps, &c.; but such accuracy as Dr. Edmunds requires for his interchangeable mandrel could not be depended upon without grinding up.

"E. J. S." has again favoured us with interesting and suggestive letters; but on these I will write only a few words, for by his letter (23975) he evidently misunderstands what I have stated. He *had* advocated a "long cylinder fit," apparently as a substitute for the Edmunds mandrel face, and I showed that such an arrangement would at the points of entrance wear sufficiently to render it an imperfect system. This has nothing whatever to do with a *taper* fit, which I believe I was the first to introduce as an interchangeable system for lathe centres and drills—in fact, I still continue to supply drills to clients in India, Africa, and Australia, which run perfectly true in spindles sent out a dozen years ago, and this shows that in my manufactory work "to the fraction of the thousandth part of an inch can be produced." I have also always been an advocate for large bearing surfaces, and I was one of the first to apply them.

The suggestion, however, of a second cylinder-fit at the end of the nose is most unpractical. One cylinder-fit, the thickness of a florin, properly placed, as a "stop-surface," will answer every purpose, and its wear in a lifetime will, as I have said, be infinitesimal. To attempt to prevent the "angular variation" by means of a cylinder-fit—single or double, long or short—is a practical absurdity. Nothing of this sort can compete with the wide face of the Edmunds model mandrel-head.

I am so clear that this mandrel-head will be a great improvement in our ornamental lathes, that I am now busy perfecting my patterns and gauges for new model headstocks, which without being more expensive to my clients, will be a great advantage to them. Not only will the chucks, as Mr. Evans says, be absolutely transferable, but we shall get rid of the expense and bother of the old transfer chucks. We also throw overboard the old complicated and unmanageable ornamental lathe-threads, and, as "Z. Y. X." amusingly puts it, "an amateur will be able to go out to spend the evening with a friend and take his chuck with him."

I have to thank Dr. Edmunds for the loan of the models which he exhibited, and for every kindness in reply to my inquiries. **Edward Hines.**

### LAMINATED ARMATURES.

[24041.]—Respecting Mr. H. Harcourt's letter 23933, will *he*, or *they*, kindly each make *their* own statement? One saying I looked at the pieces of iron, a second he filed the sharp corners off, a third he threaded them on the spindle, a fourth he held them on in position, and the united host screwed them up; for, according to H. Harcourt's *neighbour* (F. Walker, in letter 23959*), he states that at least 1in. of compression is required before the laminated discs are screwed sufficiently tight on armature spindle. Now, F. Walker, in letter 23410, Vol. XL., describes a dynamo in which a cross form of laminated armature is used. This armature in question, see Fig. 5, page 136, Vol. XL., will hold little more than half the wire that a Siemens armature of the same dimensions holds—that is, if I may judge from the proportions he gives therein. He further states that he gets on an armature spindle 5½in. in length, 150 discs of sheet iron, the thickness of each being $\frac{1}{20}$th of an inch. In other words, 7½in. thickness of laminations he gets on a spindle 5½in. in length. This is equivalent to compressing the discs about 30 per cent., and by means of a *screw on a ⅜in. spindle*. Hence my suggesting the united co-operation of H. Harcourt and his clique in screwing up this multum-in-parvo laminated armature; that is, supposing the thread and spindle would stand the pressure required. F. Walker has still left unanswered the query 54934, Vol. XL., where "Likervize Walker" asks, "How does Mr. F. Walker get 150 discs, each 1-20th of an inch thick, on to a spindle 5½in. long?" Again referring to above query in No. 1,027 "Cyrax" says, "It is a pity that Mr. F. Walker should have made such a blunder. . . . Mr. F. Walker might explain how he gets 7½in. of discs on to a 5½in. spindle, because that would be news?" If he, in his last letter (23959), refers to the *one inch compression* required for the 7½in. thickness of laminations on spindle, "Likervize Walker," "Cyrax," others, and myself still require to know how they are eventually to be got over the remaining inch—i.e., 2in. of compression in 7½in. length. On the other hand, if he refers to an armature of such a length as required in my motor—viz., 3in.—being made in laminations, he would require originally 80 discs 1-20th of an inch thick each, which, of course, will take up 4in. in length, and these must be squeezed down to 3in. by *means of a screw*. Under these conditions the iron would be compressed lengthways 25 per cent. I trust that no one but F. Walker, unless he has at hand an hydraulic press capable of exerting at least 1,000 tons pressure on the square inch, will attempt such a feat, and, assuming success to attend the effort, where would be the laminations?

After this unfortunate episode one is naturally surprised to see F. Walker in print again, and doing battle for this cross form of armature.

The only part of F. Walker's letter which is at all to the point is the first half of the second paragraph, when he, in trying to defend the armature in question, admits just what I stated—viz., that it is difficult for an amateur to wrap, and holds very little wire.

All who, therefore, contemplate making dynamos or motors, would do well to consider if F. Walker is suited to be their guide, when he himself gets into such terrible pitfalls.

The laminated armature I used, and from which I got such poor results, was that described by F. Walker in No. 1020.

**John E. Chaster,**
Electrical Engineer, Southport.

### VIOLINS.

[24042.]—I have read with much pleasure the two letters on this subject from a "Country Parson." I could have wished to have seen more precise dimensions of the drawings of the Strad. to which he refers, and if "Country Parson" does not object, I would be glad if he would send his address to me under cover to the Editor.

My object in writing on the subject of violins is not to elicit a long correspondence on the merits or distinguishing characteristics of noted old makers. I have at different times read a good deal on this subject, but when we read of this maker adopting a "high" model, or that maker being partial to a "flat" model, it conveys very little real information as to the nature of the curvature used. The curves of the back and belly, both lengthwise and crosswise, should be given in rectangular co-ordinates; the values of $x$ being equal distances on the horizontal line from neck to tail, and the values of $y$ giving the height of the curve at these points. If, as is usual, the entire length be divided into 72 parts, the value of $y$ should be given for every four of these parts. As regards the curve lengthwise, one series of measurements along the centre is sufficient; but for the curves crosswise, they should be taken at three places—across the middle and across the widest part of both top and bottom parts, the places where these lines cut the central line being carefully noted. The thickness of wood at some of the various points should be noted, though it need not be measured for every ordinate; probably for every eight parts of the central line and for every four parts of the cross lines would be sufficient.

A set of these tables for an Amati, a Stradivarius, a Guarnerius, or a Steiner, would enable anyone to plot out the curves and obtain correct templates from them, with a degree of exactitude not to be attained by any other method. Very few persons have the chance to copy a real first-class old violin; and if measurements of such a one exist, it is to be hoped that they will find a place in these pages.

But it may be asked, Why be at all the trouble to imitate exactly an old model, when the chances are that the fiddle will still prove worthless, since, as your correspondent very truly says, "Excellency in violins is not confined to any special form of arching or outline, or to any exact thickness of wood"? To this it may be answered, that while success may be reasonably hoped for by working with good wood on a good model, it is not likely to result from using good wood on a bad model. All that can be done for the violin has been done by the makers above named, and if we depart from the lines they have laid down, it must be a step backwards.

Although the curves in the best violins may not appear alike, it is not improbable that in the best instruments of any one maker, they may still belong to the same family of curves; and even in a "flat" and a "high" model it is not impossible for the curves to be of the same nature, though they differ so much in depth. A surface, the curvature of which is "gentle and easy, and free from any abrupt elevation," seems to indicate that the radius of the curve is governed by a certain law—unwritten, perhaps, but yet known to the eye of the artist. Those who have spent any time in tracing curves from their equations, will be aware how soon the eye is offended when an irregularity of curvature sets in, even in figures of very curious outline.

It would be a difficult, if not an impossible, task to strike out mechanically the governing curves of a violin back or belly, unless it can be proved that they belong to some well-known figure. This is why I have advocated their setting out in rectangular co-ordinates from some known good violins, by which the curve can, of course, be faithfully reproduced; and, also, it can be easily ascertained whether an equation can be deduced which will express the relation between the co-ordinates. I have previously said that the catenary curve seems best adapted for the violin arch, or it may approach nearer a parabola, for in this case these two curves would scarcely be distinguishable. I must, however, leave this and other matters for a subsequent letter. **Orderic Vital.**

[24043.]—In the appendix to Otto's book on "The Violin" there is described "A method for tracing a beautiful model for violin by means of a graduated perpendicular line," in which it is directed that the length of piece of wood intended for the back should be divided into 72 equal parts, in terms of which the description and diagrams are worked out therein. The rise for the back and belly is obtained by cutting a template of hard wood to the arc of a circle, the radius of which equals 216 parts, that is—three times the length of the body of the instrument. I do not know any book in which measurements of a "Strad" violin may be found; but if "Orderic Vital" has not seen the description above referred to, I shall be happy to lend him the book if he will advertise his address. I quite agree with him that age alone does not improve an instrument. An unplayed violin remains stationary as regards quality of tone. **War.**

## A NEW METHOD OF FOMING CRYSTAL MODELS BY PLAITING.

[24044.]—In this letter I propose to consider some of the various forms of "prisms." Fig. 5 is in a form ready for plaiting. As I find the meaning of prefixing — to a number is not quite clear, I substitute the word "under" for it. This is the *right rhombic prism*. It is bounded by six planes, two terminal rhombs, and four lateral planes. Angles of inclination of planes 60° and 120°. Plane angles of terminal rhombs 60° and 120°. Of lateral planes 90°. The tabular right rhombic prism of uric acid is a modification of this.

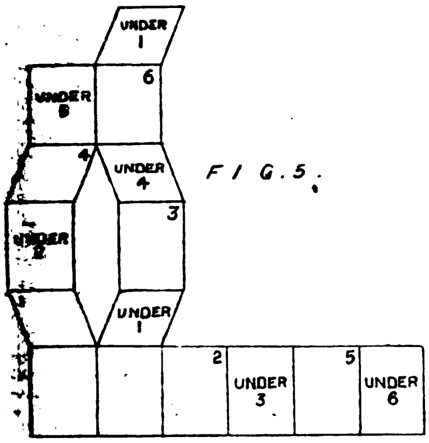

FIG. 5.

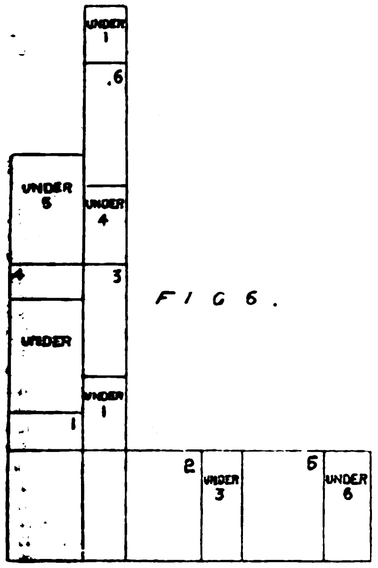

FIG. 6.

The *right rectangular prism* (obtained by plaiting Fig. 6) is bounded by six oblongs of three kinds. Angle of inclination of faces 90°. Plane angles 90°.

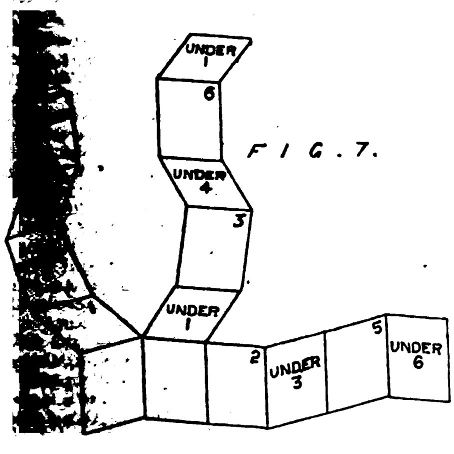

FIG. 7.

The *oblique rhombic prism* (Fig. 7) is the one in which the obliquity of terminal rhombs occurs in direction of their long diagonals. It has 6 faces, two similar and equal terminal rhombs, and four rhomboids. Angles of inclination of faces and plane angles vary. Project a spherical △ on three adjacent sides of crystal. If angles of inclination of planes be A, B, C, and the opposite sides *a*, *b*, *c*. Plane angles are given by the formula—

$$\sin.\ \frac{a}{2} = \left(\frac{-\cos.\ \delta \cos.\ (\delta - a)}{\sin.\ B \sin.\ c}\right)^{\frac{1}{2}}$$

The *oblique rectangular prism* (Fig. 8) is a modification of the last (see table).

Before proceeding with further examples, I had better add the analytical table—the basis of the structure. It will serve to give an outline of the subject. At present I have been explaining it in detail; in my next letter I will endeavour only to add to it the least amount of *necessary* explanation.

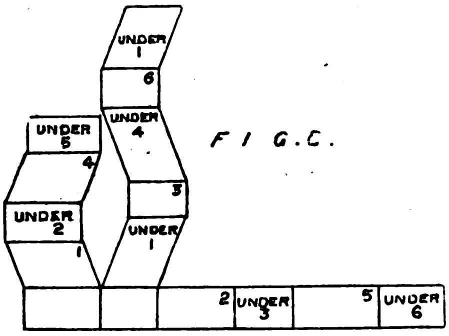

FIG. C.

**Analytical Table.**

| *Cube Simple*; planes entire. | Name of solid cube. |
|---|---|
| Two of its opposite planes brought nearer to, or farther from, each other | Right square prism. |
| Two of its opposite sides approximated | Right rhombic prism. |
| Lateral planes shortened | Right rhombic prism flattened. |
| Lateral edges replaced by rectangles | Right rectangular prism. |
| Elongated in direction of two solid opposite angles | Oblique rhombic prism I. |
| Lateral edges truncated | Oblique rectangular prism I. |
| Shortened in direction of two opposite solid angles | Oblique rectangular prism II.<br>Oblique rhombic prism II. |
| Solid angles deflected from perpendicular in two directions | Doubly oblique prism. |
| Elongated or shortened in direction of two opposite solid angles | Rhombohedron. |
| Plane angles of rhomb. = 101° 55′<br>,, ,, ,, = 60 and 120 } elongated | Acute rhombohedron. |
| ,, ,, ,, = 101 55 | Obtuse rhombohedron. |
| Each rhomb. replaced by scalene triangles | Scalenahedron. |
| ,, ,, two isosceles triangles | Double hexagonal pyramid. |
| + Rhombs. 60° and 120° form subside into | Laminated hexagon. |
| ,, ,, creased in short diagonals | Rectangular octahedron. |
| Planes of remaining octahedrons projected like those of Reg. Oct. | Right square octahedron. |
| Isosceles triangles 33° | Right square octahedron. |
| ,, ,, 70° | Obtuse square octahedron. |
| Scalene ,, 35, 63, 82 | Right rhombic octahedron. |
| Two isosceles triangles | Right rectangular octahedron. |
| Two scalene ,, 33, 60, 87; 38, 64, 78 | Oblique rhombic octahedron. |
| Two isosceles ,, and one scalene | Oblique rectangular octahedron. |
| Four dissimilar scalene | Doubly oblique octahedron. |
| + Rhombs. creased in long diagonals. | |
| Angles 60° and 120° | Tetrahedron. |
| ,, 117° 2′ 8″ | Trigonal dodecahedron. |

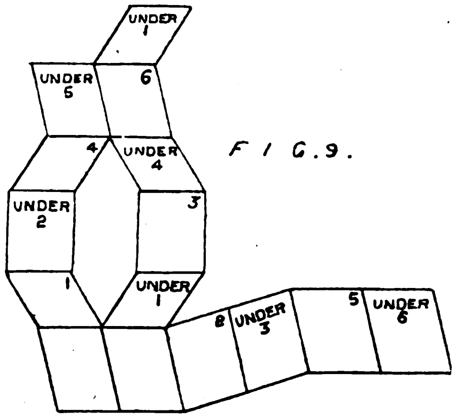

FIG. 9.

The square faces of a cube when projected on a plane surface in a definite order plait into a model of a cube; but other crystal forms, although bounded by planes altogether dissimilar, plait into their respective models in the same consecutive order as those of the cube. On pressing an elastic cube out of its perpendicular in various directions, its faces become transformed into various new shapes and models.

Before closing this letter I will, however, add Fig. 9, the second form of Oblique Rhombic Prisms, so that in another letter I can pass on to rhombohedrons. This prism is bounded by six planes—two rhombs and four rhomboids. For angles of inclinations of planes and plane angles see note on Fig. 7.

Park House, Tonbridge. E. A. Tindall.

## THE MOSAIC COSMOGONY.

[24045.]—In my humble opinion, the discussions which occur periodically in these columns with respect to the first chapter of Genesis are almost, if not altogether, useless; otherwise, I would suggest to our valued correspondent, Mr. Grey (23985), that the defender of the Mosaic cosmogony might take his stand on the nebular hypothesis, according to which the sun would necessarily come into existence last, when the difficulties regarding light and heat for the earth's flora and fauna which he points out would disappear. The antiquity of man is, of course, distinct from the question of his origin.

In structure the gorilla approaches nearest to man. Anatomically, I suppose, there is little difference; yet how great is even the physical contrast between man and the ape! Looking at the flat head of the gorilla, with ridges for the attachment of the biting muscles of the large and powerful jaws (man is the only creature that has a chin), and noting the reversed position of the arms and legs (the fore limbs of the gorilla corresponding as respects length to our legs, and *vice versâ*), I must confess that no amount of *verbal* demonstration will make the animal origin of man to me other than an unproved hypothesis. I am not questioning the law of evolution, only, like almost all other laws, it may have limits and exceptions.

As a matter of fact, so far as is yet known, a large number of animal and vegetable forms have appeared upon the earth suddenly—not generalised, but highly specialised forms. This may or may not be susceptible of explanation by imperfection of the geological record. In the mean time it is an assumption either way.

March 26. J. A.

## THE SIX DAYS OF CREATION.

[24046.]—It was not till after the middle or dark ages, when men were beginning to shake off the chains of religious oppression, which had held them in thrall so long, that they began to make observations in any degree free from the miracle-mongering of the Church. Even in those countries which later on accepted the reformed religion we find philosophers and men of science, either from educational bias, or influenced by circumstances, squaring their views to fit Biblical teachings. It is little more than a generation since that leading men of science were obliged, for truth's sake, to separate once, and for ever, the science of Biblical tradition from science founded on observed facts. Letter 24005, Mr. H. A. Wassell, belongs to the middle period, viz., that of squeezing the round man into the square hole. I, too, like Mr. H. A. Wassell, read the Bible in connection with science; but it was not long before I came to the conclusion that it was an absolute and sinful waste of time. I have studied the Bible for its own sake, and, unlike Mr. Wassell, find that a large portion consists of history and tradition. It is remarkable that many years ago Hugh Miller wrote a paper entitled "The Mosaic Vision of Creation," which tallies in every point with Mr. Wassell's remarks; or is it that his tallies with Hugh Miller's? In either case the observations contained therein are not in consonance with the geological record.

E. S. Hanson, F.G.S.E.

---

[24047.]—The scientific value of the narrative of Creation in Genesis may be determined by an investigation into the nature and character of the Hebrew deity. The ancient Hebrews, at different historical epochs, distinguished their God by three distinct appellations—namely, Elohim, which represented the heavens and the heavenly host; Jehovah, the summer; and Adonai (Adonis), the winter sun. In the 110th Psalm we read that "Jehovah said unto Adonai, sit thou at my right hand, until I make thine enemies thy footstool." Now Adonai, Baal, and Moloch signify "Lord," and were names which the Semitic nations gave to the sun as the supreme god, the king of heaven. "Being the source of life to the physical world, his departure from the upper hemisphere in winter was mourned as a temporary death; his return to it, being a new birth, was the occasion of rejoicing." The death of Adonai, at the winter solstice, was commemorated by impure rites by Eastern nations at midsummer, when the sun begins to descend among the wintry signs. Similar ceremonial was practised by the Hebrews in the Temple at Jerusalem (Ezekiel viii.; Kenrick's "Phœnicia," 308-311). The ancient Hebrews evidently worshipped Jehovah both as fire and as the sun. "The fire shall be burning upon the altar; it shall never go out" (Lev. vi. 13). It was as fire that Jehovah appeared—in the thunder and lightnings—on Sinai, the thunder being the voice and the lightning the arm of Jehovah (compare Isaiah xxx. 27-33). Upon the Ark, whose name is Jehovah (2 Samuel vi. 2), fire was kept continually burning, and thus Jehovah went before the Israelites, guiding them, in the wilderness. When removing from their encampments, their God went before them on the shoulders of the priesthood, as a pillar of cloud by day and a pillar of fire by night. When the Ark was removed from the Tabernacle to become the divine leader of Israel on the day's march, the priesthood, on placing it on their shoulders, uttered the invocation, "Rise up Jehovah, and let thine enemies be scattered; and let them that hate thee flee before thee." At the termination of the day's march, the priesthood solemnly solicited their solar God, whose symbol was fire, to "Return, O Jehovah, unto the ten thousand thousands of Israel." Malachi accordingly attributes righteousness to the sun: "Sun of righteousness arise with healing in his wings"; while in the Psalter the solar Jehovah is thus distinguished: "O Jehovah, my God, thou art very great; thou art clothed with honour and majesty. Who coverest thyself with light as with a garment: Who stretchest out the heavens like a curtain: Who layeth the beams of his chambers in the waters: Who maketh the clouds his chariot: Who walketh upon the wings of the wind (Ps. civ. 1—3). Jehovah rode upon a cherub, and did fly: yea, he did fly on the wings of the wind. Jehovah made darkness his secret place; his pavilion round about him were dark waters and thick clouds of the skies. At the brightness that was before him [sunrise] his thick clouds passed, hailstones and coals of fire (Ps. xviii. 10—12). Magnify him that rideth upon the heavens by his name Jehovah, and rejoice before him (Ps. lxviii. 4). Jehovah is King, and hath on glorious apparel; ever since the world began hath thy seat been prepared (Ps. xciii. 1-3). There went up a smoke out of Jehovah's nostrils, and fire out of his mouth devoured: coals were kindled by it (Ps. xvi. 8-9)." It has, therefore, become evident that the God of Israel, as of other nations of antiquity, was the solar deity, and accordingly the Creator of the universe was equally unknown to the Hebrew race as to the inhabitants of the earth at the close of the nineteenth century of the Christian era. The narrative of creation in Genesis is, therefore, of human origin, and consequently of no scientific value in relation to the origin of this planet or the epoch when man first appeared in the pre-historic history of the world. **W. M. Davidson.**

---

[24048.]—WITH regard to the fresco of the Zodiac at Denderah, recently referred to by one of your correspondents, the celebrated Egyptologist Champollion has proved that it belongs to the time of the Roman Empire. No conclusion can therefore be drawn from it as to the belief of the Israelites while in Egypt.

May I add, with the utmost possible respect for all who are taking part in this discussion, that it seems to me that the pages of a scientific magazine are hardly fitted for the examination of questions which demand a profound knowledge, not of mathematics or mechanics, but of Oriental languages and theological erudition? **R. D. S.**

---

## ETERNITY OF MATTER.

[24049.]—IN his proposition (letter 23997, p. 64) "A. W." assumes that "the material universe has been cooling as long as it has existed." This is not so. The sum of the energy of the material universe, transformable or otherwise, is constant and finite. Hence, in reply to E. G. Tindall (letter 24016), this finite energy, even if transformed into heat, could never have raised the material universe to an infinitely high temperature, for, even after all that energy had been so transformed, we can imagine a still higher temperature.

"R. W. B." seeks an explanation, as applied to heat only, in the transformation of other forms of energy into heat; but the sum of all energies being constant, such transformations cannot go on indefinitely. Yet, while the sum of all energies is, and, according to the law of the "conservation of the physical forces," must remain constant, the equilibrium of these energies must have been, at one time or other, greatly disturbed.

Practically this comes to the same as "A. W.'s" assumption, and makes his argument and conclusion an unanswerable dictum to those who, in order to escape the dilemma of miraculous creation, assume the eternity of matter.

We cannot conceive the existence of matter without energy, so to the "eternity of matter" has to be added the "eternity of energy."

But still more. Energy in a state of equilibrium is like steam applied simultaneously to both sides of the piston, and is practically equivalent to no energy at all. To convert such latent energy into potential energy, the believer in the "eternity of matter and the eternity of energy" must now call in some other unacknowledged or miraculous power to distribute the energy, and so disturb the equilibrium. In other words, to explain Nature as he finds it, he invokes the aid of three unknown powers, while others are satisfied to ascribe all at once to one omniscient, omnipotent, and supreme Being.

The material universe, as we see it, consists of hot bodies and cold bodies. The hot bodies are continually giving out their heat: this heat is not being lost, it is being absorbed by the colder bodies. This has not always been so—remembering that the sum total is constant and finite,—nor will it always continue to be so. Energy is being constantly degraded; work, motion, &c., are being constantly transformed into heat, which in turn is being dissipated to form one universal and uniform temperature throughout the whole material universe, and when the dead level has been attained—as it may already have been anteriorly in the distant past,—life and work will have become impossible. Therefore, as "A. W." proposes, "the present course of events called Nature has not always existed." **H. B. F.**

---

## THE ANTIQUITY OF MAN.

[24050.]—THE letters which have appeared for some weeks past upon this subject have all taken it for granted that man has existed through untold ages, and the earth itself also. Now surely this is a Q.E.D. As a working hypothesis I may believe many things as true, but not as an absolutely correct belief. I look upon the belief in a great antiquity and in evolution as I look upon the common definition of a mathematical point—that is, a means of marshalling one's ideas, but surely not to be sworn by. It would be a good thing if the "great antiquity" people would be a little less dogmatic, and allow that a man may have some brains who even held that the earth and its contents are all recent. **Geo. Bishop.**

Curate of St. Ann's, Nottingham.

---

## THE STATE OF MAN.

[24051.]—As "Dens," letter 24010, evidently believes there has been a universal deluge, I would refer him to "The Sacred Theory of the Earth," by Dr. T. Burnet, 1699, in which he will find much amusing and some instructive matter. I dissent entirely from the view put forth by "Dens"—that "the idea of a deluge, such as told in Genesis, has been ridiculed as an impossibility from the supposed want of water." That is *one* of the arguments advanced by *some* writers in refutation of the Deluge. I should be much obliged to "Dens" if he will send me six of those same chipped flints as are to be found in the valley of the Somme out of one of the cartloads from any of the chalk pits of Hertfordshire; I will gladly pay carriage. I understand "Dens" to mean the 6,400 years accepted by Sir John Lubbock, from a calculation made by M. Marlet, as referring to the age of the Swiss lake dwellings. But it is quite possible that hundreds of years elapsed during which these dwellings were occupied. Then, again, we have to take into consideration the great lapse of time that must have taken place to produce the degree of constructive ingenuity displayed by the builders of these lake dwellings. So that, as far as the original state of man is concerned, we are as wise as before. In letter 24013, as "Dens" condemns the Age of Ice, I advise him to read, if he has not already done so, Lyell's "Antiquity of Man," Croll's "Climate and Time," J. Geikie's "Great Ice Age," A. C. Ramsay's "Physical Geology and Geography of Great Britain," and also to keep beside him, for constant reading and reliable reference, A. Geikie's "Textbook of Geology"; all these authors treat very fully of the Glacial epoch. I also advise "Priam" (24014) to read the above books. I opine he uses the word "drift" to include boulder clay, glacial drift, and loess, which may be termed river drift. The general questions opened up by this corespondence are far too great, and of too much importance, to be disposed of in a summary manner, and those who have not read up the subject in a systematic manner, but who are interested in it, had better do so at once, and then they will be in a position to draw juster conclusions. Mere reading will be of little avail, unless they, like those who have studied these questions, combine their reading with personal observations of the operations of nature from the geologist's standpoint whose motto is "the present is the key to the past." The observations of James Hutton in Scotland, and William Smith in England—the fathers of geology—were held in quite as much ridicule in their day as the Glacial theory and some others are by their opponents at the present day; still the arguments they advanced, which were founded on observed facts, soon overthrew the hypothetical theories of the earth that had vexed men's minds so long. **E. S. Hanson, F.G.S.E.**

---

[24052.]—WHILE I agree with Mr. Wassell in the general scope of his remarks, I consider that it is not necessary to include the geological days or periods between the events referred to in Gen. i. 1, 2. McCausland, in his "Sermons on Stones," has shown the correspondence between these periods and the epochs of geology. The first day included the time before the nebulous matter was sufficiently cooled and consolidated to allow the existence of life on its surface. The semi-solid portion was "invisible," covered with vapour, and "unfurnished," "without form and void" (see Septuagint translation). At its close the darkness cleared away to some extent, and the influence of the sun sufficed for day to be distinguished from night. During the second era clouds were formed, rain fell, and trilobites and other crustacea inhabited the heated sea which then covered the earth. During the third period the Devonians and plants first grew. During the fourth day the clearer atmosphere enabled the sun to exert greater influence (in the poetical language of Moses, to "rule the day"), and the carboniferous flora flourished. In the fifth, from the Lias and Oolite to the close of the Chalk formation, air-breathing animals and reptiles ("great sea monsters") abounded. The sixth (Tertiary) was ushered in by the creation of the gigantic mammals and terminated by the appearance of man.

As the Mosaic account has been treated by some of your correspondents with scant courtesy, allow me to recommend to my fellow readers an inexpensive work, "Old Faiths in New Light" (Ward and Co.), which shows how admirably it was adapted to the early education of the human race. I do not agree with "Dens" that "palæolithic man is only a myth." Has he read "Dawkins's "Cave Dwellings"? May not the flint flakes have been the weapons of a people contemporary with the mammoth, &c., which passed away before the appearance of the Adamic race, to whose history alone the sacred narrative refers? See McCausland's "Adam and the Adamite," "The Genesis of the Earth and Man," by Reginald Poole, and to show that this is no novel notion, see a curious volume of sermons, "Men before Adam," 1656.

I will only intrude further on your valuable space by reminding your readers residing in London or the suburbs that a ticket of admission to the library at the British Museum may be obtained (gratis) on the recommendation of two householders, and that the obliging officials there are always ready to give every assistance to new readers as to the choice of books on every subject, and the means of finding them. **Otter.**

---

[24053.]—THE attempt to reconcile the Mosaic account of the Creation with modern scientific evidence is as futile as it would be to attempt to trace the theory of gravitation in the lore of ancient astrology. Discussions of this character are, unfortunately, always liable to jar on the sensitive nerves of some well-meaning people; but it is to be regretted that such individuals should, in order to support their religious convictions, make statements of a scientific character without first being certain of their truth. Thus, "J. H.," in letter 23927, says, "The fault lies with the scientists in not putting events in their proper form and order," and then, by way of putting things in better form, says, "That climatic changes were made by the *internal heat of the earth*, and *not by the sun*."

It would be interesting to learn how the variations of climate *could* be caused by internal heat, but until more light is thrown on the matter, I shall still believe that the sun has "just a leetle" to do with the climate. Then, after speaking of the first dawn and successively higher forms of life, "J. H." says "a glacial period put an end to it all by the world becoming frozen, desolate, and *dead*." Now, I do not think there is any scientific evidence to support this assertion. We know that over certain parts of the earth glacial periods of long duration have prevailed, but not over all the earth simultaneously. And even in Europe and North America, where the geological evidences of intense cold are most abundant, we have the authority of Lyell for believing that "quadrupeds of living, as well as extinct, species were common to pre-Glacial and post-Glacial times." Such a total destruction of life as "J. H." speaks of is not only not in accordance with geological teaching, but is quite reversed to it. It is now generally believed that animal life, since its first existence on earth, has been both continuous and progressive; and to believe, and spread the belief, that all life on earth recommenced after each glacial epoch is inaccurate and misleading.

Another way of attempting to reconcile the Mosaic account of the Creation with geology is to suppose that the six days were six periods, each of which might be thousands of years. There is not, so far as I know, any reason for the word day being regarded in any other than its usual signification; but if there were, it would not materially help to smooth the difficulties of comparison. If six long periods were meant, such as would allow time for the evolution of species as found in geological records, we should then have to believe that the earth existed and passed through the various stages comprised in three of these periods before the sun was in existence; and also that the trees of the field, and the grass and the herbs grew and bloomed in darkness and cold, for they were made in the period preceding that in which the lights were placed in the heavens.

It seems to me like "breaking a butterfly on a wheel" to try to make such reconciliation. The two theories, evolution and special creation, stand quite separate, one supported by a host of natural facts, the other supported only by the Mosaic statement. "O. J. L." and other thinkers may easily choose for themselves which theory to believe. **Silex Seadrif.**

## THE STATE OF MAN.

[24054.]—If your correspondents, "Priam" and "Memnon," will kindly read such an elementary book as Tomline's "Christian Theology," Vol. I. Part 1, they will probably see the shallowness of any arguments that object to Moses being the editor of the Pentateuch. **M. A.**

[24055.]—Some of your correspondents seem to have overlooked one circumstance in connection with the Scriptural dates which surely ought to be taken into account when we wish to determine such a question as whether Methuselah outlived the Deluge or not. It is this: The dates are only given, as it were, in round numbers; that is, only years are mentioned, in most instances, in giving the date of an event; but not months and days—as, age of Methuselah at birth of Lamech, 187 years; of Lamech at birth of Noah, 182; of Noah at Deluge, 600. Total 969 = age of Methuselah. Further on, however, in v. 11. ch. 7, it is said that: "In the six-hundredth year of the life of Noah, in the second month, in the seventeenth day of the month, all the fountains of the great deep were broken up," &c. Now, this certainly seems to imply that Noah, instead of being exactly 600 years old at time of Deluge, was only 599 years, 1 month, 16 days; and, according to this, Methuselah must certainly have outlived the Deluge, as "F.R.A.S." says. Perhaps, however, it will be impossible to come to any certain conclusion on this point without knowing how many months, if any, are to be added to or subtracted from the various ages; but, as the words stand, taking into account the correction in v. 11, it seems difficult to draw any other conclusion than that by "F.R.A.S."

Perhaps the views of our old friend, John Hampden, whatever may be thought of their scientific accuracy, are, at all events, more in accordance with Scripture than are those of many of our readers.

The remark of Mr. Ranyard in your last number (p. 55) that when strong language is used, "They will devote their time to criticising his language rather than to answering his arguments," is certainly deserving of all attention. He well describes the usual tactics of those who have a bad case to defend. Still, however, where great abuses exist they are generally denounced in strong language, nor is it by any means self-evident why the fact that the society in which there may be abuses is a scientific one, should be any reason, as some of your correspondents seem to think it ought, why its proceedings should be exempt from the kind of criticism which would be employed in the case of, say, a Worshipful Company of Bellows-menders; or, again, of those who habitually obstruct business in "another place." **W. G. P.**

[24056.]—In reply to "A. C." (24009), I remark that the reason given in Deuteronomy, *why* the Sabbath was to be kept, is *not* stated to be in addition to the reason given in Exodus, as he infers. To say that it is an addition, is simply to beg the question also. That the words given in Exodus were meant especially for Jews, and not for "man" in general, as the statements are preceded by the words, "I am the Lord thy God, which have brought thee out of the land of Egypt," seem quite clear; moreover, we do not know of any other people keeping the Sabbath for the reason alleged.

That the Sabbath was kept in Babylonia (from whence Abraham came) seems likely or certain; but there it seems to have had connection with the worship in some way, of the seven heavenly moving bodies, and not with the six days of Creation. No such custom was kept in Egypt, and anything which might occur at the Temple of Denderah is of so small value as regards ancient history, as it is a Ptolemaic and very late structure. Deuteronomy is considered by many to be a late book for many reasons, and was probably the book *found* in the temple in B C. 624, in the time of the pious Josiah, but which seem to have been previously unknown; for although in Deut. xxxi. 24, 26, it is said: "Take the book of the Law and put it in the side of the Ark of the Covenant," yet we know it was not there in Solomon's time, for in 1 Kings viii. 9, it says, "There was nothing in the Ark save the two tables of stone." As this Book of the Law was not known till 624 B.C., it is probable that it was written about that time, and its language, &c., seems more suitable to that period than to that of the escape from Egypt. "Numbers" seems more ancient, but probably was written *after* Saul's victory over Agag, as it says, xxiv. 7, "And his King shall be higher than Agag." "Leviticus" must have been written after, and not before, the Israelitish occupation of Palestine, as it says at xviii. 24, 27, 28, "Defile not yourselves in any of these things . . . . that the land vomit not you out, *as it vomited forth* the nations which were *before you*."

The difficulty also occurs in Deut. ii. 12, when it says, "The Horims also dwelt in Seir before time; but the children of Esau succeeded them, when they had destroyed them from before them, and dwelt in their stead, as Israel *did unto* the land of his possession, which the Lord gave unto them." Moses surely would have said as "Israel will do," not "did," as they had *not done it* in his time.

The word "Kirjatharba" is interesting in more ways than "A. C." mentions. We read in Genesis xxiii. 2, "And Sarah died in Kirjatharba; the same is Hebron." And at xxxv. 27, "And Jacob came unto the city of Arba, which is Hebron." These statements must have been written *after* the establishment of the Hebrew cities and Hebrew names, and not before it.

The slight difference of language mentioned by "A. C." (who is sure to have given his best cases) between parts of the Pentateuch and the later books, only proves what I do not deny—namely, that some difference of date exists between the books; but does *not* explain away the difficulty I raised, which is the unreasonableness of supposing that from 70 people of all ages, and their descendants who resided many hundred years in Egypt, an immense slave population of 3,000,000 should issue forth into the deserts, speaking and understanding a pure and well-developed Canaanitish language, just the same as their descendants used in Canaan about 1,000 years afterwards.

There was no reason why they should have preserved the Canaanitish tongue, as they hated the Canaanites, and their Ancestor came from Ur of the Chaldees. When we find them in real historic time in Canaan, we find them using a language related to that of other tribes evidently allied to them; but we know that the Semitic Phœnicians, who were Canaanites, and were related to the Jews slightly, used a language that is not the same as Hebrew, as we know it, but may have been like what Isaac used.

The name "Hebrew" is, I believe, peculiar to the Jews, so that the words attributed to Joseph in Genesis xl. 15, "I was stolen from the land of the Hebrews," simply proves the late origin of the book, as there were but 70 Hebrews then in Canaan, and no one can have called it their land, as no one would know what land was meant by that name under any circumstances but themselves.

I am afraid the names mentioned by "A. C." only go towards proving that the Hebrew tongue was allied to, perhaps derived from, Canaanitish sources—not that pure Hebrew was spoken by Moses's generation. It is perfectly true that our division of the Bible into chapters and verses is modern; but its division into books is not, therefore I fail to see why the last chapter should be transferred to the book of Joshua, which is not part of the Pentateuch at all.

In reply to his objection respecting the references to the Kings of Israel, I must say that kings could not be looked upon with pride or satisfaction by Jacob or Moses, if they were in harmony with Samuel. Indeed, in the face of 1 Samuel viii. 7, where it is said, "The Lord said unto Samuel, Hearken unto the voice of the people in all they say unto thee, for they have not rejected thee, but they *have rejected me* that I should not reign over them," and as the people demanded a king, Samuel gave them one very unwillingly, and after eloquently describing what an unpleasant person a king might be expected to be.

This incident makes the quotation from Genesis by "A. C." appear to be written after the kingly time, and increases the meaning I put on the passages I quoted from Gen. xxxvi. 31. If Moses had written the book, the passage would probably run thus: "These are the kings that ruled over Edom before the Children of Israel entered Canaan," and not "before there reigned any king over the Children of Israel."

I would like to know what Mr. Wassell (24005) understands by "chaos"? or the passage, "The earth was without form and void"? Do they include the development of the stratified rocks with their fossils? Do they permit the growth of trees and plants? Do they allow of the existence of millions of highly organised animals with eyes, &c.? as, if so, had we not better expunge such misleading terms? They were certainly not so understood by any one till recently—till science had proved that the world existed and was filled with plants and animals for countless ages.

I would also like his opinion on the words in Exodus which assert that the heavens and the earth, and also all that in them is were made in six days, as they appear as if written to exclude Mr. Wassell's plan, and to exclude it in words of remarkable clearness and decision.

As there was no one in Eden while the world was being made, it is hard to know why the necessarily erroneous views a man would take if stationed there should be written down for all posterity by Omnipotence as truth.

Allow me to correct a clerical error in my last, as in it I used the name "Manetho" instead of "Menes." Manetho is the earliest Egyptian historian, and speaks of Menes, the earliest king. **Memnon.**

[We must apply "the closure." The letters to hand this week are so numerous that it is impossible to find space for a tenth of them, and each week the subject widens. We regret that in one or two instances correspondents have not shown due consideration for the opinions of others who may not yet have attained to the clearer perception of truth of which they deem themselves assured, and that on the other side an undue nervousness as to the effect of such controversies on religion has been manifested. We think with the writer of one of the ablest of the unprinted letters which lies before us as we write, that "there are no more powerful and insidious enemies of the Bible than those who persist in reading actual history and modern science into its poetry and allegories," and we fear, with the writer, "such a relapse into a blank stupid atheism as may well appal the stoutest heart," as the result of such an endeavour.—Ed.]

## DIAMOND FOR CUTTING TOOLS.

[24057.]—For all the purposes of drilling, turning, and cutting hard steel, I prefer splinters of the crystal or gem diamond. These can generally be selected with suitable sharp edges or points. The black diamond, or "carbonado," came into the market about 35 years ago, or it was at that period that I procured my first example. It was then to be had at 12s. per carat. It has risen since to double that price. I prefer this to the gem for turning glass, as, from an apparent porosity, it retains a rough corner for a longer time, for, after some use as a glass-turning tool, both the gem splinters and the edges of the carbonado get blunt and polished, and the latter being more brittle, a fragment can sometimes be broken off to furnish a fresh edge, or rather corner. I have seen the carbonado in irregular pieces, one nearly the size of a hazel nut, which looked as if it had been broken off something yet bigger; and I am acquainted with a turning tool consisting of a piece of carbonado that cost nearly £11. It is mounted in a long handle, so as to be held to the shoulder.

What is the origin or source of this mysterious but exceedingly useful material? In one lot that I bought many years ago from a dealer in Hatton-garden, there was a piece nearly a perfect sphere, two-tenths of an inch in diameter. The exterior has the appearance of minute crystalisation, or is covered with glittering laminæ, not to be broken off. The weight of the nodule is 1·6 carat, and it forms such an interesting subject for the microscope that I never had the heart to pound it up for lapidary purposes, though it is rather a costly object, its value being 38s. 6d. Are any of the largest nodules invested with a crystaline coat of this description? If so, they would resemble some samples of pyrites? Can any of our readers give a description of the matrix or native bed in which this useful material is found, but which I suspect is held as a monopoly for maintaining a high price. **F. H. Wenham.**

## ORDNANCE MAPS—PROJECTION, &c.

[24058.]—I am glad to have it in my power to give a reply to the query of "F.R.A.S." on this subject, and as I am indebted to the courtesy of the Director-General of the Ordnance Survey for the information, it is, of course, authentic.

I can strongly support the wish of "F.R.A.S." for the issue of a convenient hand-book relating to these maps, as, though there exists a large volume containing information on certain points, such a the mode of adjusting the differences due to errors in taking the levels (by the method of least squares), together with lists of the bench marks, and such like, yet no simple manual has ever been issued. The issue of the maps themselves is also susceptible of improvement. When an ordinary firm finds a large demand for a work, they issue a fresh edition; but the Ordnance Department goes on the opposite principle, and keeps on raising the price till the demand is checked, so that the price is often more than doubled in a very short time.

The following is given in almost the exact form in which I received it, and has not before appeared in print, so far as I know:—

The projection used for the "one-inch" map of England is that employed by Casimir de Thury for a map of France in the last century, and is simply a meridional plane chart.

The distances measured on the prime meridian, and perpendicular thereto, have their true spheroidal proportion on the map. The maximum variation of scale at any point varies with the secant of the distance from the prime meridian; but this variation is not sensible within the limits of a sheet of the map, and is much less than is due to the expansion and contraction of the paper. The marginal lines of the sheets are parallel, and perpendicular to the prime meridian. The projection of the "one-inch" map of Scotland is slightly different, the distances on the prime meridian (4° of west longitude) are in their true proportion, and also the lengths of arcs of longitude (not the perpendiculars to the prime meridian, as in England). In effect, this is a modification of the conical projection, so that theoretically the areas of the surfaces are correctly represented. The distortion of distances is different, but not very dissimilar, to that of the projection used for England.

A. S. L.

### MINERAL-OIL LAMPS.

[24059.]—In your columns of the 27th inst. a letter signed J. Hughes expresses grave dissent from Sir Frederick Abel's opinion that metal "reservoirs" for the oil are preferable to those of glass or earthenware, because, says J. Hughes, metal being a good conductor of heat, rapidly heats the oil; whereas glass, china, and the like being non-conductors of heat, the oil remains cool.

Now, in differing with J. Hughes, my reasons shall be stated. Please to bear in mind the meaning of the two terms as follows:—1. A conductor of heat conveys it away. 2. A non-conductor of heat retains it.

Of two lamps of the same size and shape, let us assume all things identical, such as oil, wick, burner, chimney, flame, &c.; but one lamp shall have its reservoir of copper, a good conductor, and the other of earthenware, a non-conductor.

Of course, the heat generated by each of the burners will be the same. Will J. Hughes kindly state what becomes of it? Is it conveyed away or retained?

His letter finishes thus: "But I am convinced that far more danger would accrue from the general heating of the oil in metal containers than from the few occasional fractures."

Now, the fact is, that lamps of tin, the "reservoirs" of which are about 2½in. by 2in. by 1¼in. deep, costing 6d., are in use by the million in this country, also in Europe generally, and probably over all parts of the world.

**J. D. Shakespear**, A.M.Inst.C.E.
Institution of Civil Engineers, 25, Great
George-street, S.W., March 30.

### THE SKRIVANOW BATTERY.

[24060.]—Is there likely to be any truth in that paragraph which appears on page 54? It was also given by an electrical paper, and I wrote to an eminent firm, who manufacture such forms, to ask if these results had really been achieved. Their answer did not give much encouragement.

But if there is anything in it, would not the Grove battery be superseded for the electrical lantern? And, by the way, how would the "Sun" incandescent arc-lamp answer for this purpose, instead of the Duboscq? Has it been tried?

**Antares.**

**Transit of Jupiter's Third Satellite.**—ERRATUM.—In Mr. Ellis's letter on p. 78, eighth line, "II." should be "Jupiter," the mistake having arisen through the use of the sign for that planet.

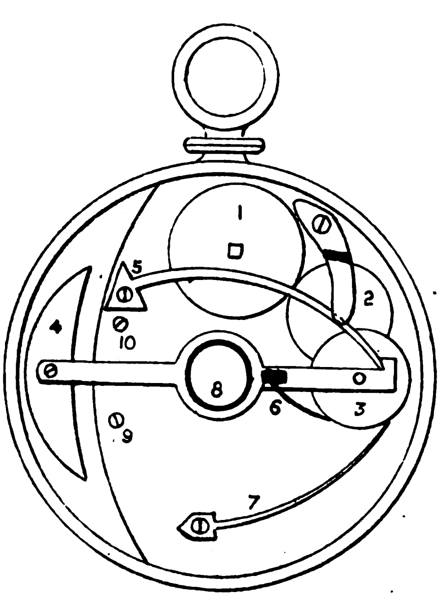
A TELEPHONE ticket, at half a franc, has been issued, the holder of which is entitled at any of the Paris post-offices to hold five minutes' conversation with persons in any other post-office, or at any of the Telephone Company's stations. The system came into operation on Sunday last. The Telephone Company offers, at the same rate, conversations at any of its eleven stations with persons at any other station or at the residence of any of its subscribers.

## REPLIES TO QUERIES.

**** In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[55827.]—**Gravity 'Scapewheels.**—I am sorry I cannot give Mr. Floyd any definite information about the use of aluminium bronze for the 'scapewheels of large gravity escapement clocks, beyond my own opinion that it is well adapted for them. But Messrs. Gillett and Co. (no longer Gillett and Bland) use phosphor bronze for them, which seems to do very well, and I believe is cheaper than the other. It has the advantage over steel for large wheels that it can be cast, while steel ones have to be cut out of a plate. For regulation size, up to about 5in. diam. in a four-legged wheel, I have never seen anything but steel used, because lightness is desirable.—EDM. BECKETT.

[55930.]—**Watch Winding.**—As requested by "M.M.I.Sc.S.," I send the following sketch.



1 is wheel fastened on to end of barrel-arbor on square under dial; 2 is an intermediate pitching into No. 1, and into pinion under 3; 3 is a ratchet-wheel with the finest possible teeth; 4 is the pendulum working up and down by the action of walking; 5 is spring to keep it evenly balanced between two screws 9 and 10; 6 is spring attached to pendulum working into ratchet-wheel; 7 is spring fastened to plate, working also into wheel; 8 is a space to free the hour wheel. The above is patented under the name of Loehr's.—ANNIE.

[55870.]—**Optics with the Lantern.**—The reversal of the sodium line is always a rather ticklish experiment. When I was working it out, I used a jet lent me by a friend for some time, of great power; some time after that, when I attempted it in just the same way with an average jet, I found considerable difficulty. The essentials appear to be, a very brilliant light for the ordinary spectrum, sufficient to *overpower* the sodium light; and then a good gush of sodium vapour, from quite a good piece of metal, *not too hot*. The latter condition is best attended to by varying the position (perpendicularly) of the gush of sodium vapour; and hence the boxed-in arrangement described by "S." is a drawback to success. The closer the slit and sodium can be got to the lime the better; as the further off they are, the greater *proportionate* brilliance has the sodium flame on the screen; whereas we want it the least possible. I have lately been endeavouring to devise details which may make the result certain; but they are not finally tested yet, and more pressing experiments must hinder for at least a week or two. As the subject is not of very general interest, if "S." will send his address, through the Editor, as soon as I have time to perfect them I will communicate with him, or if in London in person. Meantime he may derive a hint from the description last week of Mr. Cleminshaw's experiments, though the results as exhibited would by no means satisfy me; the condensation of limelight on the slit is, however, sound, and the principle of my own arrangements. Lastly, in reference to the letter (23978) of "E. R. P.," whose lantern arrangement seems very ingenious and useful, it will be observed that his position for a prism, described as "close in front" of the *lantern* objective, is practically just close to the crossing-point. However, there is no reason why anyone should not place a prism or any other apparatus precisely wherever he finds it best; though if "S." is in London, I should like to get to the bottom of his experience.—L. WRIGHT.

[55933.]—**Old Locomotives.**—In the *Mechanics' Magazine* for Jan. 28, 1832, there is an account of some experiments "recently made" on the Canterbury and Whitstable railway, in the form of a letter, which bears the date of Jan. 7, 1832. The line, it appears, ran out of Canterbury up a gradient through a tunnel until it reached a summit, whence it proceeded fairly level to a falling gradient followed by a level run of a mile, and then a descending curve into Whitstable, the distance being six miles. Stationary engines were placed at each end of the summit level; but the level run of a mile was worked by "one locomotive engine, on Stephenson's principle, of 10 horse-power." This engine appears to have gone at the rate of 4·61 miles per hour going to Whitstable, and at 8 miles an hour on the return journey. The name of the engine is not mentioned, although the writer took the times and distances himself. He signs himself "F. W.," and writes from Ely-place. It is evident, therefore, that a locomotive engine was running on the Canterbury-Whitstable line at the very beginning of 1832, and tolerably obvious that it must have been there in 1831. As to what explanation can be given of the statement referred to, it is only that which is patent to all who have had occasion to examine historical evidences, that the writer was stating only what he believed to be true. Old volumes of the *Mechanics' Magazine* can occasionally be picked up at second-hand bookstalls; they are worth all the money usually asked for them.—NUN. DOR.

[55961.]—**Horse-power of Engines.**—The method of calculating the horse-power of steam-engines has been frequently given, and "Side Lever" can hardly expect that anyone will sit down and work out a sum for him which will be of no use to anyone else.—ESSAR.

[55967.]—**Shading.**—Would this querist explain what it is he wants to know? If he means colouring or tinting drawings, surely the answer will be, In the usual way.—ESSAR.

[55970.]—**Soluble Essence of Ginger.**—"Nemo" asks how to make the insoluble resin and volatile oil found in essence of ginger miscible in water. It cannot be done, or, to be more accurate, no one has yet done it. The soluble essences are prepared by precipitating and filtering out the substances which will not mix with water.—NUN. DOR.

[56025.]—**Trueing Grindstone.**—In my reply, p. 40, I did not refer to "Nun. Dor.," and did not know anything of the accusation he says has been made against him. Has he not found a cap, tried it on, and found it to fit, and appropriated it? If "Nun. Dor." will refer to Mr. Williams's question and subsequent explanation, he will see that Mr. Williams, when he first wrote, knew nothing about what he now says is the fact—viz., that the invention in question was not protected by patent. I agree with "Nun. Dor." that, notwithstanding the words of the prohibitory clause in a patent, a man may make a patented machine for the purpose of seeing whether it can be improved; but Mr. Williams was not (in his letter) asking for information for the purpose of making experiments.—Z. Y. X.

[56055.]—**Diazo-Salicylic Acid Sulphate.**—To "C. W. S."—This is obtained from salicylic acid. The process is somewhat complicated, it is true, and requires a practical acquaintance with the preparation of many of the compounds in organic chemistry. Salicylic acid is produced by several methods. 1st. Oil of winter green (*Gaultheria procumbens*) distilled with potash. 2nd. From the flowers of *Spiræa ullmaria*. The flowers are exhausted with ether, or the water distilled from them, with frequent cohabation, is shaken up with ether; the ethereal solution is distilled, and the residue is treated with water which dissolves salicylic acid and tannin. The aqueous solution is neutralised with carbonate of soda, evaporated and distilled with hydrochloric acid. The watery distillate, slowly evaporated, yields colourless crystals of salicylic acid. 3rd. Salicylic acid is now prepared on the large scale by synthesis from phenol. Sodium phenylate is first prepared by dissolving phenol (better known as the white crystalline carbolic acid) in caustic soda, and then passing carbon dioxide into the dry salt, which is slowly heated up to 220° to 250° (Centigrade). The sodium salicylate thus formed is distilled with hydrochloric acid, as given in the previous method. Now, diazo-salicylic acid sulphate is the double acid of diazo-salicylic acid and sulphuric acid, and is prepared by dissolving diazo-salicylic acid in sulphuric acid (not too strong); the solution, on cooling, deposits the substance you require—viz., diazo-salicylic acid sulphate. Diazo-salicylic acid is prepared by passing nitrous acid into an alcoholic solution of the hydrochloride of amidosalicylic acid, when slender needles are formed, which may be recrystallised from hot alcohol, but are decomposed by long boiling, with evolution of nitrogen. Hydrochloride of amidosalicylic acid is produced by the action of tin and hydrochloric acid on nitrosalicylic acid. The liquid obtained solidifies to a crystalline pulp, consisting of a compound of stannous chloride, with the hydrochloride of amidosalicylic acid, which, when dissolved in water, decomposed with sulphuretted hydrogen, and evaporated in a stream of that gas, yields colourless crystals of the hydrochloride of amidosalicylic acid. This acid is insol. in cold water and alcohol. Its hot, aqueous solution exposed to the air quickly decomposes. Nitro-salicylic acid is produced by acting on salicylic acid by means of boiling nitric acid, and washing the resulting crystals in cold water. Hence to obtain diazo-salicylic acid sulphate, you require to form the compounds as hereinbefore described in the following order: 1st, Salicylic acid; 2nd, nitro-salicylic acid; 3rd, hydrochloride of amidosalicylic acid; 4th, diazo-salicylic acid, and 5th, the compound you require. Your query states you have "dialysed for it": this would lead me to suppose the "diazo" has misled you. Dialysis is distinctly a method of separating crystalloids from colloids, and is in no way connected with what you require. Try Woolley and Sons, 69, Market-street, Manchester, as I can often obtain from them what I cannot in London.—JOHN E. CHASTER.

[56064.] — **Troublesome Battery.** — Many thanks to "C. D. R." and Mr. J. Kean for their kind answers to my query of the above. I have done to my battery what both those gentlemen suggested, and up till now I find them going on satisfactorily. Why I ask if old charge would do in new pots—I have some which have given up working, and thought new pots were wanted. 2, I want to make a coil for strong shocks. I have been reading back numbers, and cannot find where to connect the handles, and by drawing out the brass tube as a regulator, does the core come out also? If Mr. J. Kean or some other kind reader would give me the best way to proceed, I should be greatly obliged. Would a piece of ¾ iron pipe cased outside with brass do for the regulator? Now for the battery. I have a glass cell, two plates of carbon 5¼ long, 1⅜in. wide, and a zinc the same size, with six ounces of bichromate of potash to a pint and a half of water. Would that do to work the coil? Please say how much primary and secondary will be wanted.—J. PARSONS.

[56081.] — **Baffled.** — To "A. S. T. E."—I beg to thank "A. S. T. E." for his reply to my query, and to inform him that I cannot use a pivoted needle on account of the E.M.F. being only just sufficient to move the astatic one. I have tried the platinum and carbon contact he recommends with the astatic system, but with less favourable results than with the platinum alone, as I find the two require a considerable amount of pressure before they will act. I wish to say, however, that I regard the sticking of the contact pin as an advantage rather than an evil, as I propose to apply a contact breaker to the needle, which will only be allowed about a quarter of an inch play. Leaving out the carbon, if I moisten the pin with a little sulphuric acid, its action is nearly perfect. Could he kindly suggest any other material for the pin, since sticking is no obstacle? I should mention that I used common gas carbon in the experiment above referred to.—BAFFLED.

[56086.] — **Optical Formulæ — Nobert's Ruling Machine.**—I am glad my friend "Ascalon" has called attention to the formula in Ross paper on page 445, last volume. Ross annexes the two small letters *o* and *c* to the capital R to denote the *outside* and *contact* surfaces of the flint, and as the letter *c* is afterwards introduced into the calculation, some confusion is liable to arise. The italic *f* is a misprint or mistake for F″, and in the denominator the value *c* is apparently involved in its own formula. Perhaps I had better alter the nomenclature by making R′ denote the outer radius, *r′* the inner radius, using a capital C instead of a small *c*, and a small *c* instead of *c′*. Then the formula should stand as follows:—

$$R' = (1 + q')\,F'a' \ : \ r' = \frac{1 + q'}{q'}\,F'a'$$

Next for the auxiliary values:—

$$b = \frac{a'}{1 + a'}\ ;\ C = \frac{F''}{r'}\ ;\ c = \frac{(1 + a')\,F''q'}{a'F'' - R'}$$

And, finally, for the spheric aberration:—

$$p = \left\{ \begin{array}{l} \dfrac{(C + q')^2}{(a'C - q')^2} \cdot \dfrac{C + (a' + 2)\,q'}{C(a'c + a + 1)^2} + \\ \dfrac{(c + 1)^2}{(bc + 1)^2} \cdot \dfrac{(c + 2 - b)\,q'}{c} \end{array} \right\} \frac{a\,s}{q' + 1}$$

The reader who wishes to correct the formula on p. 445 must recollect that wherever C appears in the present formula, *c* should appear in the original one; and wherever *c* occurs in the above, *c′* should be found in the other referred to. The sign of *b* should be "minus" not "plus," as there printed. My series of articles on the object-glass is now finished, that is, until something new, or old, turns up. If "Ascalon" or any other reader chances to come across anything more respecting Gauss' o Hastings' formula, I hope we shall hear of it. The account of Nobert's ruling machine, which appears in the report of the R. M. S. meeting, will have interested a large circle of readers. I earnestly hope that when the full illustrated account appears in the *Journal* of the Society, it will be reproduced in these columns. The description of so unique a contrivance will specially interest "our" American friends.—ORDERIC VITAL.

56097.]—**Conics.**—The tangent to a conic has for equation $y = \frac{x}{n} + a\,n$, where *n* is the co-tangent of its inclination to the axis, and the intersection of the tangents corresponding with $n_2$ and $n_3$ is $x_1 = a\,n_2 n_3$, $y_1 = a\,(n_2 + n_3)$, with similar expressions for the intersections with the $n_1$ tangent; but the area of the triangle with vertices at $(x_1\,y_1)$, $(x_2\,y_2)$, $(x_3\,y_3)$ is—

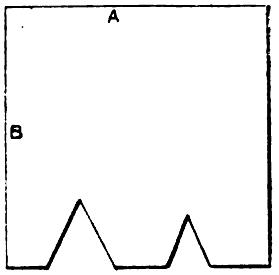
$$\tfrac{1}{2}\,[x_1\,(y_2 - y_3) + x_2\,(y_3 - y_1) + x_3\,(y_1 - y_2)],$$

or, in this case—

$$\tfrac{1}{2}\,a^2\,[n_2 n_3\,(n_2 - n_3) + n_3 n_1\,(n_3 - n_1) + n_1 n_2\,(n_1 - n_2)].$$

which becomes $a^2 n^3$ on writing *n* for the differences $n_1 - n_2$, and $n_2 - n_3$, which are equal since the co-tangents are in A.P.—R. E. B.

[56098.]—**Grinding V Tools**—The best angle for V tools for screw-cutting is the angle of 55 degrees. You can make a gauge from sketch below, which will serve for grinding and setting the tool to. If you are cutting outside threads, place A side of gauge against the work, and set tool to one of the V's, according to size of tool. If inside threads, place B side against face of work and set tool as before.—VALETTA.



[56106.]—**Gun-Barrel Browning.**—I have already replied to this query. I should not have done so had I known that "Armourer" intended to come forward, who has used the process more extensively than I have done. My own practice has been limited to developing the striations and contortions in faggotted and scrap-iron forgings, and also replenishing the pattern of the barrels of my own shooting-irons. Having met with a similar difficulty as that mentioned by "A. Z.," I can perhaps give him a useful hint. The distinctness of the twist or pattern developed in a gun-barrel much depends upon the metal used. If a mixture of iron and steel, there is not much difficulty, but if the barrel is forged entirely of steel, or of strips of metal alike in quality, the pattern will not be so marked. In this case the barrel must be "pickled"—that is, immersed in a trough of water acidulated with sulphuric acid for an hour or so; a galvanic action takes place, the softer parts being corroded by the acid from the positive influence of the hard portions. Of course, the muzzles of the barrels should be well corked up, and the breech blocks (if any) coated with wax. When the twist appears plain enough, remove the barrels, rinse them, and at once give the first coat of bronzing liquor. Do not rub this on, but give one light stroke with the sponge. After laying by from one to three hours (according to the dampness of the weather or place) pour a kettle of boiling water over every part of the barrel, and while hot scratch-brush it all over. Using the scratch-brush on a barrel the least degree damp is fatal to the process. Repeat this operation till the colour is dark enough. It is sometimes difficult to get the admired purple striation on some barrels with any number of repetitions. In this case, having gone as far as possible after the last brushing, give the barrel a wash with a dilute solution of perchloride of platinum.—F. H. WENHAM.

[56122.]—**Small Brace.**—To "INVICTA."—I want brace for hand, suitable for model-making, if you will oblige me.—S. B.

[56122.]—**Small Brace.**—If this querist will look on page 547, Vol. XXXV., he will see illustrations of several small braces which will probably suit his purpose. There is also a very good article attached on Riveting China, &c., by "Alfojoe." I often wish "Alfojoe" would come to our aid in several little matters that remain unanswered from week to week.—ARVONIA.

[56126.]—**Chemistry Exam., London University.**—"Londoniensis" must study the following: O, H, C, N, Cl, Br, T, Fl, S, P, Si, $CO_2$, CO, oxides and acids of N, $NH_3$, $C_2H_4$, $CH_4$, $H_2SO_3$, $H_2SO_4$, $H_2S$, HCl, $H_3PO_4$, $PH_3$, Si; air, flame, combustion, fuel, water, combination, nature of acids, salts, bases, symbols. I do not consider Gill's a fit book; Roscoe (Macmillan, 4s. 6d.) is the best. I think it is too bad that "Londoniensis" should be snubbed as he has been, and I hope that the communications of his advisers will be placed in the index with the A.'s (Advice to a Grandmother); otherwise readers may be misled. I often think it a pity that contributors to "Ours" do not take Montaigne for precept, and our old friend "Sigma," for example. I am sure all readers of "Ours" will cordially agree with latter part of 55982, page 85. If "Londoniensis" thinks I can give him any further information, let him write again to "E. M.," or to—H, 74, Charrington-street, N.W.

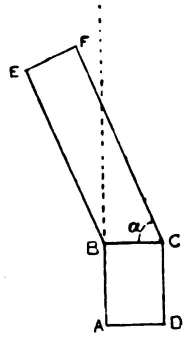
[56132.]—**Cutting Pipes.**—I fear that Mr. Geo. A. Walton must have been rather hurried in his reply to this query, as his reply is "a' vrang thegither," as an old Scotch acquaintance would put it. In such a case as that given in "M. B. M.'s" sketch (where C F terminates on line A B produced)—

$$BE = \frac{(CF)^2 - (BC)^2}{CF}$$

Taking dimensions given in sketch—

$$BE = \frac{625 - 36}{25} = 23{\cdot}56\text{ft.}$$

In a case where C F does not terminate in line A B produced, length of B E can be easily found when C F, B C, and angle B C F (= *a*) are known. B E = (C F − B C . cos. *a*). Value of "cos. *a*" can be found from a table of sines or of cosines. Is it not rather unusual to have part "A B C D square"? The cross-section of part E B C F will be, not a circle, but an ellipse (i.e., if pipe A B C D be of circular cross-section). Should not line B C bisect angle A B E? If so, then value of B E in this case also is (C F − B C . cos. B C F). I presume that "M. B. M." understands how to arrive at development of joint B C?—JNO. M. ADAMS.



[56135.] — **Value of Gas Liquor.** — Both "Stud. Inst. C.E." and R. Hannen have important errors in their replies to this query. Liquor of 5° Twaddel does not contain 2·55 per cent., but 2·25 of ammonia, and Scotch liquor of 5° Twaddel frequently contains only 1·52 per cent., and thus 3,810 gallons are required to make one ton of sulphate of ammonia. The hydrometer does not show the value. It would be some comfort to those at present experiencing such heavy losses in this trade to find the price had gone up to £15 to £20 per ton. I know a very superior lot could not be sold last week at £11 nett in buyers' bags!—$NH_3$.

[56142.]—**Wheatstone Bridge.**—Use a tangent galvanometer, and have a number of various resistances loose, or in a box; insert your unknown resistance (R) in the circuit of your galvanometer and battery, regulating your battery power so that the deflection does not exceed 60°—between 30° and 45° is best; deflections beyond 60° are very unreliable. Note the deflection carefully. Take out your unknown R, and insert your R coils until you have the same deflection; then the last R will be equal to your unknown R. Use only Daniell cells. —J. K.

[56143.]—**Hermit Crabs.**—As "Yesallaw" has given his hermit crabs proper food, I am of opinion that the cause of their untimely death is in the improper construction or management of his aquarium. The ordinary globe aquarium sold in shops is about the worst that could possibly be devised; being contracted at the mouth, it does not allow the water to become properly aërated, a sine quâ non in all aquariums, and for marine aquariums it is particularly objectionable, as there is not sufficient area on the bottom for crabs, &c., to live in health. The simplest suitable form of aquarium is an ordinary fern-glass inverted and placed on a turned pedestal; for a marine aquarium, the hollow at the bottom should be filled with sand, and a rockery might be made in the middle; coral is imitated by coating coal-cinders with melted resin mixed with Venetian red, and finishing off with a penknife. As to management, the water should be occasionally drawn off by a siphon, and fresh water substituted, and should be daily aërated either by lifting cupfuls and pouring back from a height, or by drawing off and violently squirting back by a syringe. It is very advantageous to have some seaweed in an aquarium; but care must be taken that what is put in does not decay. As a general rule the most beautiful specimens will not grow even in the most favourable circumstances—and a few periwinkles might be put in, as they eat the green fungus which adheres to the sides. For crabs a rockery should be built rising above the water, as apart from the fact that crabs are great climbers, they are amphibious, and like occasionally to come out of the water, and when feeding them do not take the food out of the shell, but break the shell and throw it in. Remove plants with wooden tongs, and when removing fishes do not draw the greater part of the water and make grabs at the fish, but stir the water round with your arm, causing a strong current, which the fish are unable to swim in, when they can be captured with ease. The aquarium should not be placed where it is exposed to the sun's rays all day, or the water will soon get too hot for anything to live in it, and if there is much dust or dirt about, a glass cover should be put on, raised, however, to allow air to enter, but even this will require to be removed at times to allow proper ventilation.—James M'Cash Govan.

[56146.]—**Spiral Springs.**—Having got the steel to the right shape, heat to a cherry red in a bright charcoal fire and plunge in cold water; then get a lot of brass or copper filings, or small turnings, and put them into a metal vessel on a slow fire; by putting the springs in this you can watch the temper, and you will be sure of having them tempered evenly all over. I think a light blue would be best, but I am not quite sure.—$H_2S$.

[56152.]—**Tempering Steel.**—To "Uncas."—If you read our friend "Essar's" letter (23962) on page 57, last week's number, you will find that he goes on hot about tempering medicine. He may be able to do it without, but all of us are not. The question then naturally arises, How can we do it? We must try something else. Take 1oz. of common washing soda, and 1oz. saltpetre; dissolve in half gallon of cold water; heat to a cherry red and put the tools in it as far as you want hardened, and let them cool; but keep from soap.—G. T. D. C. E.

[56153.]—**Test for Oils.**—Really the conscience of some querists is very elastic. Here "W. E. P." asks for information which would take a number of the "E. M." to satisfactorily answer, and then I question whether he would be able to state definitely whether a given sample of oil was pure or not. I would recommend "W. E. P." to secure Spon's "Encyclopædia of Industrial Arts," and carefully study the sections on "Oils," "Soaps," "Candles," and practise testing samples of oils; practice is the only thing which can make anyone a good oil tester. —George H. Hurst, Salford.

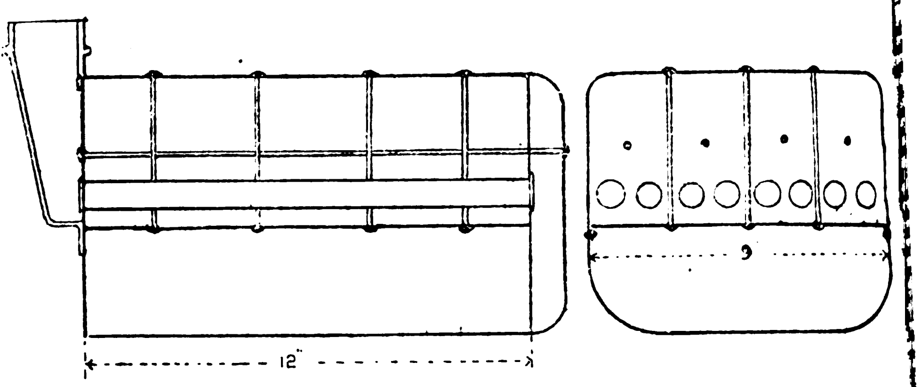
[56156.]—**Chemical Action of Bichromate Battery.**—In the bichromate battery the sulphuric acid combines with the zinc to form sulphate of zinc and hydrogen; this hydrogen, some of the sulphuric acid, and some bichromate, combine to form water and chrome alum, which is a double sulphate of potassium and chromium, thus—

$$H_2SO_4 + Zn = ZnSO_4 + H_2$$

$$3H_2+4H_2SO_4+K_2Cr_2O_7=K_2SO_4 \;.\; Cr_2 3SO_4+7H_2O$$

It is owing to the presence of the double salt of potassium and chromium that the solution becomes black. I am not aware that the refuse liquor is of any practical use.—$H_2S$.

[56159.]—**Model Engine—Boiler and Boat.**—Boiler for your engine should be a horizontal one; but with engines of such size you will want a very powerful boiler. The best illustration I can give you of such a boiler is that of one I designed for a friend in New York some time since, where the engine power was a trifle more than yours, it being a pair of cylinders 1½in. by 2½in. The boiler should be made from sheet copper 3/32in. thick, and of the sizes shown, the surfaces being principally flat ones, so that the boiler could be kept below the deck. It would require staying. This was done as shown by means of four horizontal and 12 vertical stays, made from 3/16in. brass wire, with the ends only well annealed so as to rivet over well. The water space was traversed by eight ¼in. brass tubes, also well annealed on the ends only, which were well turned over on the tube plates. The return at the end and the smokebox were as described on page 326 of last Vol., and the steam dome was ultimately fitted to the flat top of boiler, the dimentions being 3in. diam. and 3in. high. This was a casting in brass. The spirit lamp was also of peculiar form, it being of the siphon class, and with flat parallel wicks running longitudinally. Length of each wick was 3in., number of wicks, 6; size of funnel, 2in. diam. But I would advise an oval funnel 2¼in. on the longest axis and 1½in. on the minor axis. This was subsequently fitted with an improvement in the general appearance. Owing to the tubes being kept well down, the water level admitted of considerable variations of level, allowing a fall of no less than 1½in. without decreasing the heating surface of the boiler. The steaming power is very good, giving a large volume of steam of a moderate pressure. In actual use this boiler carries about 10lb. to 12lb. pressure, which is ample for a model engine. Now, as to the boat, that I would make, say, 6ft. long, 12in. beam, and 8in. deep under the deck. In your case, with such a tall pair of engines, I would make the depth over 9in. or 9½in., and then cover the remaining height of engine by either an engine-hatch or a saloon. The engines are, in fact, too high; but having got them, I should not certainly condemn them. Screw may be 5in. to 6in. diam., and about 6in. pitch. I should prefer three blades.—Invicta.



[56160.]—**Planing Machine.**—The only machines which I know of where such a condition is fulfilled are those driven with links or cranks.—J. H.

[56161.]—**Telescope.**—If by "making" the instrument you mean grinding the lenses as well as fitting them up, an amateur would experience great difficulty indeed; but if the lenses are already procured, it is simply a matter of suitable tubes, careful adjustment, and a respectable stand. For an object-glass 3½in. aperture, 4ft. focus, to magnify 125, a single lens of a trifle less than ⅜in. focus should be applied, or an optician will send you a compound eyepiece, giving better results, at a moderate cost. You omit to state whether your o.g. is achromatic or not. If not, it is hardly worth a compound eyepiece.—Arthur Mee.

[56170.]—**Microscopical.**—I am glad to see in the pages of your highly useful and interesting journal, a discussion on the relative advantages of the binocular and monocular forms of microscope. I think it can be rendered of great practical utility, not only to students and workers with the microscope, but also to the manufacturers of that instrument. The facts to be discussed, and the problems to be solved, are, I take it, these: Is not the binocular form less wearing for the eyesight, especially in the case of prolonged observations; or can the monocular form be so employed as to obviate all danger of the sort? Secondly, does not the binocular afford a more complete and definite idea of the object than it is possible to obtain with the monocular? Thirdly, could not the tubes of both forms be much shortened, and the mountings and accessories reduced in size, thereby effecting a great reduction in price? I know that the Germans, who have made the greatest discoveries with the microscope, employ almost invariably the monocular form; but that is no reason why we should not employ the binocular if it proves to be more convenient and less hurtful to the eyes. We should make our work, however, productive of really scientific and practical results, which may increase our knowledge of the operations of nature, such as the splendid researches of the Rev. Mr. Dallinger, instead of the utterly useless examination of diatom markings.—R. D. R.

[56175.]—**Books on Herbal Medicine.**—"W. M." will find the following suitable for him:—Gerarde's "Historie of Plants," Parkinson's "Herbal," Hill's "Herbal," Culpeper's "Herbal," Robinson's "Herbal," Dr. Coffin's "Family Guide," Skelton's "Family Guide," Stevens's "Family Guide," Fox's "Family Guide." American: Dr. Beach's "Reformed Practice of Medicine," Dr. King's "Dispensatory." If he desire to recognise the herbs while growing, the illustrated herbals will be of great service to him, as also would be a journey or two with a herb gatherer. If I can assist "W. M.," I shall be pleased to do so.—C. Lakin, L.R.C.P.

[56177.]—**Earthenware.**—Mr. Haydock can make a white glazing by slipping his ware, previous to putting on the glazing, with clay that will give a white glaze when the ware is in a stiff state fit to take the slip. Will give Mr. Haydock all the information I can if he will write to my address.—S. Arlidge, Weedon, Northampton.

[56178.]—**Gum Juniper.**—The best solvents are alcohol and ether; "Koila" should try these. Gum juniper is not completely soluble in any other liquids.—George H. Hurst, Salford.

[56180.]—**Martini-Henry Rifle.**—1st. With a hammer and punch knock out the split pin (it looks like a screw at first sight) which holds the breech-block in place. The punch should be a shade smaller than the s.p.—any bit of iron, even a blunt nail, will do for a punch. My way is: Knock the s.p. about three parts out, then pull out with pincers. Now depress lever, and the breechblock will somewhat spring up, when you can lift it out. 2nd. On the left side of the body (that large piece of iron which on the one side is screwed on to the barrel, and on the other is made fast to the butt, is called the body), and pressing against the end of the indicator, observe a small screw, with a little piece, arch fashion, cut out of its head, turn that screw till the arch forces the end of indicator, then push out indicator Then draw out the lever, the tumbler comes with it. As gentlemen of a certain land might say, the other pins are screws. You have only to unscrew them, and the parts come away very easily. 3rd. Go back to the B.B. You will see in the back end of the B.B. a large screw and a small one by the side of it similar to that which keeps the indicator in place. Turn the small screw as you did in the case of the indicator. Then unscrew and take out the large screw (which is called a stop nut), and the main spring and striker will fall out. Putting the action together: When you take out the B.B., and before you remove any of the other parts, look into the body, move the lever and trigger, and observe how those parts act and sit. With two exceptions you have only to observe the order in which you took the action to pieces to replace the parts again. The two exceptions are important: 1st. Notice that the slot or slit in the striker is tapered, so that it is longer on the one side than the other. In putting it back into the breech-block, you need pay no attention, just drop it in anyhow; but when you get in your stop-nut and its keeper, screw in place; then, with your screwdriver, turn the striker round till its longer slot agrees, or is even, with the slot in the B.B. Now assuming that you have your guard, trigger, lever, tumbler, indicator, and extractor in place, lay in the B.B.; put your finger on the trigger as in firing, press it back, and with the other fingers grasp the lever, place the ball or back part of the left hand on the extreme back part of the B.B. Now, while you press back the trigger, you must work the lever backwards and forwards, and at the same time press on the back part of the B.B. with some force with the left hand; the B.B. will fall into place. All the motions should be done together. I may remark that getting the B.B. into its place is the only trouble in a M.-H.R. action at first and to an amateur; but all that trouble goes after having performed the work three or four times. The Lubricant.—I think you are mistaken in thinking that the lubricant used is thicker than oil. Most likely, when you got your rifle, whether from a gunmaker or Government stores, there was some thick composition on, to prevent rust for the time. Well, I cannot tell you what gunmakers use or recommend; but the only oil used for the Service rifles (Army) from about 1859 to 1880—beyond 1880 I can't speak—is Rangoon oil. I don't think it is a well-known oil. It is rather dear, being 8s. a gallon; but it goes a long way, and one of its virtues is, it never clogs. It leaves no dirt behind. From 14 or 15 years' experience, I can strongly recommend it. For an oil it is extremely thin. I have had a little experience in purchasing Rangoon oil; and in asking for it at one druggist's shop I was simply laughed at, and put down as one on whom a First of April trick was being played. Doubtless it is now better known. Let me add that no rifle in use at the present requires less oil than the M.H. Indeed, it is a great mistake to over-oil any piece of machinery.—Armourer.

[56182].—**Sweet-making.**—If this querist sends a penny stamp to J. Willson, Church-street, West Hartlepool, inquiring for book on this, he will get what he requires, very cheap.—Arvonia.

[56183.]—**Force and Motion.**—The tension on the rope is only that of one horse. The steam on the cylinder is the same per square inch as on the piston; but, of course, if the area of one is greater than that of the other, the total pressure on one will be greater than on the other.—$H_2S$.

[56185.]—**Astro. O.G.'s.**—"T. P." will find a great deal of information relative to fluid lenses in back volumes of the Mechanic, a perusal of which will likely convince him of the disappointment occasioned by their non-permanence. The old astronomers did the best they could with non-achromatic o.g.'s by making them of great length in comparison with their aperture, thus obtaining considerable magnifying power whilst keeping down the aberration. Reproductions of old views of these unwieldy refractors appear in Flammarion's "Terres du Ciel," Newcomb's "Astronomy," and elsewhere.—Arthur Mee.

[56185.]—**Astro. O.G.'s.**—As the result of my own experience many years ago, I should strongly dissuade "T. P." from attempting the construction of fluid lenses. The trouble would be very great, and the chance of success very questionable. The old astronomers avoided the imperfections of the common uncorrected o.g., by making its focal length so great in proportion to its aperture that the errors were reduced within bearable limits. But the inevitable result was the employment of most cumbrous and inconvenient instruments; an o.g. of only 3in. aperture, requiring a tube of about 30ft. It is most honourable to their perseverance that with such appliances they should have discovered as much as they did.—T. W. Webb.

[56186.]—**Gum for Micro. Slides.**—The mucilage used for postage stamps is made by dissolving 2oz. dextrine in 1oz. acetic acid, diluted with 5oz. water. When the dextrine has dissolved, add 1oz. alcohol to the solution.—Mikros.

[56196.]—**Gas-holder.**—Several plans are in vogue for the purpose. One I have used when putting plates all round a 36ft. holder was broad tape soaked in boiled linseed oil and rolled into a ball for use as required. This is placed between the joints as they are put in position, and the rivets well hammered up.—Arvonia.

[56200.]—**What is a Diamond Carat?**—Jackson, in his "Modern Metrology," gives the following:—

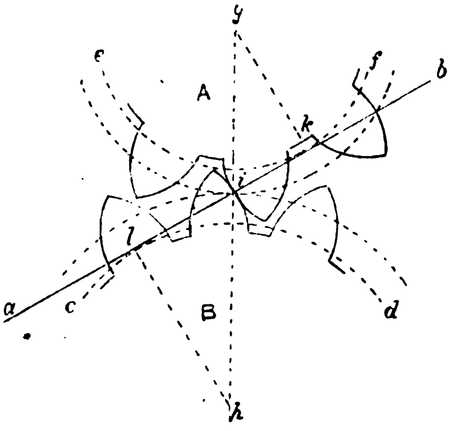
| | Grains. | Mils. |
|---|---|---|
| English diamond carat .. | 3·168 | 7·250 |
| " Pearl carat...... | 3·200 | 7·323 |
| German diamond carat .. | 3·171 | 7·257 |
| French ditto .......... | 3·177 | 7·270 |
| Dutch ditto ............ | 3·165 | 7·243 |
| Austrian ditto .......... | 3·181 | 7·280 |
| Egyptian ditto .......... | 2·959 | 6·772 |
| Persian ditto ............ | 3·232 | 7·397 |

The "carat" is connected with the term used for expressing the quality of gold and silver alloys in this way—that the old "mark" was divided into twenty-four real carats or weight units.—N. E. Child.

[56205.]—**Tennis-court.**—The size of a court I have, and which I let during the visiting season, is made of grass kept well rolled and level, and grass very short. The measurement of court is as follows: Outside mark, 78ft. by 36ft.; inside length is 42ft. width, less the 36ft. by 4½ft. each side. A chalk mark also running through centre from end to end. The net being put across reduces each central square to 21ft. You will find a lot of trouble in making one of ashes, as the turf all wants removing, and soil taken out to a foot depth at least, and filled in with any rough stones, &c., on which weeds may not grow. Then, when properly levelled, put on cinders, rough first, then finer, and finish by rolling with heavy roller, levelling with spirit level, &c.—Arvonia.

[56206.]—**Teeth of Wheels.**—The form of teeth in your sketch is weak and of bad design. I recommend you to get a book called the "Work Manager's Handbook," by Hutton, wherein you will find a simple method of drawing wheel teeth. I have had some wheels made by Hutton's method, and find they work sweetly, and the teeth are very neat and extremely strong. The book is published by Crosby Lockwood and Co., Ludgate-hill. I notice in this book, among a long list of alloys, one or two to stand acids that would suit "Enquirer," No. 56041, and the book is crammed with valuable practical information for Engineers.—Abbey Mills.

[56206.]—**Teeth of Wheels.**—I know of no teeth made with only one sweep, except the involute form, and they are struck as follows:—In the wheels A and B in the annexed figure, the path of contact of the teeth is represented by the diagonal line *a*, *b*, and the amount of its obliquity determines the amount of obliquity in the tooth-flanks. This line cuts two circles, *c d*, and *e f*, which represent the working depth of the teeth of the two wheels. In striking out it is necessary to assume either a definite depth for one of these lines below the reputed pitch line of its wheel, or to fix an angle for the line *a b*, relatively to the line of the centres of the wheels *g h*, and either will furnish a suitable base of operations. If we assume the line of working depth *c d*, we must draw the diagonal *a b*, cutting the reputed pitch circles at *i*, and prolong it, as shown in the figure. Then a line *g k*, dropped from the centre *g*, at right angles to *a b*, gives at its point of intersection the radius of the base line *e f*. If, however, we start with the line *a b*, our working depth of tooth will be given by the intersections of the normals *g k*, and *h l*. Then the teeth are pitched, not on the reputed pitch lines, but on the base lines, and their curves are struck, either by a needle-point driven into the edge of a straight edge, whose edge is rolled around the base line, or by an approximate radius whose length is equal to about one-fourth the distance from *i* to *l*, or from *i* to *k*, for their respective wheels. Two or three experiments may have to be made before a good tooth is obtained, since the degree of obliquity of the line *a b* depends upon the relative sizes of the wheels. Too much obliquity will cause the teeth to fall short of their proper working depth, and throw the strain on the shafts at too great an angle, while too little will needlessly diminish the length of teeth.—J. H.



[56211.]—**Water Pressure.**—The question does not admit of an accurate answer, as the coefficients for any particular cases must be obtained by experiment. As a rule, however, proceed thus: Ascertain the velocity of flow, and calculate through what height a body must fall to gain that velocity, then multiply by a coefficient for the particular case. The following case is given by Haswell: A fire-engine discharges 14 cubic feet per minute through a ·75in. pipe. Find vertical height of projection—14 × 1728 ÷ ·4417 (area of pipe) ÷ 12 (ins. in feet) ÷ 60 (seconds) = 76·07ft. velocity. But velocity of stream from a vessel is $\frac{2}{3}$ that due to its head ∴ 76·07 × $\frac{3}{2}$ = 114·1ft. By experiment in this case, coefficient is 67 ∴ height of projection is 65·04ft. The most suitable exit pipes are long, slightly convergent cones.—Geo. A. Walton.

[56212.]—**Dr. Johnson's Opinion of Mechanics.**—Dr. Johnson meant that mechanics were persons in a lowly position. The word itself means something pertaining to machines, and therefore low as compared with mind, the intellect. Walker gives—"Mechanic: a manufacturer, a low workman;" and the adjective as "mean, servile; constructed by the laws of mechanics." Shakespeare, "Antonio and Cleopatra," V. 2, says:—

> "Mechanick slaves,
> With greasy aprons, rules, and hammers."

And "Coriolanus," V. 3:—

> "Do not bid me
> Dismiss my soldiers, or capitulate
> Again with Rome's mechanicks."

It was undoubtedly a term of disparagement. Both "low" and "vulgar" have acquired a different signification since Walker's time, for he expressly says that "vulgarism" was not in any dictionary he had examined; but he inserted it in his own as sufficiently authorised both in writing and conversation.—N. E. Child.

[56213.]—**Common Red Ware.**—For common red ware it requires nothing but good common brick clay well prepared either by washing or grinding, by means of a roller mill, then well dubbed or passed through a pug-mill. We used to pass our slip clay, for slipping, through a fine lawn sieve, the clay to be mixed with water in a pan to about the consistency of cream, then passed through the sieve into an outer pan by gently tapping the top of the sieve with a bit of stick, to make it pass through quicker. Don't want a slip kiln for common ware; would not pay. The large jowels are thrown on the wheel down to a penny pan, and when dry the lead or glaze is put on by means of a brush, or slipped on, according to the nature of clay, then set in the kiln and fired. No biscuiting for common ware: that belongs to our better kind of ware, such as yellow dishes, teacups, basins, pitchers, &c., which are fired in jaggers—jaggers not required in common red ware. Will give any-one further information so far as I know.—S. Arlidge.

[56221.]—**Blue Shadow.**—The greenish-blue colour in the first case, and the decided blue in the second, noticed by J. Gayler, are the complementary hues of the two colours respectively, and are always evoked by the sensorium, and seen by the eye under given conditions, these being an adjacent grey, of which a shadow consists. An analogous experiment will show similar results in a satisfactory way. Puncture the bottom of a half-ounce pill box with a small needle, place a sheet of white paper on a table by gaslight—now look through the small needle-hole at the paper with the other eye closed, a small round white disc will be seen. On opening the other eye the disc will appear of a beautiful cobalt blue colour. Blue being the complement of yellow, the kind of light emited by gas flame.—John Gorham.

[56222.]—**Testing Gauges.**—Weight so arranged as in sketch would give a pressure of somewhat more than 20lb. on the circular inch, as area of piston rod must be deducted from that of piston in order to find effective area causing pressure. Same remark applies to finding pressure per square inch. (If cylinder B were a square inch in area, it would be $1\frac{1}{8}$in. full (1·128) in diameter, not $1\frac{3}{16}$). If you give diam. of piston rod, there will be no difficulty in determining what weights you ought to employ to produce any desired pressure per square (or circular) inch. If opening A were at the other side of piston, and weight acted in the opposite direction (say by means of a cross-head), diam. of rod need not be regarded. A large proportion of the loss from friction could be obviated by arranging the cylinder vertically, and hanging weights directly to end of rod (or to cross-head); but weight of piston and rod would have to be regarded as part of the compressing weight.—Jno. M. Adams.

[56222.]—**Testing Pressure Gauges.**—"Jack's" first supposition is correct—namely, that the pressure on the piston and on the gauge is the same per unit of area. The area of a circle $1\frac{3}{16}$ diam. is more than 1 sq. inch. A circle of 1 sq. inch area would have a diam. of 1·12838. Does it not occur to "Jack" that if his cylinder were vertical, and the nose A had a right angle elbow on it, that he would avoid the friction of the pulley, and would work his experiments easier. I would also suggest that the area of the piston is immaterial if he calibrates his instrument thus: Attach about a yard of glass tube to A, and notice the level of water in it when the weight E is just sufficient to overcome the friction of the instrument. Then find what additional weight will raise the level of water 2·24ft. This weight will correspond to a pressure of 1lb. to the sq. inch. Then any given multiple of this weight will correspond to a similar pressure per sq. inch. So much for instrument proposed; but there are simpler and better ways of obtaining good results.—Geo. A. Walton.

[56233.]—**Intensity Coil.**—The best way to find the size of condenser for an intensity coil is by experiment. Try three square feet of tinfoil with a 1½ pint bichromate cell, connecting condenser temporarily, and adding more sheets of tinfoil, one at a time, as long as beneficial results are observed. It is not easy to say what length of spark you may expect, as, from the dimensions you have given, it will depend very much on the space between primary and secondary caused by insulation, and on the thorough insulation of the secondary layers. A rule which is commonly followed, and which does not always hold good, is that with sufficient battery power a spark ought to be produced at the rate of an inch per mile of secondary; but no such result has been got, even from coils of unusually large size.—Bobadil.

[56239.]—**Filtering Acids.**—Asbestos filtering cloth—or, if more convenient, the fibre—is what "F. G. S." requires.—$NH_3$.

[56239.]—**Filtering Acids.**—If your acid does not attack cotton goods, and the filtrate is not loaded with the precipitate, a filter press, such as may be obtained from Messrs. Needham and Kite, of Vauxhall, London, or of almost any engineer in the Staffordshire Potteries, might possibly suit your purpose.—Pottery Tech.

[56243.]—**Fuses for Projectiles.**—In answer to "Ex-Garrison Gunner," I must say that the service fuses have been having a lively time of it since he left the regiment. The chief changes are as follows:—The 5, 9, and 20-seconds Boxer time fuses are superseded by a 15-second and 30-second fuse, on the same principle, but with several powder channels (eight in the 30-second fuse), and marked for boring spirally in tenths and half-tenths. The "E." time fuse is extinct. In its place we have the "Fuse Time and Concussion, Armstrong, medium," which is very similar in appearance to the E time fuse, but can be used as a concussion fuse if necessary. The "C." time fuse is modified and now called the "B.L. plain." There is a "Sensitive Percussion Fuse" for use with the 7-pounder guns and howitzers. Its name denotes its character. The R.L. percussion fuse still remains. There is a "Delay Action Fuse," used for base of battering shell 64-pounder (for the 64-pounder R.M.L. gun has risen to the dignity of having a Palliser shell!). This fuse has a percussion action which, on impact, ignites a column of fuse composition, which burns long enough to give the shell time to bury itself in masonry, &c., before bursting. At present, the fuse is only used with 64-pounder shells, and it seems to answer well. These are the chief changes I can remember; but if "Ex-Garrison Gunner" wants more information I shall be happy to look it up for him when I have time. He will know what a job it is hunt up an item in "Changes of War Material" for the last five years, as the Government is too economical to publish new manuals of artillery. I have been employed extra-regimentally for the past two years, so perhaps may have missed out some new fuses, but I think that the above are the principal changes.—Garrison Gunner.

[56244.]—**Skrivanoff Battery.**—Make a paste of the precipitate got by boiling one part mercury oxide and four parts ammonium chloride. Boil for about three hours in a glass vessel; wash and dry the precipitate thoroughly, and mix it with a solution of chloride of zinc, and a few drops of sulphuric acid. Having made the paste, add a little common salt, in the proportion of three parts of salt to ten of paste, cover zinc and carbon plates with any kind of thick cloth, or with a good pad of blotting-paper, dipping them for a few seconds (after covering) into a solution of chloride of zinc and common salt. Apply the paste to one plate not much thicker than the edge of a new sixpence, and lay the other on it. You will thus have a plate of carbon and a plate of zinc, each in a porous envelope, with the paste between which is the exciting element.—Bobadil.

[56247.]—**Photographing Engravings and Plans.**—Put the plan or engraving in the sunlight in such a position that it does not reflect the light, and so make an indistinct photograph; also you must, of course, take care that no shadows fall across it. No variation will be necessary in the developer; but take care to put in enough ammonium bromide to get all the detail distinct. With these precautions you ought to succeed all right; far from being more difficult to photograph engravings than views, it is generally easier. Take care not to overexpose the plate, or you will have such a thin picture that the engraving is almost invisible.—R. A. R. Bennett.

[56248.]—**Turning Cast Iron.**—First of all, give your hard cast-iron one or two good coats of turpentine, then turn with an ordinary front roughing-out tool with a very little rake on it, making the tool as hard as the steel will stand; the turpentine works wonders on the hard scale, and it is a wrinkle worth knowing.—Little John.

[56248.]—**Turning Cast Iron.**—Use a crutch tool tempered to a very light straw colour. Take a deep cut and a slow feed, and thus get beneath the crust at a single cut. When the tool dulls take it to the grindstone again. If the tool dulls at once, throw away the casting and go to another foundry. Finally, if this is impracticable, place the casting in a fire and keep it bright red for two or three hours and place in a large box of sifted ashes to cool.—Geo. A. Walton.

[56250.]—**Engine Making at Home.**—No; not in all details. All working centres, lengths of rods, &c., should be halved exactly, but thicknesses and diameters would vary. If you are going to make an engine on this type, the best way will be to proprose queries of parts in detail, and I will answer them. In reference to the cylinder on p. 24 of Vol. XLI., where the thickness is given as $\frac{5}{16}$in., if the bore were reduced to 1⅜in. the metal thickness should not be reduced proportionally, but should be ¼in. if in iron, or $\frac{3}{16}$in. in brass; and this, of course, as I there explained, solely from considerations of convenience in construction. The flanges should be not less than 3in. diameter, which is also more than half 5⅜in., what you have to consider there being sufficiency of bolt room, and their thickness should not be less than ¼in. when finished. The ports will not vary as the diameter, but as the area of the cylinder, and, using the same rule, will be 2·0 × ·055 = ·1100 area, or, say, ¼in. by $\frac{5}{32}$in., or less than half those in the 3¼in. cylinder. I should put them ¼in. by $\frac{3}{16}$in. On the steam-chest face, and on the feet for bolting down you must see that you get sufficient bolt room; $\frac{3}{16}$in. bolts will be a suitable size, and their heads will measure ⅝in. across the angles, so you want room for these to turn, and about ¼in. metal beyond the outer edges of their holes. In reference to the mahogany bed: By all means adopt it if you do not feel competent to tackle the metal one; a block of mahogany of, say, 2½in. or 3in. thickness, having a moulding worked around its edges and polished would look well in contrast with bright metal work. Have sufficient width, so that the screws or bolts by which you fasten the parts thereon shall not split it out at the edges, and see that the crank shaft is long enough to carry the flywheel clear of its edge. The bosses for the guide bars would be best made of brass or wrought iron, furnished with a central screwed pin to run into the wood. In so small an engine omit the force-pump at the side of the cylinder, and make one of shorter stroke worked by an eccentric.—J. H.

[56251.]—**Australian Vertebrates.**—Mr. Gould's "The Mammals of Australia," 3 vols., folio, coloured plates. It is a magnificent work; but, unfortunately for weak purses, the price is also magnificent—forty guineas, or thereabouts. See various articles in the new edition of "Encyclopædia Britannica."—R. C. D.

[56253.]—**Alizarine Oil.**—"A. C. M." has not given quite sufficient data to satisfactorily answer this question. The mode of using alizarine in printing varies so much at different works, and the character of the oil used also varies, that one cannot say definitely what is best unless acquainted with the details of each particular case. Supposing "A. C. M." works thus: 1, Prints on colour; 2, ages and dungs; 3, dyes with alizarine and oil; 4, oil and steams; 5, wash and soaps. Then I should not recommend him to add anything to the oil in No. 4. He might add acetate of lime at 21° F., in the proportion of $\frac{1}{10}$th of the alizarine used; or he may use a little tin crystals with the soap in No. 5—say, about 2oz. to 3lb. of soap.—George H. Hurst, Salford.

[56261.]—**Selenite.**—"F. E." will probably know it better by its ordinary name of "Plaster of Paris." It is calcium sulphate, and all the "permanent hardness" of water is due to the presence of this salt.—R. A. R. Bennett.

[56261.]—**Selenite.**—This is a pure, natural variety of calcium sulphate ($CaSO_4$). It is a suitable substance to add to soft water for brewing purposes, as it is soluble in 500 times its own weight of water. The hardness imparted to the water is just the thing for brewing. The amount of hardness imparted to water by dissolving 2lb. of selenite in 25 barrels is 15·5 degrees. Calculated thus, 25 barrels contain: 25 × 36 = 900 gallons; 2lb. = 14,000 grains; $\frac{14{,}000}{900} = 15{\cdot}5$ grains per gallon = degrees of hardness for $CaSO_4$ in water.—George H. Hurst, Salford.

[56266.]—**Rolled Iron Joist.**—The dimensions given will safely carry nine tons.—Arefes.

[56266.]—**Rolled Iron Joists.**—Will have flanges 4½in. by about ½in. thick, and web about ⅜in. thick. The sectional area of each flange, including due proportion of web, may be taken as 5 square inches, with a distance between centres of flanges of 9½in., and with a span of 15ft. and a strain of 5 tons per square inch on the iron, the distributed load is 10 tons.—J. S. C.

## UNANSWERED QUERIES.

*The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered are repeated four weeks afterwards. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.*

## QUERIES.

[56267.]—**Surfaces.**—Will some fellow workman, engaged in the machine-tool trade, tell me how to make surfaces look like, what for want of a more explanatory term, I must call a sort of fish-scale pattern of scraping? I have tried to imitate it by grinding the scraper various shapes, but without success. It looks to be as if the surface was all scraped over in one direction and then, what I must again call the fish scales scraped on with a peculiarly ground-up scraper across the direction of the first scrape by a turn of the wrist, maintaining a trellised pattern throughout. It does not look difficult; nevertheless I can't do it. I should like to be told where I fail, by someone who is used to such a job. I don't want a reply from a novice—too many of whom, it appears to me, answer various queries without sufficient practical knowledge. The scraping in question is only for finish, and is little benefit to a tool, but looks very showy. I have had large surfaces to go over where truth has been more the object than pattern, but find something fresh to be learned day by day, even after near a quarter of a century spent as a—Tool Maker.

[56268.]—**Shocking Coil.**—I have at length completed my coil, but find, when I connect three Leclanché cells, that I get shocks too strong to bear in one hand, whilst in the other scarcely anything can be felt? Would J. Kean, or some other electric reader, kindly tell me how I can remedy same? I had to make two joints in my secondary coil near the end, to which I cannot get shocks. Would this cause it?—C. J. R.

[56269.]—**Collimation.**—Will a correspondent kindly compute the following for collimation error in a transit? I have worked it myself, but am not sure about the result:—

δ Orionis Feb. 28.85 23.7° S.
Wire I. 5h.25.22
" II. 5h.25.36.8.
" III. 5h.25 50
" IV. 5h.26.03.S.
" V. 5h.26.18
March 8.85 51 Cephei 87.13.30 N.
Wire I. 6h.35.50
" II. 6h 40 37
Instrument reversed.
Wire II. 6h.51.16
" I. 6h.56.03

—Rosicrucian.

[56270.]—**Lunar Perturbations.**—Would "F.R.A.S.," or some other astronomer who possesses Proctor's "Moon," second edition, kindly explain to me one or two points connected with the paragraph on page 68, which states the ratio between the sun's maximum perturbing action on the moon, and his direct action on that body? Proctor says in the paragraph referred to (inter alia) "Now the line from the earth to the sun is about 91,500,000 miles long; while the line $M_1$ A is equal to the diameter of the earth's orbit, or to 238,800 miles." I suppose the words "earth's orbit," in the above quotations, are a mistake for "moon's orbit," but what I particularly wish to know is this:—The line $M_1$ A, according to Fig. 12 (referred to on p. 63 of the second edition) is equal to the diameter of the moon's orbit, so why is 238,800 miles, instead of the diameter of the moon's orbit, used in the paragraph referred to, in order to obtain the ratio between the sun's direct action, and his perturbing action on the moon? A few words as to this point will exceedingly oblige.—Resultant Force.

[56271.]—**Portable Engine.**—Will "Invicta" or others, kindly tell me the best way to make a boiler for a model portable engine, also the size and thickness of plates required for a cylinder 1¼in. bore, 3½in. stroke, and also if I can make it with a single flue instead of tubes?—A New Subscriber.

[56272.]—**Lifting Water.**—Will any of "ours" kindly say what power would be required to raise a volume of water to the height of 90ft. through 10in. pipes, also what size bucket would be required to raise 300 ton 24 per hours through same, at the rate of 12 strokes per min.?—Student.

[56273.]—**Secondary Battery.**—I am making a secondary battery as follows, viz., four lead plates, 10in. by 8in., suspended from pieces of wood across top of wood box. Can you tell me if it matters what number of plates and how to connect them together? I want the accumulator to drive a small motor to take into the country once a week. I have a three-cell Leclanché battery, large size. Can you tell me if this would b suitable, if I give it intervals of rest? I have looked through all my back numbers, but cannot find anything about these batteries.—J. J. Hammond.

[56274.]—**London Intermediate Science Examination.**—I should be much obliged if any correspondent could give me the names of a few books suitabl for the requirements of the above examination, in the elements of co-ordinate geometry, also elementar spherical geometry? Is there any textbook that woul cover the ground of the biology syllabus for 1885?—A London Undergraduate.

[56275.]—**Eyepiece.**—I have an astronomic o.g of 45in. focus, and 3in. in diameter. I wish to construc for it an eyepiece, giving a power of 200, and will than some friend to say what focus, size, and distance apar the two plano-convex lenses must be, so as to make suitable Huyghenian eyepiece, giving 200 diameters?—E. B. F.

[56276.]—**Egyptian Troop Boats.**—Will any o your readers give me information where I can get sketch and measurement of the boats used on the Nil for the troops?—if in *Engineer*, or other paper, wha number?—Porcelain.

[56277.]—**Skewers.**—How are the wooden skewer made with a tapering point—if by any special machin please describe?—Porcelain.

[56278.]—**Wood Filler.**—Wanted an effective woo filler to go on yellow pine before varnishing, one whic will not raise the grain as much as ordinary size.—Porcelain.

[56279.]—**Tennis Grounds.**—I shall be glad to kno whether hard-rolled tar paving has been found suitabl in hot summer weather?—R. F.

[56280.]—**Lever Watch.**—I have an English lever watch, and sometimes it will go well for months, and neither lose nor gain, and then it will take a fit and lose, say, for a fortnight, and after that it will keep good time. Can any brother reader tell me the cause, and if I can get it made to keep time?—J. A. C.

[56281.]—**To "F.R.A.S."**—Will "F.R.A.S.," with his usual courtesy, give the longitude of the earth's last perihelion passage, which would be about Dec. 31st., 16 hours N.A. time?—J. A.

[56282.]—**N. E. Locos.**—Have any of the performances of the new bogie engines, 664, 1492, &c., built last year, from Mr. McDonnell's design, been published? If we are to believe the drivers, these engines are a truly dismal failure; so if there is anything to be said on the other side, perhaps some correspondent will let us have it?—W. B. Thompson.

[56283.]—**Small Dynamo.**—I am about to construct a small dynamo machine. The pole pieces are 3in wide, and 3in. square, looking sideways, bored out to receive a 2¼in. armature, and the cores are 1in. round iron, 6in. long. I mean to have a Catella ring armature, recently described in these pages. Please tell me what size and what quantity of insulated wire ought to be wound on fields to get best results, also how many five-candle-power Swan lamps will it light? How can I fix the plates on armature?—Amateur.

[56284.]—**Dynamo.**—I wish to study construction of dynamos before making one—what books should I read? G. A. Walton.

[56285.]—**Drilling Square Hole.**—I have purchased instructions and sample. The sample shows a clean square hole, but the instructions are unintelligible. The only one which is clear to me, states that if I don't understand how to make the tool, I can buy it. Can any reader describe the tool so that I can work from the instructions?—Geo. A. Walton.

[56286.]—**Gas-Engines.**—To "R. A."—You mentioned in letter No. 54520, 12th Sept., 1884, that it was your intention, after the completion of your letters on the Gas-Engine, to describe a gas-engine for small powers. Would you kindly give promised description, as I should like to make one?—Pontiauak.

[56287.]—**Four-footed Bird.**—Some time since this was noticed in these pages. Can any reader give further information concerning it?—Paul.

[56288.]—**Crank Shaft.**—What diameter should a crank shaft (double ended) be for a cylinder 1in bore, 3in. stroke? 2. Will the crank or flywheel have to be balanced, and if so, how?—Osman.

[56289.]—**Exhaust Pipe.**—Could anyone give a remedy for the disagreeable noise of the exhaust steam in chimney of a portable engine, without removing the tube from the chimney, as it is a nuisance to neighbourhood?—Isaac T. Davis.

[56290.]—**Water Gauge.**—I am working a 9-horse portable engine. Would some of our readers inform me why the water in the gauge glass rises out of sight every night, after drawing fire, and cannot be seen down again till after two hours run with engine in the morning? All passages are clear; it has only been in use four days. Makers, Barrow and Stewart.—Isaac T. Davis.

[56291.]—**Wheatstone's Bridge.**—Will someone please tell me the battery power required (that is the number of Leclanchés I should want) to measure resistances from 5 to 1,000 ohms, using 5 ohms in each left-hand arm of the bridge up to 500 ohms; and then 10 ohms in each left-hand arm to measure from 500 to 1,000 ohms? I shall have to measure these resistances shortly, and want to use the least number of cells in each case to get the best results.—M.M.I.Sc.S.

[56292.]—**Watch Work.**—Will any reader kindly inform me where I am in error? I have small English turns with the two centres ready for use, but fail to see how to turn down new pivot, as the end of staff intended for pivot is already in a hole of one of the centres, and, of course, cannot be reached with graver or file.—Turns.

[56293.]—**Geometrical Conics.**—A tangent to an ellipse, whose foci are S H, meets two given conjugate diameters in T, *t*. T S, *t* H meet in P: show that the locus of P is a circle.—W. H. B.

[56294.]—**Chemical.**—Will some chemist kindly formulate for me the action that takes place when chlorine is passed into milk of lime for producing calcium chlorate, used in the manufacture of potassium chlorate? Is any calcium chloride or calcium hypochlorite formed?—Caloric Acid.

[56295.]—**Soldering Lamp.**—Can any of "ours" suggest anything in the way of a small handy apparatus for soldering overhead telephone wires (chiefly $^{3}_{20}$ phosphor-bronze). A very small iron is sufficient for the purpose; but an ordinary fire-pot and copper bit is much too inconvenient to use on housetops, &c. Something that can be readily lighted and extinguished, and capable of being used in very rough weather is what is required. Some combination of spirit lamp, with copper soldering bit all in one, seems the most feasible arrangement. Any information or practical suggestion will be welcomed by H. Jones.

[56296.]—**Sand Blast.**—I have a gas-engine, and should like to construct a sand-blast arrangement in connection with the same. Should I be allowed? and, if so, would some of your correspondents kindly inform me how to proceed?—An Old Subscriber.

[56297.]—**Musical Bells.**—I have several octaves of these, and lately I have found them to produce harsh sounds even when softly rung. The leather tongues seem soft enough, and the springs are good. Can any reader give me a hint how I might rectify the harshness?—Roscott.

[59298.]—**Records of the Past.**—In the course of my reading I have lately come across references to a book called "Records of the Past." The book, I believe, contains the results of some discoveries which have been made in the East, and bearing on Jewish history. As I am unable to get a copy, I should be glad if any reader of the English Mechanic would explain the nature of the discoveries, and when and by whom they were made?—Alpha.

[56299.]—**Gramme Dynamo.**—Having succeeded in making a Gramme dynamo capable of lighting eight 5 c.p. lamps, and owing that success in part to knowledge gleaned from the pages of the English Mechanic, I am desirous of making a larger and more useful machine of the same type, and would be greatly obliged if some fellow amateur could give me the leading dimensions of a dynamo capable of maintaining twenty 20 c.p. lamps. The armature being the principal part, I should like to know its external diameter and the diameter and length of the iron wire ring, the best number of sections and the gauge of the wire to be employed. If the Pacinotti ring can be recommended, where can the rings be obtained? Would it be advisable to wind the machine in shunt, as it will only be used for incandescent work; or, if wanted, for arc work? Spare series wound coils can be exchanged for the shunt ones; in any case the relative resistances, with regard to the armature, would be useful knowledge. From the general dimensions of the machine, I shall be able to deduce the size of the F.M.s and pole-pieces; but the fuller the information given, the greater will be the facility with which the machine can be made by others besides—D'Eloo.

[56300.]—**Violoncello.**—Could any of your readers furnish me with the following particulars in making this instrument?—1. What are the general thicknesses of the back and belly? 2. What is the thickness of the ribs? 3. How can an amateur bend them to shape? 4. What is the most suitable mould? 5. The length and general dimensions of the bass bar? 6. The cutting of the *f* holes. 7. The neck and its fitting. I have an idea that if the lids are made about double the thickness of a violin set, I will not be far wrong. Am I correct? There does not appear to be any authority on the subject, although I have most of the latest publications on the subject.—Eleph.

[56301.]—**Flower-Pots.**—I am told by a friend from America, that flower-pots are made there by machinery, by means of moulds, and that paraffin was used to oil the moulds and the balls of clay. I have made some moulds and attached them to my lathe, which made very nice pots, but not one in twenty would leave the moulds through sticking. Can any one help me?—S. Arlidge.

[56302.]—**Japan.**—Can any of "ours" kindly inform me of a good method to strip Japan from old machines? —and oblige—Melto.

[56303.]—**Blowpipe Lamp.**—Would some reader kindly describe a paraffin lamp for use with the blowpipe? The expense of getting in gas would be too great for anything I should have to do. I would prefer one that would not make too bad a smell.—$H_2$ S.

[56304.]—**Query Meaning.**—An advertisement says that material A is 100 per cent. cheaper than material B. Suppose material B is £100 per ton; then what is the price of A. per ton? You can say that A. is 150 per cent. dearer than B, which I understand, as B. being £100 per ton, that A. would be £250 per ton. You can also say that A. is 99·999 per cent. cheaper than B., but can the first quoted phrase be right? If so, it seems to follow that A. can be 150 per cent cheaper than B., and it could then follow that the vendor had to pay the purchaser.—Z. Y. X.

[56305.]—**Albo Carbon.**—Will anyone give me chemical formula of this? At what heat does it melt and give off gas? Is the gas given off inflammable in the absence of oxygen or common air?—Z. Y. X.

[56306.]—**Boring Mill.**—To "Invicta."—Many thanks to "Invicta." What I want at present is simply a sketch of your smaller machine to be driven by hand and bolted on to the front or flange of cylinder. Is boring bar a screw, or is the head keyed on to it? Also, how is feed applied to head with cutters on boring bar, as the head has to travel the whole length of cylinder? Do they generally put in three cutters on head and all three to cut at once?—No. 1 to take first (or roughing cut), and No. 3 the finishing cut.—Hombre.

[56307.]—**Cheap Condenser.**—To "Novice."—The condenser is chromatic, not achromatic. The distance between the bottom of my stage and the top of the mirror (when flat or parallel to the stage) is 1¼in. bare; so there is less room in mine than in yours. I should screw the carrier into the hole in the stage, and mount a hemispherical lens, ¼in. diameter, in the sliding tube. Notice that you must use a plane mirror; mine was only concave, so I stuck a piece of plane mirror on the back.—Edward M. Nelson.

[56308.]—**Secondary Battery.**—I am desirous of making a battery of this type, for experimental purposes with my small Gramme dynamo. The dynamo will light up 8 by 5 c.p. lamps, and I should like the battery to be of sufficient size to do the same for a few hours, as I cannot always obtain the power necessary for driving my dynamo at night, and would therefore be glad to have an occasional substitute for it. Could any fellow reader give me an idea as to how to set to work to accomplish this, either by detailing the construction of one cell and giving the number of cells necessary, or by referring me to a source whence I may obtain this information?—D'Eloo.

[56309.]—**Parallaxes of Stars, Binary Stars, Place of Spica A D. O, &c.**—Would "F.R.A.S.," or some other astronomer kindly give a complete list of all the parallaxes of stars which have been determined, and their actual distances in solar distances or light years, and the periods of all the binary stars which have been calculated, with their eccentricities and semi-axis-majors. I have lately seen in a book that Spica Virginis has been supposed to have been the star of the Magi? What was its exact place in Anno Domini 0, and is there any foundation for this belief? What are the stars in the heavens which have the greatest proper motions, and what are the greatest amounts of proper motion known—say the first ten? Has the companion predicted to Procyon, owing to its irregular motion, been discovered yet? Answer would oblige others besides.—M. Askwright.

[56310.]—**Coil.**—Would some of our obliging friends state whether a condenser can be attached to a shocking coil, and, if so, does it increase the strength of shock? 2nd, What is the melting heat of nickel?—Melto.

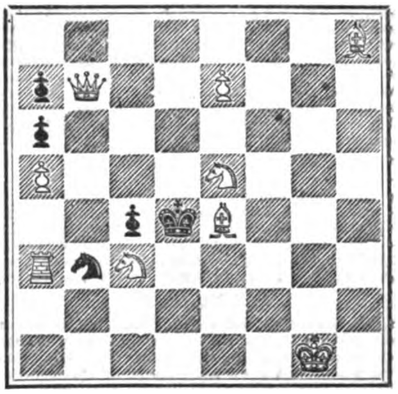
## CHESS.

All Communications for this department must be addressed to J. Pierce, Llandwrog, Carnavon.

### PROBLEM DCCCCXXXIII.—Tessie.

(Tourney Problem).

*Black.*



*White.* [9+5

**White to play and mate in two moves.**

### Solution to 931.

| *White.* | *Black.* |
|---|---|
| 1. R-K 2 | 1. P-K 3 (best) |
| 2. R-Q sq | 2. P takes R |
| 3. Kt-Q B 3 | 3. Anything |
| 4. Kt or P mates | |
| If 1<br>P takes P | 2. Kt takes P. &c. |

The author has overlooked the second solution beginning 1. R takes P.

The Solution Tourney begins with the above Problem 933. Solutions must be *received* before the publication of its solution.

Criticisms on the problems are invited.

### NOTICES TO CORRESPONDENTS

Correct solutions to 930 by C. Meiklejohn (second solution), R. C. J., Anon (both solutions), M. (ditto); to 931, by B. Fison (ditto), Rev. W. Anderson (Old Romney) and J. E. Piper—last two, second solutions.

H. Harborow.—Your solution to 931 is unintelligible.

Bethnal Green.—You have been unfortunate in both your attempts. In 930, Black on second move can take Kt with P; in 931, the K escapes on fourth move at R 4.

H. Jackson.—We have answered your inquiry by post.

"E.M." Tourney Game between J. Russell (White), and F. A. Vincent (Black)

(Evans declined).

1. P-K 4, P-K 4 / 2. Kt-K B 3, Kt-Q B 3 / 3. B-B 4, B-B 4 / 4. P-Q Kt 4, B-Kt 3 / 5. P-Q R 4, P-Q R 3 / 6. P-B 3, Kt B 3 / 7. P-Q 3, P-Q 3 / 8 Castles, B-K Kt 5 / 9. P-R 3, B-K 3 / 10. Q-Kt Q 2, P-K R 3 (*a*) / 11. B takes B(*b*), P takes B / 12. Kt-B 4 (*c*), B-R 2 / 13. R-R 2, Kt-K 2 / 14. Kt-R 4 (*d*), P-K Kt 4 / 15. Kt-B 3, Kt-Kt 3 (*e*) / 16. K-R 2, P-Kt 5 / 17. Kt-Kt sq (*f*) P-K R 4 / 18. B-Kt 5, P takes P / 19. Kt takes P at K R 3, P-Q 4 / 20. P takes P (*g*), Kt-Kt 5 (ch) / 21 K-R sq (*h*), Q takes P / 22. Q-K 2 (*i*), K-Q 2 / 23. P-B 3 (*k*), Q R-K B sq (*l*) / 24. R-K sq (*m*), R-B 4 / 25. Q-K 4, Kt-B 7 (ch) / 26. Kt takes Kt, R takes B / 27. K-Kt R 3, R-B 4 / 28. Q-R K 2, R-K sq / 29. P-Kt 5 (*o*), P takes P / 30. P takes P, B-B 4 / 31. Kt-R 5, Kt-B 5 / 32. Kt takes Kt, R takes Kt / 33. Q takes Q (ch) (*p*), P takes Q / 34. P-Q 4, P takes P / 35. Kt takes P (*q*), B-Kt 3 / 36. R takes R, R-R 5 (ch) / 37. K-Kt sq, P takes P (dis ch) / 38. R (K sq)—K 3 (*r*), R-K 5 (*s*) / 39. Resigns.

### Notes.

(*a*) Q-Q 2 seems better.

(*b*) Not commendable. Already Black has the better position.

(*c*) The Kt is no good here. Kt R 4, preferable.

(*d*) This is useless, and two moves thrown away. Why not Kt-R 2?

(*e*) Black, through the last few moves on both sides, is able to initiate a strong attack.

(*f*) Home, sweet home!

(*g*) Kt-Q 2 looks better than thus helping to develop Black's game.

(*h*) This shows that K should have gone to R sq on 16th move.

(*i*) P-B 3 driving the Kt away at once is better.

(*k*) Useless, as P dare not take Kt, on account of P takes P. There seems no objection to Q-K 4.

(*l*) Black keeps up the attack with vigour.

(*m*) Still Q-K 4? Note if P takes P, P takes P / R takes R, R takes P mate.

(*n*) To provide for Q takes Q, Black's attack is now effectually parried, and the prospects look drawish. White's next three moves are the result of a desire on his part to force the fighting, which had been better left to the adversary.

(*o*) To prevent P-Kt 4; but it enables the B to work its way round, and increase the attack.

(*p*) If Q-R 7 (ch), R-K 2 / Q takes R P, (B 5) B 2 and wins.

(*q*) Kt-Kt 3 would (as pointed out by Mr. Vincent) have at least secured a draw.

(*r*) If K-B sq, R-R 8 (ch) / K-K 2, R takes R (ch) / K takes R, K takes R / and Black's pawns must win.

(*s*) A beautiful move and decisive; altogether a surprise to White, who expected B takes R (ch) / R takes B, and the Kt returns in time to catch the pawns.

**Catapults**, 7d., 1s., 1s. 2d.; elastic 2d., 3d. foot; square 1d. to 4d. yard.—Moody Bell, Cheltenham.

**Elastic Stockings** for Varicose Veins.—W. Smith and Sons, 37, Breck-road, Liverpool. None made in London.

**Cat Gut**.—Gut Hooks and Eyes for lathes and machinery.—James Bellaers, Regent-street, Leicester.

**Bellaers' Gas Stoves**, 1s. 3d., 2s. 3d., 3s. 3s., for boiling. Breakfast Stoves, 8s., 11s., 14s. 6d. Send for lists.

**Edward W. Drury**, Hull, Glass Bottle and Cork Manufacturer, Importer of Chemicals, Caramel, Glucoses, Tinned Wire.

Edco six-cell **Battery**, twelve new porous pots, new zincs; will drive sewing machine, motor, or three 5 c.-p. lamps 120 hours without recharging for 8s. inclusive; last price, £4 10s. Cost £7 10s.—Address, C. R. Hear, 62, Coleman-street, E.C.

**Locomotive Photographs**.—N. L. Ry., G. N. Ry., &c., 8in. by 5in., 1s. Specimen carte and list, 5 stamps.—F. Moore, 1, Naas-road, Wood Green.

**Harmonium Reeds**, 2 sets, with pan, all best make, 36s.—J. H. G., 100, West-road, West Ham Park, E.

**Banjo**, with waterproof cover. 20s. Great bargain. Carriage paid.—J. Kinleyside, 61, George-street, Perth.

**Lathe**, 3½in. centre, with tools, chucks, leg vice: bargain.—Mechanic, 34, Crownfield-road, Leytonstone-road, Essex.

"**Thought-Reading**." Full explanation for 2s. 6d. —J. E. Parr, Ainsworth, Bolton, Lancashire.

**Diagrams**, large crayon, plain or coloured, for lectures on microscopy, &c.—J. E. Parr, Ainsworth, Bolton.

Twisting, Reeding, and Fluting **Lathe**. While inventing the spiral lathe my aim has been to make it in as few parts, to lessen the friction, and make it as cheap as possible, so that it may be within the reach of every woodturner. I have done small pillars of stone, coal, and clay. Will some one make an offer for it?—Scott.

**Koumiss**.—The secret of making this valuable wine price sixpence.—Robert Lawrence, 125, Thistle-street, Glasgow.

Model **Engine Castings**. Best and cheapest. See list (stamp) and compare.—Wood, Dalley-street, Broughton, Manchester.

Celebrated Kerry **Ferns**, 12 varieties, including rare filmy, 1s. 6d. free.—FitzPerr, Rathanny, Tralee, Kerry.

**Rose Engine Lathe**, with overhead, reciprocating, quantity of attachments; in excellent order; not rubbish, but a genuine bargain, £30 or offers. Also a Medallion Machine. May be seen by appointment.—Particulars from R. White, 50, Finsbury-square, London, E.C.

**Type-Writer** (Hall's), in perfect condition, £6, or offers.—R. White, 50, Finsbury-square, London, E.C.

**Tricycle Wheels**, Bicycle Wheels, and Fittings. Wonderfully cheap. Also for safety Bicycles.—W. Gwinnett and Co., Wolverhampton.

Upright Vertical **Engine**, cylinder 3in. long by 2⅜in. dia., flywheel 9½ dia.; would work a lathe; excellent order; cash, 25s.—R. H. Pease, 45, Chester-street, Saltney, Chester.

**Gas Bath Heater**, Phillips' patent, with towel warmer.—Baker, 9, Mincing-lane, London.

**Incandescent Carbon Lamps**, low resistance, 3s. each; Fairy Lamps, 3s. 6d.; Platinum Lamps, 1s. 3d., post free.—Todd, 14, Wentworth-road, Manor Park, Essex.

**Incandescent Lamp Holders**, new pattern, best in the trade, 12s. dozen; sample, post free, 1s. 3d.—Todd, as above.

**Formulas Worked Out** for winding Dynamos from 10 c.-p. to 500 c.-p., 8 stamps each.—H. Jones.

**Dynamo Castings**, 100 c.-p., cog armature, Gramme fields, 9s. a set. Motors with patent armature, 3s. a set. —H. Jones.

**Dynamos**, patent improvements, No. 2,122. 70 c.-p. machines, £5. 32 volts, ampères.—H. Jones.

**Dynamos**, best small machines in the trade, and cheapest double-covered Wires to 20 gauge, 1s. 8d. lb.—H. Jones.

**Dynamos** for Home Lighting.—5 lights, or arc of 600 c.-p. Price £6 10s., approval. Warranted.

**Dynamo Castings**, with laminated armatures, 8 c.-p., 5s.; 16, 5s. 6d.; 20, 6s. 6d.; 30, 7s. each.—H. Jones.

**Dynamo**, laminated armatures, no heating, ventilating; 70 c.-p., 16s. a set; finished, £5. Warranted.—H. Jones.

**Dynamo Machines Repaired**. Motors, with wire, 5s. 6d.—H. Jones, 48, High-street, Lambeth, S.E.

Model **Steam Engines** made or repaired. Separate parts fitted up, boilers made to order.—Lucas and Davies, 21, Charles-street, Hatton-garden, London.

Steel **Name Stamps**, 3d. per letter. Figures (set), 2s. 4d. Letters, 6s. 4d., per post.—E. F. Baldwin, Robinswood-hill, Gloucester.

Nickel-plated tubular pocket **Microscopes**, magnifying 5,000 times, post free, 1s.—Arnold, Spring-grove, Kingston, Surrey.

**Lathes**, Lathes. Cheapest and best. List, 2 stamps Nothing equal at price.—Robinson, Somerset-road, Sheffield.

The **Telegraph Tricycles**, T-framed, front steering, ball bearings, scientifically constructed. List free.—Norton, Crockherbtown, Cardiff.

Circular **Stocks and Dies** for cutting full threads at once running down. A great improvement on the old style. See testimonials. Price lists, one stamp.—Jerry and Son.

**Testimonial**:—"Gentlemen,—I am very satisfied with the screw-tackle. It is certainly a novelty. It is particularly well suited for amateur mechanics and small manufacturers." For full copy of this and other testimonials, send for lists.—Jerry and Son, North-street, Stafford.

**Hematite** for Jewellers.—Richard Baker and Co., 9, Mincing-lane, London.

**Brazilian Peebles** and Crystals.—Richard Baker and Co., 9, Mincing-lane, London.

**Rutil**.—Richard Baker and Co., 9, Mincing-lane, London.

**Lathe**, 3in. centre, bench, with machine cut backgear and Universal compound slide-rest, conical steel mandrels, steel collars, division plate, and index point. 2ft. 6in. planed gap bed with bridge, face plate, driver, and bell chuck, two T's, spanner, &c., new. Will take £5 15s., or with table, flywheel, and crank, £6 10s., a bargain.—Can be seen during the holidays at 102, Teviot-street, St. Leonard's road, Poplar, E.

Hardy British **Ferns** for Rockeries, Ferneries, Wardian Cases. Polypodium, Lemilacareum, Lastrea, Armila, Rigida, Colina, Oreopteris, Asplenium, Merenium, Ceterach, Crenatum, Viride, Oak, Beech, Calcareum, Athyrium, Parsley, Lobatum, &c. 15 free, 1s. 6d. 20 large Rockery Roots, 2s. Fifty, 4s. 1d. 100 8s., botanically named, carriage paid.—John Burns, Felside, Kendal.

**Universal Trade and Amateur Supply**.—Lecture requisites; light, heat, air, water, geology, engineering, chemistry, photography, &c. Wholesale and export.—Caplatzi.

**Coils**.—Experimental, Resistance, Medical, Dynamo, Bell, Telegraph, Galvanometer, and other purposes. Vacuum Tubes.

**Batteries**.—Thousands Lighting, Experimenting, Medical, Depositing. The Universal Four-cell Case, 18s. Convenient, durable, and economical.

**Dynamos**, Arc and Glow Lamps, Electric Lanterns, Castings. 10 kinds of Motors, Leads, Armatures, Dynamometers.

**Wires**.—Cheapest Stores. New and second-hand. Great reduction in price. Paraffin, Vulcanite, Reels, Brasswork, Cores, various.

**Machinery**.—Several good Lathes, Litho, Printing, Stamping Presses, Flatting Mills, Wheel-cutting Engines, Swiss Mandrels, Wire Covering Machines.

**Model Engines** to 2 H.P. Great number of 1, 2, 3in. stroke ones; good boilers, cylinders, gauges, wheels, cocks, pumps, boats.

**Dispensary Fittings**.—Drawers, Counter, Scales, Show Bottles, Jars, Instruments, Pill Machines, Splints, Trusses, Medicine Chests, &c.

**Telescopes**.—Fine 48in., 40s.; 54in., 60s.; 60in., 80s. Excellent two quarter Ross, 60s. Tripod Stands, 20, 30, 50s.

**O.G.'s** in Cells, 3, 3½, 3¾. Best make. Specula, Flats, Circles, Prisms, Micro. Powers, Eyepieces, cheap.

**Surveyor's Perambulator**, Theodolites, Compasses, Crossstaffs, Stands, Chains, Pentagraphs, Instruments, Levels, Miners' Dials, Quadrants, Sextants, 16 Vols. "Engineer."

**Type**, Stone, Litho, Printing, Rolling, Copying, Stamping Presses, Galleys, Wood Blocks, Accessories.

**Magic Lanterns**, Slides, Microscopes, Kaleidoscopes. Oil and Lime Burners. Retorts, Bags, Bottles, Condensers, Lamp Reflectors, Lantern Bodies.

**Photography**.—Triplet, Symmetrical, and cheap lenses. Best Stands, Printing Necessaries, double backs, 2 tons of Negatives.

**Slides**.—Superior, painted, comic and effects, Scientific, immense selection. Skilled exhibitors for town and the provinces very moderate.

**Presents**.—50 Microscopes, 100 Accessories, Objects, Cabinets, Powers, Condensers, Stands, Books, exceptionally low prices—2s.-£10.

**Chemistry**.—Fittings-up of complete Laboratories, Copper Troughs, Gasholders, Stills, Baths, Porcelain. Many Balances, Platinum, 2 thirds price.

**Hire**.—Occasional Lecturers and Bazaars will receive good terms, many facilities, with Apparatus of all kinds.—Caplatzi.

New Catalogue, 2d. **Caplatzi**, Science Depot, Hire and Exchange, Chenies-street, Tottenham-court-road, near British Museum.

Beautifully finished Quarter-Horse **Engine, Boiler**, and Donkey Pump for Sale. Wanted, Drilling Machine.—Skurray, Reading.

"**Gosse's British Sea Anemones and Corals**." Beautiful coloured plates, scarce, 15s.—Buffham, Connaught-road, Walthamstow.

"**Lyell's Geological Evidences of the** Antiquity of Man," 4th edition, 9s.—Buffham, Connaught road, Walthamstow.

For **Steam Pump and Light Feed Lubricators**—apply, Capps, Engineer, Hop Exchange, Southwark-street, London, S.E.

Two new Vertical **Engines**, 5-h.-p., compact and well-made, heavy flywheel.—Apply, Capps, Engineer.

Two H.-P. Vertical **Engine and Boiler**, by Tangye, equal to new, gold medal pattern.—Apply, Capps.

For "Metamorphic" **Plastic Steam Joint** Cement.—Apply, Capps, Engineer, Hop Exchange, Southwark-street, London, S.E.

The Amateur's **Gas Engine**. Simple and compact. Castings, 42s. Drawing, 5s. Litho., 3 stamps.—A. Dorrington, West Gorton, Manchester.

Half horse-power Horizontal **Engine Castings**, ports in cylinder, 12s. 6d. Drawing, 18 stamps. Litho., 2 stamps.—A. Dorrington, West Gorton, Manchester.

No. 2 **Drilling Machine**, self-acting feed motion. Castings, 7s. 6d. Forgings, 5s. Drawing, 18 stamps.—A. Dorrington, West Gorton, Manchester.

Model Compound Condensing Marine **Screw Engine**, perfect model. Castings, 18s. Litho., 4 stamps.—A. Dorrington, West Gorton, Manchester.

**Drawings** made of every description. List of Castings and Drawings, 1 stamp.—A. Dorrington, West Gorton, Manchester.

**Seed Protectors**—Moving Garden Cats. Great demand reduced the price, 21 stamps.—Bell, Metallurgist, Bexley Heath.

**The Perfect Pea Trainers** (Patented). Send for price list to Thomson's, Seed Merchants, 20, High-street, Birmingham.

**Hand Drilling Machine**, drills ¾ inch holes 6 inches from edge, 25s. Photo 3 stamps.—S. Beeching, Mareham-le-Fen, Boston.

Riveted Steel **Boiler**, 18 inches by 12, steam gauge, &c. Answer, stamp. 35s., together, 60s.—Below.

**Engine**, Horizontal, 1¼ inch bore, powerful, 28s.—Roberts, 2, City Garden-row, City-road, London.

**Type Writer**, Remington, capitals only.—Specimens and price from Ratcliff, 20, Cardoza-road, London, N.

**Astronomical Telescope**, 3-inch achromatic, Dollond eyepieces, diagonal, stand, &c., perfect condition, 55s.—Particulars, stamp.

Also 2¼-inch by Browning, astro., terrestrial, sun eyepieces, stand, 40s.—Atcombe, 7, Graham-street, St. Luke's.

**Advice** upon any Electric Bell difficulties by return of post. Terms, 1s.—Waggot, Electrician, Chester-le-street, Durham.

**Tricycle**, "Coventry Rotary," in good order, cheap, 5 guineas.—J. Brooke, West-street, Alford, Lincolnshire.

"**English Mechanic**," Vols. XXII., to XL., clean, complete, 40s.—W. Mayor, 62, St. Stephen-street, Salford.

50-inch Special Club **Bicycle**, almost equals new, cost £20. What cash offers?—56, Southampton-street, Reading.

Cotton-covered **Wire**, d.c., 10 to 18, at 1s. 6d.; 20, 22, 24, 26, at 1s. 9d., 2s., 2s. 3d., and 2s. 6d. lb. Bell Wire (cotton and rubber covered), 1d. per yard.—Darvill, 8, Brent View-road, The Hyde, London, N.W.

## Wanted

Old Microscopes, by Adams, Amici, Baker, Dollond B Martin, Pritchard (Goring's "Engiscope"), Varley, and other old makers.—J. Mayall, Junior, 224, Regent-street, London, W.

Birmingham Goods.—Jewellery, Watches, Clocks, Hardware, Harmoniums, Furniture. Agents wanted. Wholesale catalogues, 600 Illustrations free.—Henry May, Merchant, Birmingham.

Agents Wanted on commission to sell a new Invention to users of steam power.—Apply Salford Injector and Ejector Co., Salford.

Agents Wanted.—Morgan's celebrated Improved Scale Preventing Compound. Nothing better or cheaper.—W. H. Morgan, Engineer, Gloucester.

Deer Horns Wanted.—M. Day, Hook and Handle Manufacturer, 56, Driffield-road, Old Ford, London.

Patents, Designs and Trade Marks wanted to be made known.—For particulars of lowest charges, apply to G. L., Technical Bureau, 46, Queen Victoria-street, E.C.

Engine, about 1¼-inch bore, good condition.—Price and particulars, Atcombe, 7, Graham-street, St. Luke's.

Important.—Agents required for celebrated thirty-guinea Iron Grand Piano.—Apply, immediately, 5, Humber Chambers, Hull

Wanted, Launch Hull, or boat suitable for converting into same, 20 to 25 feet.—Chaplin, 61, Spring gardens, Doncaster.

## Addresses.

Will "Invicta" kindly communicate with me, *re* Oil-Gas?—W. Friday, 17, King-street, Canterbury.

Address wanted.—"Country Parson," oblige.—Address. C. G. F., 100, Elmore-street, London, N.

## Situations.

Mathematical Instrument Maker (Theodolite speciality) requires Situation.—Address, Friedrich Marquart, 17, Benedict-road, Brixton, S.W.

---

**WORKING MODEL STEAM ENGINES.**—The largest and most complete stock in the world. Castings of Foot Lathes, Working Model Steam Engines, &c. Sets of Castings for making Engines of all sizes; Working Drawings for same.

**BATEMAN'S MECHANICAL HANDY BOOK**, incorporating a Descriptive Priced Catalogue elaborately illustrated (100 engravings), post free, six stamps.

**MODEL SHIPS and SHIPS' FITTINGS.**—Bateman's new SHIPPING HANDY BOOK now ready. The most complete catalogue published, profusely illustrated, post free, 4 stamps. Mechanical Amusement, Popular Science—all feeling an interest in should send for Bateman's interesting Prospectus, post free.

J. BATEMAN, 131, High Holborn; and Branches, London.

**THIS ELECTRIC BELL**

**AND SPRING PUSH FOR 1s.**

1/-

1/-

On receipt of 16 stamps we will forward, carriage free, ALL THE PARTS for constructing the above invaluable appliance, together with instructions and diagrams. The whole arrangement being so simple that a child can put it together without any previous knowledge of electricity.

The apparatus comprises rich-toned nickel-plated Bell, powerful Electro-magnet, Insulated Copper Wires, Base Board, Brass Spring, Vibrating Armature, Contact Breaker, with platinum connections, improved Spring Push, and sundry fittings, altogether 20 distinct parts. Never before has such a marvel been produced for a shilling, and we rely entirely upon the ENORMOUS NUMBER we shall sell to repay us.

**SHOCKING COILS.**

1/-

1/-

On receipt of 16 stamps we will forward, carriage paid, ALL THE PARTS for constructing this marvellous machine. To put it together combines instruction with amusement, and it is so simple that a child can do it. When completed it is equal in power to those sold by opticians at a guinea, and for all medical purposes (curing nervous or muscular disorders, &c.) it is equal to the most expensive machines.—Vide Medical Testimonials.

Those wishing to purchase the Medical Coil in working order can have same sent, carriage free, for 2s. 9d. This is a beautifully finished article, with plated fittings and polished mahogany base.

THE TRADE SUPPLIED. WRITE FOR LIST.

Address, MANAGER (M. Department),

**ECONOMICAL ELECTRIC SUPPLY CO.,**

CHURSON WORKS, WOOD GREEN, LONDON, N.

AND WORLD OF SCIENCE AND ART.
*FRIDAY, APRIL* 10, 1885.

## MODERN RAILWAY FACILITIES.

ALTHOUGH, according to the adage, "familiarity breeds contempt," it is certain that railways and locomotives have an extraordinary hold on the mind, not only of those who have a mechanical turn, but also of many who know little of the inner mysteries and study only the time-tables. It is not by any means news to those acquainted with the history of the subject to be told that they travel no faster nowadays than they did thirty years ago—nay, not even so fast as they could have travelled by one train on the Great Western; but only those who study the subject are aware that no such services as we now have on our main lines were available even twenty years ago. There is at present no desire to exceed a running average speed of, say, 50 miles per hour, for high speeds mean a great increase in working cost; but there is, at least where competing lines touch the same places, much endeavour to increase the comfort of passengers, to study punctuality, and to run longer trains. The high speeds of thirty years ago were made with trains of two or at most three coaches, but they did not pay, and so far as the travelling was concerned the passengers had much to complain of. Nowadays railway travelling in Pullman cars and saloon carriages is almost a luxury—at least, it can be accomplished with ease and comfort, and the passenger who leaves London at 10 a.m. can be in Glasgow or Edinburgh by seven in the evening without feeling any inordinate amount of fatigue. If he likes he can dine without leaving the train, or, if he prefers it, he can travel at night and go comfortably to bed, to find himself at his destination when he awakes in the morning. These modern facilities are not so much appreciated in this country as they are on the Continent and in America, for the longest journey here is a mere trip compared to the runs which are now made with regularity and punctuality in Europe and America. In a paper recently read by Mr. Barnet Le Van before the Franklin Institute, the claim is made that the most luxurious travelling is to be found on the Pennsylvania Railroad, which for long-distance runs stands first in the whole world. The New York and Chicago "limited" accomplishes a distance of 912·2 miles in twenty-six and a half hours, including the ferry at New York and eight stops, which consume sixty-six minutes—thus giving an average running time of 36·18 miles per hour; but that does not satisfy Mr. Le Van, for he holds that if the law would only step in and make such regulations as prevail in this country, America could far surpass England, for here the law gives the companies complete control over their roads, while in America not only are sharper curves allowed, but the companies are compelled to run their trains subject to all sorts of rights of trespass on the track. As to the question of safety, Mr. Le Van contends that the safest line is the one which is best managed, and to run the most and fastest trains it is obliged to be the best managed. According to Mr. Le Van, railway speed in America, both for short and long distance runs, is second to none obtained elsewhere. For evidence in support of this statement, he points to the run between Baltimore and Washington on the Baltimore and Ohio road, where a distance of 40 miles is run in 45 minutes, or a speed of 53⅓ miles; to the run between Germantown Junction and Jersey City on the Pennsylvania line, which is 84·3 miles, and is accomplished in 1 hour and 44 minutes, or, roughly, a speed of 50 miles an hour; and to the run from Altoona to Harrisburg on the same line which is done in 3 hours 20 minutes, a speed of 39½ miles for 132 miles. It will be seen that there is nothing in these examples to compare with the Great Western run to Swindon, 77 miles at the rate of nearly 54 miles per hour, or with the Great Northern, Grantham to King's Cross, 105½ miles at the rate of 51 miles per hour. In long-distance runs the Pennsylvania Railroad stands "first in the world" because no other line has control of such distances; but it cannot be doubted that if either the Great Western or the Great Northern experienced any necessity for accomplishing a rate of 51 miles over a distance of 1,000 they would do it, for there is nothing about American locomotives or rolling stock which renders them superior to what can be found on our first-class railways. Pullman cars do not find much patronage in this country, except from a certain class who frequent race meetings and the like; as a matter of fact, they share only in the patronage obtained by modern saloon coaches and ordinary first-class carriages, which, to the ordinary Britisher, are the essence of luxury, if not of comfort, on even long-distance journeys—such long distances as we have here, that is. The running on the Pennsylvania road, however, is probably quite as much as can be expected, for within certain limits railway speed is a matter which is determined by the fares passengers are prepared to pay. As it is, on the portion between New York and Philadelphia there are bits which are run at the rate of 70 miles an hour, and the whole distance of just upon 90 miles might be done quicker than it is if it were not for the fact that, with the exception of a few straight runs, the line is really a series of curves and re-curves, some of which are of rather small radius. With all these drawbacks—90 curves in 90 miles, the total curvature of which would complete 10 circles—the Pennsylvania line runs one train each way daily at the rate of nearly 50 miles an hour between Philadelphia and New York, and it would probably run more if there were passengers to foot the bill. That is the gist of the whole matter. Heavy trains and stiff gradients limit the speed; but railway companies both here and in America are prepared to run at higher velocities if the public demand them, and are prepared to pay the price. But as it is, to make 50 miles over a long distance parts must be run at 70 miles or more, and there is not much likelihood of any regular trains being run here or in the United States at much quicker rates than can be found nowadays. As a matter of fact, railway companies have means of knowing exactly what they can do at given prices; and though the Great Western line remains the same as it always has been, we hear nothing of those fast expresses which, when Gooch's 8ft. engines were first put on the line, ran from Paddington to Didcot, a distance of 53 miles, in from 48 to 50 minutes. Running speed is still as high as ever it was, except, perhaps, in connection with the train just mentioned, which in 1847 rarely had more than three coaches; for time is now lost at stations owing to the increased number of passengers (and their luggage), and the average is reduced by the "waits." It has been calculated that each mile of speed above 40 miles an hour represents now twice as much performance as it did thirty years ago; but what we have to consider in "modern railway facilities" is the fact that where thirty years back there was one specially fast train, there are now a dozen all running almost as fast as that one engine and perhaps three coaches which constituted the "express" of a generation ago. The high speed attained on the 40 miles of the Baltimore and Ohio road between Baltimore and Washington seems to have led the pen of Mr. Barnet Le Van slightly astray, for he speaks of that road as having marked "many an epoch in railroad history," and as the "first passenger railroad in the world." But the facts are that the Baltimore and Ohio line was commenced on July 4, 1828, and 15 miles were opened as the first passenger line in America in 1830, the cars being drawn by horses. The first railway in the United States was one of two miles, which in 1826 ran from Milton to Quincy, a distance of two miles, and was worked by horses. The Liverpool and Manchester and the Baltimore and Ohio lines were in reality contemporary, but it was not until the utility of the locomotive had been demonstrated on the former that it found its way on to the latter, the first locomotive for which was built by Davis of York, Pennsylvania, with upright boiler and cylinders. The Baltimore and Ohio line can no more claim to be the first passenger railway than can the Liverpool and Manchester, but it is certain that Philadelphia can claim to have in Oliver Evans one of the pioneers of railways—a man who foresaw what they would arrive at within the next generation. Oliver Evans was the first in America to start a steam carriage, and it was he who stated that it would travel at such speed that it would be possible for the traveller to set out from Washington in the morning, breakfast in Baltimore, dine at Philadelphia, and sup in New York on the same day. Stephenson said that the time would come when it would be cheaper for the working man to travel by steam than to walk, and all the world knows now that Stephenson's dictum did scant justice to the railway, for the cost of boot leather, not to speak of the expense of lodgings and the loss of time, would make a considerable item when compared with the fare charged nowadays. A workman can at the present time transport himself wherever he is wanted at a comparatively small outlay, while those who can afford luxuries can travel with ease and comfort over distances which were veritable journeys to their ancestors. Reflecting on things as they are compared to what they were half a century ago, and remembering the pithy words of Edward Pease, "Let the country but make the railroads and the railroads will make the country," it must be acknowledged that we owe much of our prosperity, and nearly all of our contentment and comfort, to the "modern railway facilities."

## REVIEWS.

*Elementary Textbook of Zoology*. By Dr. C. CLAUS. Translated and edited by ADAM SEDGWICK, M.A., with the assistance of F. G. HEATHCOATE, B.A. London: W. Swan Sonnenschein and Co.

WE noticed the first part of this work on p. 353 of the last volume, and mentioned then that, edited by Mr. Sedgwick, Claus's "Elementary Zoology" easily takes first place amongst books of the kind. The special part, "Mollusca to Man," is paged as a separate volume, but the engravings are numbered consecutively with those in the first part, an arrangement which has an advantage when the student remembers a subject by the number of the illustration. The view taken by Dr. Claus of the position of man in the animal kingdom may be gathered from the following sentences:—"All these peculiarities, which are of the greatest importance for the intellectual development of man, cannot be regarded as fundamental distinctions, but must rather be ascribed to gradual deviations, since there are still greater differences between the highest and lowest apes. Efforts have been vainly made to show that certain parts, which are always present in apes and other mammals, are absent in man; and the attempts to prove the converse of this—viz., that there are parts of fundamental value in the human organism which are found in no other mammal—have as completely failed." A student of this work who carefully follows it from beginning to end—taking nothing upon trust that he can possibly verify for himself—will probably arrive at the same conclusion as the author and editor, that the high intellectual development and the possession of articulate speech, which render man capable of reaching perfection, form a great gap between him and the highest beast, but still leave him separated from the higher animals only in the degree of development to which his mind has attained. As an elementary textbook of zoology the work covers the whole field, and, while necessarily dealing with many points in a brief manner, still affords the student all the information he needs before tackling the more elaborate monographs on branches of the subject. The notes referring to the authorities will be found of much assistance.

*Harbours and Docks.* By Leveson Francis Vernon-Harcourt, M.A. Oxford: Clarendon Press.

This work, which appears in two volumes (text and plates), is issued in the Clarendon Press Series, and should be of considerable value to the rising generation of civil engineers, for besides embodying in its pages the results of personal observation, experience, and practice, Mr. Harcourt has freely sought the co-operation of his professional brethren, and consequently we have details and plans of harbours and docks in all parts of the world. The plans on the different plates are all drawn to the same scale, so that they are comparable at a glance. The preliminary chapters deal with the varieties of harbours, influence and prevalence of wind, the generation of waves and their force; the tides, currents, and changes produced in coasts; forms of harbours, and so on. The author then proceeds by classifying harbours, e.g., those with jetties, with rubble mound breakwaters, with concrete block mound breakwaters, &c. No harbour at which any engineering work of importance has been carried out seems to have altogether escaped, and of many he gives a full description and plan. Docks and quays are treated in a similar manner, and to a certain extent lighthouses also; in fact, the work describes the physical features, history, construction, equipment, and maintenance of harbours and docks, with statistics as to their commercial development. It will be of great utility to many besides civil engineers.

*Chess Eccentricities.* By Major George Hope Verney. London: Longmans.

Major Verney's little work on "Four-Handed Chess," published in 1881, attracted so much attention that he has given us a more extended account of other varieties of the game of chess, nearly all of which he has tried and found interesting, while affording unlimited scope for the most scientific play. The work is appropriately named "Chess Eccentricities," for besides a description of the four-handed game, which is becoming widely known, Major Verney explains the mysteries of three-handed chess on a board of 136 squares as devised by Marinelli, and his own plan of three-handed round chess on 96 squares. Chess for six players on 192 squares, and the game for eight players on 448 squares also have some pages devoted to them. For those who wish to try their hands at a game differing materially from the ordinary two-handed chess, Major Verney recommends one of the "eccentricities" on a round board; and those who wish to test their skill, science, and forethought are advised to try the three-handed game of Marinelli or that of Tesche. The volume is full of matter which will interest students of chess who take a wider view of the game than is possible with the ordinary board.

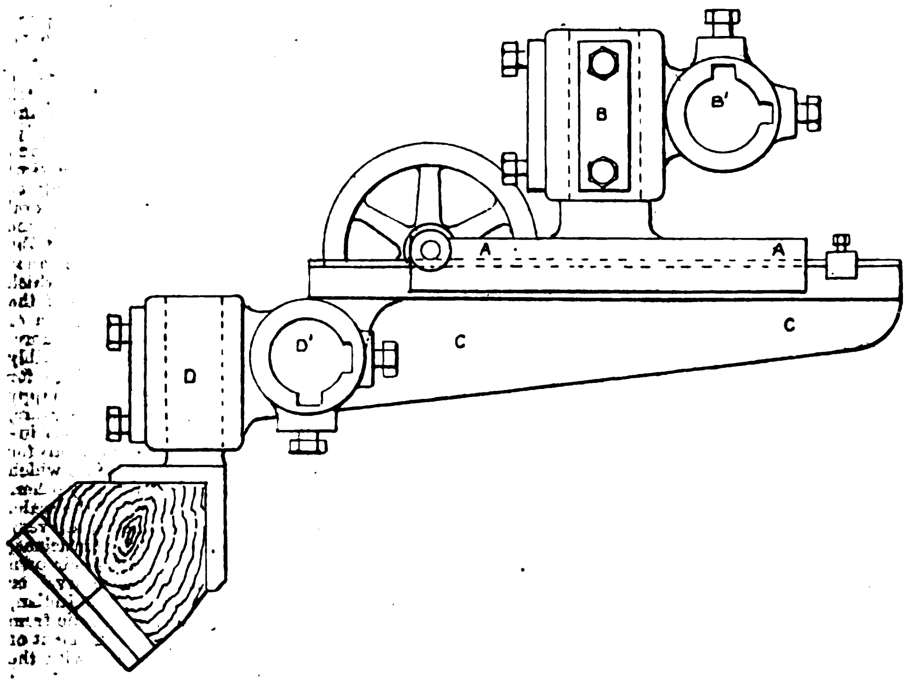
*Lessons in Elementary Practical Physics.* By Balfour Stewart, M.A., and W. W. Haldane Gee. London: Macmillan and Co.

This work is in reality an elaboration of the manuscript notes which Professor Stewart and the assistant lecturer and demonstrator in physics at Owens College have used in the laboratory of that institution. Nowadays manuscript notes have to be very voluminous to answer all purposes, and it is inconvenient to be continually referring to books which are of necessity located in the library; hence the authors determined to collect the notes and gather them into a volume for use in the laboratory; but they soon discovered that the matter grew in their hands, and accordingly determined to divide it into three volumes, the first of which, that on the general physical processes, is now published. It will be followed by others dealing with "Electricity and Magnetism," and "Heat, Light, and Sound." The plan adopted is to divide the matter into a series of lessons, each one descriptive of something to be done by a definite method with definite apparatus; hence there is very little of theory in the volume. Works of this kind are of much value, not only in the laboratory, but to those who have no chance of appreciating the advantages of a well-appointed "workshop."

We have also received *An Elementary Treatise on Dynamics*, by Benjamin Williamson, M.A., and Francis A. Tarleton (London: Longmans), which will be useful to those who desire an introduction to the higher works, for the authors start from the most elementary conceptions, and demand from the student only an acquaintance with the notation of the calculus.——*Physical Arithmetic*, by A. Macfarlane, M.A., D.Sc. (London: Macmillan), is a treatise on arithmetic chiefly as applied in physical science, and supplies a want which has long been recognised by examiners and teachers. The author adopts what he terms the equivalence method, in which each quantity is analysed into unit, numerical value, and, when necessary, descriptive phrase. The rate, or law, or convention, according to which one quantity depends on one or more other quantities, is expressed by an equivalence, which is either of dependence or substitution, and the equivalences are combined according to a form which is a development of the chain rule. The work will be found useful by all students of physics.——*Technological Dictionary of the Physical, Mechanical, and Chemical Sciences* (English-German), by F. J. Wershoven, D.Sc. (London: Symons and Co.), is the first part of a dictionary for science students, giving technical words in English, French, German, Italian, and Spanish.——The *Electricians' Directory* (London: G. Tucker) contains, besides a list of those commercially and professionally engaged in connection with electricity, a variety of useful information, and a "carefully compiled biographical section, giving interesting particulars concerning all the leading scientific men of the world"—a sentence which is misleading, for the biographical notes refer only to those who are connected in some way with electricity, either scientifically or commercially.——*Photo-Micrography*, by A. Cowley-Malley (London: H. K. Lewis), is the second edition of a work which is looked upon as the authority in the subject of which it treats. It is freely illustrated, and is adorned with some photo-micrographs.——*Standard Practical Plumbing*, by P. J. Davies (London: E. and F. N. Spon), is the first volume of a standard textbook on plumbing, the character of which can be gathered from the articles published in these columns. The matter has been rearranged, or rewritten, by the author, and the work is, in fact, the only treatise on practical plumbing which can be recommended to the diligent study of the apprentice.——*Scientific Theology*, by Thomas Walter Barber (London: Elliot Stock), is a series of essays towards the development of religious truth on the basis of modern science. The author tells us that he offers his remarks "more in the way of suggestion than authoritative or dogmatic statement, being fully aware that they are in no sense final"; but as he appears to think that scientific men "have all along either denied or refused to recognise" the existence of a power which they would be compelled to acknowledge if they attempted to arrive at the cause of the natural forces, scientific men can afford to leave the author of this work to the enjoyment of his opinions.——*Pottery Painting*, by Fred Miller (London: Wyman and Sons), is a course of instruction in the various methods of painting on pottery and porcelain, which may be recommended to those who desire to practise the art either as a pastime or as a means of livelihood.——*Wood-carving*, edited by Fred Miller (London: Wyman and Sons), is a useful work, chiefly valuable for its illustrations and descriptions of old work, though the editor has selected a number of practical hints from several authors.——*Notley's Commercial and School Book-keeping*, by A. F. Notley (London: Bemrose and Sons), will be found useful by teachers in schools, and also by those who are endeavouring to learn at home. Mr. Notley calls his subject the "Science of book-keeping," and he has certainly produced a manual which may be commended to all who desire to understand the mysteries of the art.——*A Handbook of the Teeth of Gears*, by G. B. Grant (Boston, Mass.: 66, Beverley-street), is a small pamphlet on the teeth of wheels, which will help to facilitate the comprehension of the subject by the average workman. The author describes some new odontographs, which he believes to be superior to those heretofore in use.——*A Collection of Examples on Heat and Electricity*, by H. H. Turner, B.A. (London: Macmillan), will be useful to many. The examples have been selected from examination papers set in various college examinations and the mathematical tripos.——*Elementary Principles of Carpentry*, by Thomas Tredgold, C.E., revised and enlarged by E. Wyndham Tarn (London: Crosby Lockwood and Co.), is the sixth edition of the standard authority in the English language. The publishers have done justice to the work by producing it in quarto size, with large type and excellent illustrations and plates. This sixth edition has been thoroughly revised by Mr. Tarn, who has rearranged a great portion of the contents and brought the whole up to date.

## MOULDING TOOTHED WHEELS.

An improved machine for moulding toothed wheels has been recently patented by Mr. J. Whittaker, of Oldham, who claims the combination of a slide having a universal joint with a mould carrier having similar play. The invention is applicable to wheel moulding machines of various constructions, the object of the invention being to adapt such machines to the special purpose of moulding helical or double helical toothed wheels, wherein the teeth are parallel to each other, but are at an angle to the axis of the wheel, or what are known as skew bevel wheels. In moulding wheels by machinery, it is usually the practice to withdraw the pattern from the sand either vertically or horizontally, according to the construction of the machine, or the wheel to be made; but it is difficult or altogether impracticable to withdraw the pattern of teeth of the above-described class from the sand by the ordinary machine, and in order to facilitate the moulding of this class of wheels, the patentee attaches to the ordinary machine a slide so constructed and arranged that it can be adjusted at any angle, so as to work either horizontally, vertically, or diagonally as may be required for withdrawing the patterns of this class of teeth from the sand. The mould carrier is also attached to the slide by a universal joint, so that it can be set at any required angle with regard to the slide, and by these means helical or skewed toothed wheels can be moulded by means of the ordinary moulding machine. In the drawing, which is a side elevation, it will be seen that the slide A A is fitted with a universal joint B B$^1$, the former part B of which works on a vertical axis, and the latter B$^1$ on a horizontal one, so that it can be set to move diagonally to any angle required. The arm or mould carrier C C is also provided with a similar universal joint D D$^1$ for the same purpose, and it will be evident that by the combination of these two universal joints, not only can the slide be set to move to and fro diagonally at any angle required, but that also the mould carrier may be adjusted to any desired angle with regard to the slide, and hence the moulding of helical spur wheels and skewed bevel wheels will be greatly facilitated, as the mould or pattern can be caused to enter and leave the sand in any direction and at any angle.



# NOTES ON CASSEGRAINS.—III.

By DR. ROYSTON-PIGOTT, F.R.S.

### Construction.

IN my last article (March 27, p. 72) the word "focus" is omitted, and the sentence should read: "The small convex being 20·9in. outside or beyond the convex *focus*, a cone of light converging thither will almost exactly fill the convex with light coming from an 18in. mirror, with the condition that the convex is $3\frac{1}{16}$in. in diameter."

We have not done yet with magnifying power. It so happens that we can get two values for it which gives an interesting method of finding the value of ($x$), the actual distance between the big focus, F, and the little focus, $f$; for we have two equations—

$$M = \frac{F}{E} \cdot \frac{F+f}{f}, \text{ and}$$

$$M = \frac{F}{E} \cdot \frac{f}{x}, \text{ whence}$$

$$\frac{f}{x} = \frac{F+f}{f}, \text{ or}$$

$$x = \frac{f^2}{F+f} = \frac{f}{\frac{F}{f}+1}.$$

Now, $f$ and F being given, $x$ is known. Example.—In my Cassegrains—

$$M = 129 : f = 28\tfrac{1}{2}.$$

Then—

$$x = \frac{28\frac{1}{2}}{\frac{129}{28\frac{1}{2}}+1} = \frac{28\frac{1}{2}}{5{\cdot}53} = 6{\cdot}28 = \text{F}f.$$

It is clear, then, the focus of the convex must be placed about 6¼in. beyond the focus F, or the convex surface be placed 22¼in., nearly, behind the big mirror's focus F.

In designing the Cassegrain several points are indispensable.

1. The diameter of the convex should exactly equal the diameter of aperture in great mirror, and be about one-sixth of it.

In my Cassegrain I ordered convexes of 40, 28½, and 16in. These had all to be adjusted to different positions, in order to throw the final image 15in. behind the aperture in the parabolic mirror. The focus F of this latter was 129in. It may be interesting to note the effects and positions of these appliances as regards change of focus.

In focussing with the 40in. convex by calculation, the eyepiece has to be shifted about 14 times faster than the convex—i.e., if convex is focussed 1-14th in., the eyepiece must be shifted above 1in. further away. Some heavy calculations are requisite for determining the results embodied in the accompanying table. I now proceed to the interesting question—the effect of slight movements in focussing with the convex mirror upon the position of the eyepiece.

### The Change of Focus in Cassegrains.

The Cassegrain can, in my opinion, become highly popular, especially in instruments of large size. At the present moment I propose to refer to an untouched point, the change in the final focus arising from small movements of the convex mirror. I take a case. Let

A F be sidereal focus of concave, 129in.
sidereal focus of convex, 40in.
A $f^1$ distance of final focus from concave, 107in.
A B distance of convex surface to concave, 99⅞in.

I now propose to move the convex gradually nearer to the concave and calculate the effects; as B moves towards A, $f^1$ moves a small space to to the left, i.e., A $f^1$ increases.

$$\overline{f^1 \quad A \qquad\qquad\qquad B \quad F \quad f}$$

At 107in. for B$f^1$ the ratio of the variation of the position of $f^1$ the final focus for a given small variation in the position of the convex $\frac{du}{dv}$ is 1 to 13½. When B$f^1$ reaches the value 120, the ratio becomes 1 to 16. In other words, the position of the concave is, so to speak, 16 times more sensitive than the eye focus. At present this state of things requires the small convex to be moved in change of focus by means of a distant screwed rod, or cord, as in the Melbourne monster Cassegrain; but it may fairly be expected that the foci may in time be brought to such a position as may permit focussing by the eyepiece. I have indications of this desirable result already. In the achromatic telescope it is well known that any instrument whose focus is not sensitive to the 1-50th of an inch change in the position of the eyepiece is of no

TABULAR RESULTS FROM CHANGING POSITION OF A CONVEX OF 28½ FOCUS, COMBINED WITH A CONCAVE OF 129IN. FOCUS.

| Dist. of convex from $f^1$, the eye focus. | Dist. of convex from concave focus. | Radius of convex. | Increase of B$f^1$ |
|---|---|---|---|
| B$f^1$. | B F | — | |
| 116·545in. | 22·9 | 28·5 | $\Delta_1 = 2{\cdot}637$ |
| 119·182in. | 23·0 | 28·5 | $\Delta_1 = 2{\cdot}734$ |
| 121·916in. | 23·1 | 28·5 | $\Delta_1 = 2{\cdot}839$ |
| 124·775in. | 23·2 | 28·5 | $\Delta_1 = 2{\cdot}947$ |
| 127·702in. | 23·3 | 28.5 | $\Delta_1 = 3{\cdot}063$ |
| 130·765in. | 23·4 | 28·5 | |

TABULAR VIEW OF THE FOCAL CHANGES FOR VARIATIONS IN THE POSITION OF THE CONVEX MIRROR.

| B F. | Inches B$f$. | Concave to final focus A$f$. | Convex to Concave Focus F. | Focus of Convex. | Dist. between mirrors A B | Ratio of variations of A$f$ and A B. | REMARKS. |
|---|---|---|---|---|---|---|---|
| 29·12 | 107 | 7½ | 29·12 | 40 | 99⅞ | Times<br>13½ | The eye focus $f^1$ is displaced 13½ times as much as the convex for this value of A B, the distance between mirrors. |
| 29·19 | 108 | 9·2 | 29·19 | 40 | 99·8 | 13·7 | The magnifying power increases in the ratio of B$f$ to B F, and if an eyepiece give power 107 for the first position, the power will be increased to 120 at the last. |
| 29·26 | 109 | 9½ | 29·26 | 40 | 99·75 | 14 | |
| 29½ | 110 | 10½ | 29½ | 40 | 99·66 | 14·1 | |
| 29·40 | 111 | 11·4 | 29·4 | 40 | 99·6 | 14·2 | The ratio of variation is as the square of B$f$ to the square of B F, Example $(111)^2 : (29{\cdot}40)^2 :: 121 : 182$. |
| 29·47 | 112 | 12·5 | 29·47 | 40 | 99·5 | 14·3 | Note.—A$f$ changes very nearly as fast as B$f$ diminishes, a remarkable property. If B$f$ gains an inch, so will A$f$. |
| 29·532 | 113 | 13·5 | 29·53 | 40 | 99·5 | 14·6 | |
| 29·610 | 114 | 14·6 | 29·61 | 40 | 99·4 | 14·8 | |
| 29·67 | 115 | 15·67 | 29·67 | 40 | 99·3 | 15·0 | Here a change in the final focus from the 2nd position amounts to 8in. for a movement of half an inch of the convex towards the concave. |
| 29·746 | 116 | 16·75 | 29·74 | 40 | 99·3 | 15·2 | |
| 29·80 | 117 | 17·8 | 29·80 | 40 | 99·1 | 15·3 | Remark.—The actual changes, not between convex and final focus, but between convex and focus of concave B F, are nearly 7-100ths for each increase of B$f$ an inch at a time. |
| 29·87 | 118 | 18·87 | 29·87 | 40 | 99·0 | 15·5 | |
| 29·94 | 119 | 19·94 | 29·937 | 40 | 99·0 | 15·8 | |
| 30 | 120 | 21 | 30 | 40 | 99·0 | 16 | Power increased from 107 to 120 by moving convex ⅛in. nearer concave mirror. |

extraordinary quality. Here a change of 3-100th of an inch for $Bf^1 = 112$ throws $f^1$ 1in. further from the convex. I have observed that the number of the diffraction rings presented by a star of the second magnitude can be decidedly changed with a very small focussing distance of the eyepiece. In an instrument of exquisite quality this valuable test of exalted beauty of definition may be applied—but at present, alas, for astronomical weather!*

These differences put into round numbers are 2·6, 2·7, 2·8, 2·9, 3·0, with a second difference of 0·1 nearly, showing that $Bf^1$ increases in arithmetical progression very nearly by the tenth of an inch for the same increase of distance between the convex and the focus of the big mirror (the concave). Whoever wishes to test the performance of his Cassegrain should never be satisfied till he has tried a considerable number of convexes against one standard parabolic concave, which can be essentially tested as a Newtonian. I possess six different convexes. The optician matches the various lenses of a microscopic objective with almost endless industry, now trying this pair, then that, till he obtains a minimum aberration for white, or for coloured light. In the Cassegrain we have only to deal with the aberration of homogeneous rays, and, therefore (neglecting eyepieces, which themselves are deeply afflicted with optical error), the question is one almost entirely of "marrying" the curves of the mirrors. A great variety of combinations practically are possible. To match a convex to a given concave is a difficult affair. If we plunge into the vivid phenomena given by solar discs in perfectly favourable air by splendid telescopes, and tabulate the niceties of change in the diffraction rings discoverable, both within and outside the best focal point (a course of philosophy during two favourable springs I do not again desire to undertake), doubtless we may arrive at strong conclusions for or against our favourite mirrors. For this purpose a small lens of the ⅓rd of an inch focal length gives splendid results placed to the north with the sun brilliantly shining upon it at a convenient distance—60yds. or more (Calver, I believe, prefers 150). Beyond 40yds. or 60yds. I have found the terrestrial radiation and warm-air currents excessively annoying except in the early part of spring, or even May. Daylight testing is then a pleasure —between 9 and 10 a.m.—after that hour the solar heat causes too much radiation and atmospheric undulation. I believe Schwabe chose the hour of 9 a.m. for solar spot observations, and, at that time, the air seems to be comparatively still and free from heat currents. Then is the time to test the focal changes wrought by slight focal displacements.

(*To be continued.*)

## THE MUSICAL SCALES OF VARIOUS NATIONS.

A LONG and elaborate paper on the Musical Scales of Various Nations, was read the other day, before the Society of Arts, by Mr. Alexander J. Ellis, F.R.S., but we can afford space only for the following extracts. The paper will be found in No. 1638 of the *Journal* of the Society, and is mainly composed of matter that is entirely new, which has been gathered together only by laborious research, and has been presented in a novel shape by Mr. Ellis, assisted by Mr. A. J. Hipkins.

In my "History of Musical Pitch," I defined "the pitch of a musical note to be the number of double or complete vibrations, backwards and forwards, made in each second by a particle of air while the note is heard;" and I gave a full account of the methods by which this is ascertained, and showed how, by means of a sufficiently long series of tuning-forks, first, their own pitch, and then the pitch of all other notes of sufficient duration which fall within their compass can be ascertained to one vibration in ten seconds. I chiefly used the forks of the late celebrated Scheibler for that paper. For the present investigation I have employed a much longer series of forks, with their pitch ascertained from those of Scheibler within that limit. Further, in Art. 3, I defined musical pitch to be "the pitch of any named musical note which determines the pitch of all the other notes in a particular system of tuning." By that system we are therefore able to tune all the notes on an instrument. These notes, when sounded in succession from the lowest to the highest—that is, from that which has the smallest to that which has the largest pitch number —forms the scale of the instrument, from which are selected the notes used for any piece of music forming the scale of that composition. The word scale properly means ladder, because the notes thus sounded give us the sensation of ascending by definite distances. An interval between any two notes is the sensation of the distance passed over in proceeding from the first note to the second. It is measured properly by the ratio of the smaller pitch number to the larger, or by the fraction formed by dividing the larger by the smaller. When these ratios are known for each successive pair of notes, the scale itself is known, for means then exist for tuning the whole scale when one of its notes is given. Clearly, if we assume, for the purposes of calculation, that the lowest note makes one vibration in a second (which could not be heard as a note), the ratios mentioned would give the corresponding numbers of vibrations for each note, and these all multiplied by the real audible number of vibrations in the lowest note, would give the absolute pitches of the actual notes heard. These ratios, therefore, are the important matters to ascertain, and they are said to give the relative pitch of each note in the scale. The absolute numbers, which is what engaged my attention last time, are now of little consequence. We do not want to know how to tune in any particular pitch, but how to tune at any pitch whatever. Hence it is the law which determines the relative pitch that we wish to find, or, in other words, the system of ratios or of their equivalents. Now these ratios convey no conception whatever to the musician, who, without considerable instruction, can attach no musical meaning to such ratios as 2 : 3, 3 : 4, 4 : 5, 5 : 6, 6 : 7, 7 : 8, 8 : 9, 9 : 10, and so on. Hence some other way of expressing them is necessary, especially for describing scales. It will not be, perhaps, too great an assumption to pre-suppose that every one present is acquainted with the pianoforte, and knows that it is divided into sets of tones called octaves, and that there are twelve digitals, or finger keys, to each octave, seven long and white, five short and black. But perhaps every one may not know (as he ought to know) that the object of the tuner is to make the interval (or sensation of distance or ascent) between any two notes answering to any two adjacent finger keys throughout the instrument precisely the same. The nearer he succeeds the better the tuner. The result is called equal temperament or tuning, and is the system at present used throughout Europe. For the purposes of measurement, I must assume that the tuner has succeeded, although I am bound to say that no tuner ever has as yet succeeded perfectly, on account of the great difficulty to be overcome. Then we say that the interval of an octave is divided into twelve equal intervals called semitones. Now I must go a step further. Suppose a piano made of such a gigantic size that we could interpose 99 smaller finger keys between any two at present existing, and that we could tune these at exactly equal intervals, called cents, so that 100 cents would form an equal semitone. It is as well to know at once that this is impossible. No ear has yet succeeded in hearing the interval of one cent between two notes played in succession. Even the interval of two cents requires very favourable circumstances to perceive, although five may be easily heard by good ears, and 10 to 20 ought to be at once recognised by all singers and tuners. When the two notes are played at the same time, these 2 cents make a distinct difference in consonances, and 5 cents are felt to be out of tune. The tuner has constantly to deal with intervals of from 2 to 22 cents. and he corrects his ear by playing the notes together. If, then, I say that a certain interval has 316 cents, I mean that it contains 3 semitones (counted by the keys on a piano) and 16 cents or a very little more. But how are we to determine the number of cents? By finding the interval ratio already mentioned, which is best ascertained from the absolute pitch numbers of each note, and may be approximately ascertained by taking the ratio of the sounding lengths of two pieces of the same musical string, when they are in unison with the two notes as determined on an accurate monochord. Having found these two numbers, the discovery of the number of cents is a mere matter of arithmetic. When the numbers of cents have been ascertained by the process, a scale, which I particularly leave unnamed, is written thus:—

| | | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| Vib. | 270 | | 308 | | 357 | | 411 | | 470 | | 540 |
| Cents | I. | 228 | II. | 256 | III. | 244 | IV. | 232 | V. | 240 | I'. |
| Sums | 0 | | 228 | | 484 | | 728 | | 960 | | 1,200 |

Here I., II., &c., are the notes of the particular scale, of which are here five, I'. being the octave of I. The numbers between these note-symbols show the number of cents in the interval from one to the other. The numbers under them show the number of cents in the interval from I. to the note in question. The number above is the absolute pitch number of the note as already defined, that is, the number of vibrations which it makes in a second, as found from observations. But this may be omitted when merely the relative pitch is wanted. Of course, practice preceded theory in music as in everything else. The sound of a fourth was perfectly well known to singers and lyrists, long before it was discovered that the whole length of a string and three-quarters of its length, when plucked, would give this very interval. But this once found, theory followed rapidly, and intervals were defined by lengths of string with great minuteness. It was the ratio of these lengths of string that was used to determine the intervals; and it is only of recent years that these lengths were found to be inversely proportional to the pitch numbers of the notes, and then these pitch numbers, which were applicable to all musical sounds, and not to those of strings only, became exclusively employed. The property just named, that the pitch numbers of notes are inversely proportional to the length of strings producing them is, unfortunately, quite true only for a heavy perfectly flexible and elastic mathematical line, limited by mathematical points, and any attempt to divide a real string of wire or catgut by bridges or frets fails for several reasons. In the case of frets, the pressure of the finger behind the fret increases the tension of the string and increases the pitch. This circumstance is of great importance in the Indian vina, which has very high frets, so that the pressure of the finger behind the fret can easily raise the pitch of the note by a semitone, that is 100 cents or more. Even in the modern guitar the intervals are sensibly sharpened. Hence the lengths of the strings for the principal intervals can only be termed a happy guess; and it remained for quite recent observers, such as Helmholtz, to establish, by ingenious instruments, that the actual ratios of vibrations for the consonant intervals was precisely those which are now well known, and could not be any other. Thus it was possible to have a theory of the scale. The theory implied exact measurements, all very well for instrument-makers, but not for musicians, who have only one standard to go by—their own ear, that is, their own appreciation of interval or relative pitch. Some musicians, like the Indian, repudiate all measurement and all arithmetic from the first, and leave everything to the judgment of the ear. In this country we are familiar with the pianoforte, harp, and violin, all of which are tuned exclusively by ear. For the harmonium, indeed, "beats" are available, but they are rarely used. On the contrary, organ-tuners are accustomed to a rough appreciation of the occurrence of beats, but few of them know the exact numbers, or understand how to employ them properly. Hence, as we may expect, tunings by ear, or the actual notes produced in the scale by a tuner, seldom or never give precisely those intervals which theory lays down. It seemed to me advisable, before trying uncivilised or semi-civilised nations, to see how well good English tuners could tune. Mr. Hipkins, who has the best possible means of knowing, says that it takes a quick man three years to learn to tune a piano properly. We may take it for granted, then, that most pianos are improperly tuned. Now, in order to find the scales which I have to communicate to-night, there were two courses only open—theory and practice. For Greece, Arabia and Persia, India and Japan, treatises exist, giving the scales more or less accurately; probably also for China, but they were not accessible to me. Where I could find these couched in intelligible language (very far from being generally the rule), I was glad to follow them, as they showed what those best able to judge considered to be aimed at in tuning. But the treatises that furnish accurate numbers are confined to Greece and Arabia, with Persia. Indian treatises rather ostentatiously eschew arithmetic, so that in reality their theory depends on oral tradition. In India, then, in China, in Java, and the various savage countries, there was nothing accessible but the instruments, and perhaps (as at the Aquarium in 1882, the International Exhibition of 1884, and the Japanese Village in 1885), native musical performers on a visit to England. Now, any musical instrument on which a native can play to the observer furnishes a set of notes actually produced, and these can have their pitch numbers determined with more or less certainty. In this way I was fortunate enough to get thirteen scales, five Indian, seven Chinese, and one Japanese, all recorded in numbers of vibrations, by the kind help of Mr. Hipkins. Instruments without a native performer seldom record themselves. Wind instruments, of course, require a native practised musician to blow, because the pitch can be greatly varied by the style of blowing. Stringed instruments without frets, or with movable frets, are also worthless without a native player. A stringed instrument with fixed frets (like the ordinary guitar), is, to a certain extent, available. If there are several strings, the law of tuning them is generally unknown. But if there are many frets on one string, enough to cover an octave (as on the guitar), then by measuring the vibrating lengths of the strings from the bridge to the edge of the fret next to the bridge, we can approximate to the relative pitch of the scale of notes which would be produced by sounding the string when properly stretched. The absolute pitch it is, of course, impossible to discover. That can only be obtained by help of a native performer, and would probably differ from one performer to another, for I have discovered nothing like a standard pitch anywhere. We have not yet arrived at fixing a standard pitch even for Europe. There are some instruments which play themselves. Anyone with proper tuning forks could count the pitch of the notes in a piano, dulcimer, harmonium, or organ, when they have once been tuned, provided they have not since had an opportunity to get out of tune, as such instruments so easily have—the harmonium least. The Chinese Shêng (and Japanese Shô) are reed instruments, not easy to sound certainly, but presumably rendering very nearly the sounds to which they have been tuned. The main instruments of uncivilised music, however, are flutes, bells, gongs, and harmonicons, consisting of bars of wood or metal. It is the last which have enabled us to obtain the pitch of the notes used even without the assistance of native players. Unfortunately, such harmonicons are apt to fall out of tune, and their intonation is injured by travelling, and (especially the wooden ones) by damp. Hence there is no practical way of arriving at the real pitch of a musical scale, when it cannot be heard as played by a native musician; and even in the latter case, we only obtain that particular musician's tuning of the scale, not the theory on which it was founded. To reverse the process, to go back from the best we can do with the instrument to an hypothesis concerning the relations intended, is very risky indeed. We certainly ought to do the best we can in this way, but we should never forget to give the observed data whence our hypothesis is derived. After all, we have only determined the notes used, not the scales employed for any piece of music. It would be impossible, from our knowing the twelve semitones to the octave used in Europe, to determine the double form of the major scale (without and with the grave second), and the triple form of the minor scale (without and with the major sixth and seventh), not to mention the so-called ecclesiastical modes. So in other countries. Here we are thrown entirely on theorists or information from natives, and where these fail us, we only know the notes employed, not the scales made by selecting some of them. In a few cases these are known, but in others we can only guess. There are, however, two distinct kinds of scales, considered as divisions of the octave used in playing airs. In the first, between a note and its octave, six notes are interposed, and the octave derives its name from the circumstance of being the eighth note, including both extremes. Occasionally two or more notes are left out, and occasionally one to three are inserted as alternative notes. But the main run of the scales consists of seven notes. The scales are called heptatonic, and are prevalent in Europe, Arabia, India, and other places. The next great division inserts only four notes between the first and what, from European habits, we still term the octave, which, however, is now the sixth note, both inclusive. These scales have in later times been often filled up by inserting two other notes; but these are clearly intrusive, and in the most typical case, Java, it has not been done. These scales are, therefore, termed pentatonic. They are found in the South Pacific, Java, China and Japan, and it is believed, from the nature of older Scotch, Irish, and Welsh melodies, were used by the Celts. Of the music of Egypt we know nothing; the instruments preserved, and their pictures, do not suffice to give a scale. We cannot tell what influence Egypt had on Greece. We do not know whence Greece derived her music, though Persia is a possible source. Different as all the Greek scales are in character, mainly shown by the final cadence, they all agreed in one point. They were purely melodic. They could not be sung in harmony, as in the modern chorale or part-song. To do this properly, it was necessary to alter all the intervals slighly. The principles on which this was possible was fully explained in my second edition of Helmholtz, App. XX. Sec. E, and cannot be intruded here. The final result, however, may be added. In this the C-mode was retained, and the others were fused into the A-mode, to which three forms were given. All these forms give beautiful consonances, which may be heard from almost any unaccompanied chorus, especially of tonic solfaists; but the consonances are greatly injured by the equal temperament which reduces the European scales to the following:—

---

* "Garrison Gunner," whose letters I have admired for years, does not seem to be aware that night reflectors can be made so as to resist atmospheric tarnish.

1. Major mode. C 200 D 200 E 100 F 200 G 200 A 200 B 100 c.
2. Minor mode, three forms:—
   - C 200 D 100 E fl. 200 F 200 G 100 A fl. 200 B fl. 200 c.
   - C 200 D 100 E fl. 200 F 200 G 200 A fl. 300 B 100 c.
   - C 200 D 100 E fl. 200 F 200 G 200 A 200 B 100 c.

This intonation, as I explained in my paper on the "History of Musical Pitch," is only about 40 years old in England. The scales played before that time at the Philharmonic concerts, and on all organs, though probably never heard from unaccompanied part singers, were in "mean tone intonation," or—

1. Major mode. C 193 D 193 E 119 F 194 G 193 A 193 B 117 C
2. Minor mode in three forms:—
   - C 193 D 117 E fl. 193 F 194 G 117 A fl. 193 B fl. 193 C
   - C 193 D 117 E fl. 193 F 194 G 117 A fl. 269 B fl. 117 C
   - C 193 D 117 E fl. 193 F 194 G 193 A 193 B 117 C

The object of all these changes was to reduce the number of necessary notes in the octave to 12. The last, or mean tone system, perfected by Salinas in 1577, prevailed over Europe for nearly 300 years. As long as only three sharps, F sh., C sh., and G sh., and to flats, B fl. and E fl., were required, it admirably answered its purpose of furnishing organs with endurable harmonies. But modern music requires perfectly free modulation, and the equal temperament was the only one which would furnish this within the limits of twelve notes to the octave. Hence, notwithstanding the harshness of its chords, arising from the undue sharpness of its major third, sixth, and seventh, it has prevailed universally, and many modern musicians are not even aware of its nature and defects, or that there ever was any other possible intonation. Mr. Ellis then described at length the musical scales found in Persia, Arabia, Syria, and the Scottish Highlands; those found in different parts of India, in Siam, Singapore, Burmah, West Africa, South Pacific, Java, China, and Japan. In concluding, he summarised the facts as follows:—First, the relation of the octave, naturally given by the voices of boys and men, is naturally recognised, although not always correctly tuned on the instruments examined. At this we must not be surprised, for it is often incorrectly tuned even on modern pianos. The next interval most generally appreciated is the fourth. All Greek music, and hence all modern European, as well as all old and mediæval music, is founded on this interval. The fifth seems to have been rather appreciated as the defect of the fourth from the octave, though modern tuners find the fifth much easier to appreciate than the fourth. The tone was appreciated only as the difference between two fourths and the octave, or between a fourth and a fifth. But, in very early times, in the tetrachord of Olympos, the just major third of 386 cents made its appearance, and with it the just diatonic semitone of 112 cents, as the difference between it and a fourth. Unless, indeed, as in Japan, the semitone was tuned by a kind of guess, and the major third obtained as the defect from a fourth —and this seems to be a very likely hypothesis. At any rate these intervals (assumed by Helmholtz as 15 : 16, or 112 cents, and 4 : 5, or 386 cents) were soon ousted by the strict system of fourths, on which the later Greek scale was formed. In Arabia and Persia, however, other distinctions came in. The old division of the fourth into C D E fl. E F was disliked, the E fl. of 294 cents from C was felt to be too flat. The Persians raised it to 303 cents, as nearly as possible to our equally tempered minor third, but retained the old E 408 cents. The division was then practically our equal one of 0 100 200 300 400 500 cents. But there was a lutist called Zalzal, who evidently disliked these 300 and 400 cents, and introduced the halfway-house or neutral 355 cents, where the ear is unable to determine whether the interval is major or minor. This practically employed the trumpet scale 8 : 9 : 10 : 11 : 12, for 10 : 11 is 167 cents, and 11 : 12 is 151 cents. An entirely new interval was thus introduced, and seems to have struck deep root, the interval of three-quarters of a tone. The mediæval Arabic system drove it out of classical musical scales, by continuing the number of fourths to 16, using, therefore, 17 notes, which gave very artificial scales, generally bordering on the old Greek, but often greatly diverging from them, occasionally employing even eight notes in a scale. The later Arabic forms, by dividing the octave into 24 equal quartertones, sufficiently reconciled Zalzal and the mediæval musicians. But the normal scale was Zalzal's of 0 200 350 500 700 850 1000 1200 cents, and this scale we imported into England, and still possess in the Highland bagpipe, which has not yet been harmonised. The attempt, however, to conform to the other Arabic scales led to sharpening or flattening any of these notes by a quarter of a tone, which was one of their degrees, thus producing a large number of varieties. Now, did India draw upon Arabia, or conversely? In India we have a remarkably complex system. First a scale very like our major, but with a sharpened sixth of 906 in place of 884 cents. There was consequently a separation of the scalar intervals into three kinds, major, minor, and half tones, and these were supposed to be divided into four, three and two equal parts respectively, which I have called degrees. Practically these, being produced by shifting frets, pressing on strings behind the fret, or deflecting them along the edge of the fret, were never precise, but were always about or slightly exceeding a quarter of a tone. Then came the habit of altering the intervals by a degree, which is extremely like the Arabic quartertone system; although it must have been generated independently, yet it certainly frequently produced in the different modes and modelets, those three-quarter tones which in Arabic music we owe to Zalzal. China and Japan introduced nothing new beyond the original limitation of the scale to five notes, which arose, in fact, from the divisions of tetrachords into two parts only, for example, a semitone and major third, like those of Olympos, whose very division we find in the popular music of Japan, or else into a tone and a minor third, the thirds arising in each case as defects of the first intervals from a fourth. Such tetrachords were then either conjunct or disjunct. But they were always capable of being completed into Greek scales, as has been actually done in Japan, and possibly in China. On the instruments as tuned or played by natives, China offers many examples of the three-quarter tone interval. But neither China nor Japan, any more than Europe, have reached the complete Quartertone system, which we find in Arabia, and practically in India. On the other hand, Japan at least, and China also, according to Amiot, have attained to a system of twelve, more or less exact, equal semitones. The double pentatonic system, as developed in Java, is, however, something new and entirely different from the Chinese and Japanese. The first system seems to be formed by taking the fourth flat enough to give, practically, a division of the octaves into five equal pentatones. Remarkably enough, the fourth note of the scale thus becomes very nearly indeed the natural harmonic seventh of the first note. But upon this system, if I am correct, both fourth and fifth are defective, the fourth being flat, and the fifth sharp. Whatever be the theory of the scale, this fact is certain, and it entirely destroys the assumption of the necessity of founding a scale upon the fourth or fifth. This is further confirmed by the second class of pentatonic scales in Java, for which I have not been able to find any satisfactory principle, although they adopt intervals of very nearly 100, 150, and 300 cents, that is nearly semitones, three-quarter tones, and minor thirds. This system has a fund of seven notes to the octave, and out of this fund it selects different sets of five to form a scale. Whereas, then, in the first system no interval between consecutive notes in so small as a tone, or so large as a minor third; in the second system, differences of 100, 150 (rarely or never 200), 300, 400, 450, and even 550 cents occur. The first set of scales are therefore remarkably uniform, the second as remarkably diverse. Another singular difference is that in the first system the fourth is flat, and the fifth sharp; but in the second the fourth is very sharp, almost a tritone, and the fifth is nearly a comma flat. In the first system, and on at least two scales of the second (Dangsoe and Bem), the harmonic seventh is developed. The final conclusion is that the musical scale is not one, not "natural," nor even founded necessarily on the laws of the constitution of musical sound, so beautifully worked out by Helmholtz, but very diverse, very artificial, and very capricious. At the same time the contributions I have been able to offer towards the study of this vast subject, are, notwithstanding the inordinate length of my paper, relatively very small and manifestly extremely imperfect in observations. They really require completion by the long and careful observation and study of many physicists who have some notion of music, rather than of musicians whose ears are trained to particular systems with but slight knowledge of physics.

## MALT AS FOOD.[*]

By J. Milner Fothergill, M.D.

MALT as food has a great future before it. In the process of malting (which is a rapid germination) a distinct change is brought about in the seed. By the action of the diastase the insoluble starch is converted into soluble dextrine, which goes sweet in the mouth, so near maltose is it. The malt-combings, which are too rich in albuminoids for the brewer's purposes, are useful when malt is looked at as a food. Malt contains dextrine (some diastase), soluble albuminoids and phosphates, and when ground is an admirable food, while it is not expensive. Its taste is pleasant. It can be made into a pudding with an egg and some milk, and as such is palatable. It can be made a constituent of a milk pudding with advantage. When the brewer mashes his malt with hot water the diastase remaining in the malt converts the dextrine into maltose, which the yeast (next added) breaks up into alcohol and carbonic acid gas. The best white malt is not heated to more than 190°, as the diastase is acted upon injuriously by a heat above that point. Maltose is a sugar which does not readily undergo the acetous fermentation, and, therefore, as Dr. Mitchell Bruce points out in his "Materia Medica and Therapeutics," "will not give rise to acidity and dyspepsia." This is a great matter, as the cane sugar the cook adds to stewed fruit and milk puddings readily undergoes the acetous fermentation in many stomachs. The lævulose sugar of fruit, like maltose, readily undergoes the alcoholic but not the acetous fermentation. Maltose being less powerfully sweet than cane sugar, a greater quantity is necessary to sweeten the pudding. If the raw starch, semolina, sago, or tapioca be first put in the dish by itself, and placed in the oven for an hour (taking care not to have it burnt by the oven being too hot), not only are the starch cells cracked, but a certain conversion of the starch into dextrine takes place. If to this be then added an equal quantity of ground malt and some hot milk poured on, and the dish be allowed to stand a few minutes before being put into the oven again, the diastase of the malt acts upon the farina and converts it into dextrine and maltose. Dextrine and maltose being soluble, the pudding is very thin. Such a pudding is admirably adapted for invalids and dyspeptics, as requiring scarcely any digestion in the body. For those with whom ordinary milk puddings produce acidity, such a pudding is specially suitable. Ground malt may be added to fresh milk, and forms an admirable food in cases of acute disease. Baked flour perhaps goes better with meat broths, to which it gives a high food value. (Well-baked flour requires but a touch of saliva to render it soluble, and, added to meat broths and gravy soups, renders them very nutritive.) Malt, being sweet, goes better with milk, or apple-water, or tamarind-water, or lemonade, and gives us a food which being all but independent of the digestive act, can be most usefully employed in the sick-room. Beef-tea (which alone is scarcely a food) and milk-and-seltzerwater pall upon the palate of the sick person, who craves variety just as do healthy persons. The adoption of ground malt as a food will solve for us one or two knotty questions connected with feeding people when the digestive power is feeble. Drinks like lemonade, made with malt instead of cane-sugar, would not only not go sour in the mouth and stomach, but would contain some phosphates and soluble albuminoids, and so form admirable beverages in pyrexial states. The many malt extracts now in the market are well adapted for such end.

## SOLUBLE GLASS OR SILICATE OF SODA.

In his "Manual of Alkalies," Dr. S. Pick says: —It has been long known that glass is a compound of silicic acid with alkali; the other combinations of silicic acid, however, with lime, e.g., were ignored as unimportant, until Prof. Fuchs, of Munich, showed (1818) that by the fusion of silicic acid a glass-like mass was obtainable, but which is soluble in water, and which he therefore named "water-glass." He indicated for its production the formula:—45 parts quartz powder, 23 anhydrous soda, 3 charcoal, fused together. Later experiments were made to replace the soda by cheaper sodic combinations. Kitchen salt, for instance, can be decomposed by silicic acid at a high temperature and in the presence of steam, when water-glass and hydrochloric acid are formed. Water-glass can also be produced in the wet way, by treating natural amorphous silicic acid, which is more susceptible to the action of alkalies, with some caustic alkali. Such an amorphous silicic acid is flintstone for instance. When pulverized and treated with a concentrated soda lye under ¼ atm. pressure, it is dissolved in the lye. Liebig proposed to employ fossil earth, which is found in large deposits and is nearly pure silicic acid, for the production of water-glass. According to his method, the earth is first calcined, in order to destroy the rest of organic matter; the earth is then completely soluble in soda lye; only a small quantity of sand remains undissolved and forms a small sediment with alumina, oxide of iron and lime. 74·5 parts crude, calcined soda are dissolved in five times its weight of water, and boiled with 56 parts, by weight, slaked lime or 42·5 parts quicklime. After the lye is brought by evaporation to 1·5 sp. wgt. 120 parts fossil earth are added; when 240-245 part swater-glass jelly are obtained, containing 46 to 47 per cent. dry silicate of soda, which consists in 73 per cent. silicate acid and 23 per cent. soda. At the time, when Liebig proposed this method caustic soda was not yet an article of general commerce, as it is at present. Nowadays it is more convenient, instead of preparing the lye of soda, to employ a corresponding quantity of caustic soda, and bring its solution to the above concentration. More recently silicate of soda is manufactured from the fossil earth, which is found in Hanover, as follows: Caustic soda lye of 1·22-1·24 sp. is mixed in a digesting apparatus with stirerr with so much calcined fossil earth, that the mixture contains 1 part sodic hydrate for 2·8 parts earth. Under 3 atm. steam pressure, the solution is complete in a few hours; when the lye becomes soon clear, a dark brick-red sediment being thrown down. Care must be taken, however, that no excess of silicic acid be employed, in which case a clear liquid is hardly obtainable. It is, therefore, only possible to produce a solution of water-glass of 1·18 sp.gr. If caustic soda lye of 1·30 sp. gr. is used, a water-glass solution of 1·22 sp. gr. is obtained, which requires nearly a week to settle. Finely powdered silicate of soda boiled with water is the solution which is known in commerce as "prepared water-glass," of 38 or 66°, that is, containing 33 or 66 per cent. solid silicate of soda. This solution is readily decomposed by acids, even carbonic acid, and gelatinous silicic acid is separated from it. It must be kept, therefore, in well-closed vessels.

Numerous ways have been suggested to utilise silicate of soda for a variety of purposes, but proportionately few have been found practical. On the ground of the fact that silicate of soda converts chalk and other porous substances into a hard mass, and that it forms a stone-like mass with caustic and slaked lime, it was supposed to allow of the employment of building material of inferior quality. An architect, however, will hesitate with right, to use material which must first be given the resistance which it does not possess by the aid of an artificial means. It has been adopted, however, to some extent, as a coating to give the plastering of houses more resistance against atmospheric influences. Experts, however, object to this usage, and have called attention to the circumstance that the ground, which was prepared with silicate of soda, for the first of the celebrated frescoes by Kaulbach in the vestibule of the museum of Berlin, is traversed by innumerable cracks, and that in some portions of the painting a white film is forming upon the paint. This is caused by the transformation of the silicate of soda into alkaline carbonate; which untoward circumstances renders also the impregnation with silicate of soda of building lumber impracticable, because the wood becomes by it more likely to rot. The same is the case with silicate of soda paints for iron, as they rather promote than hinder the oxydation of the iron. Only as a paint for theatrical scenery, rendering it less accessible to ignition, silicate of soda has been adapted without restriction.

As regards the use of silicate of soda in the manufacture of palm oil and cocoanut oil soaps, the opinions also differ. In this manufacture, 24-40-60 per cent. of a 35° B. solution of silicate of soda are added to the hot liquid soap on being dipped from the boiler, and vigorously stirred in until nearly congealed. It is claimed that the alkaline cebaceate, which in hard water causes the formation of an insoluble lime-soap, which settles upon the tissues as a greasy, yellow mass, hard to remove by injurious mechanical operations, is partly decomposed by the silicate which causes elimination of silicate of lime and free silicic acid, both which bodies are easy to remove by rinsing. Besides, the alkali contained in the silicate of soda acts by loosening grease and dirt. For this reason it is particularly recommended for wool-washing, giving a much cleaner product, as is asserted, than soap and soda. As another advantage it is claimed that silicate of soda does not cause felting of the wood, and can be applied, therefore, at a higher temperature. Silicate of soda alone cannot be used in clothes washing, as the silicic acid, which is separated in washing affects the yarn fibres. This evil is to be remedied by the commercial so called "composition of silicate of soda," or white soft soap. This preparation, however, is nothing but a solution of 1 part cocoanut oil soap in 30 parts heated solution of silicate of soda 39° B.; after stirring and cooling down it forms a soft soap of the consistency of a collection of little lumps.

## OPTICAL ANOMALIES IN CRYSTALS OF THE REGULAR SYSTEM.

The two well-known theories generally advanced to account for the action on polarised light, exceptionally exhibited by certain regular minerals, have recently undergone an important modification due to the discovery by Mallard, that sections of boracite, when heated above 265° C. (509° Fahr.), become perfectly isotropic. As is now generally known, Mallard, Tschermak, and their followers accounted for these optical anomalies by what is termed "pseudosymmetry"—*i.e.*, the imitation, by certain crystals, of a geometrical form of a higher grade of symmetry than they themselves actually possess, by complicated and repeated twinning. Klein, Krocke, and certain other German mineralogists, on the contrary, maintained that the optical peculiarities were produced, not by twinning, but by a molecular disturbance due to an internal tension caused by the irregular growth of the crystals. Klein had even succeeded in proving that the apparent twinning lines—the boundary between the areas of different optical orientation—could be made to move by raising the temperature, and the interpretation put by the same writer on the interesting observation of Mallard is very important, as offering a possible means of reconciling the different views which have hitherto existed regarding these anomalous optical phenomena. Klein suggests that the fact that boracite becomes isotropic above 255° C. proves that this substance is dimorphous, crystallising in the regular system above, and in some other, probably the orthorhombic, below this temperature. The crystals must therefore have been formed at a temperature above 265° C., and hence possess geometrically the regular shape; their internal condition is due to the effort on the part of the molecules to rearrange themselves in accordance with the altered conditions, which is strong enough to produce a profound optical disturbance, but is not able to pull to pieces the crystalline form. Boracite crystals at ordinary temperateratures are, in fact, a kind of paramorph, composed of optically orthorhombic portions enclosed in the regular framework in which the substance originally, at a higher temperature, crystallised.

Still more recently Klein has shown that leucite becomes isotropic at high temperatures, and Merian obtained a similar result for tridymite; thus it seems very probable that many other substances, like garnet, analcite, perofskite, senarmontite, &c., which show optical properties in no accord with their external form may be satifactorily explained by the assumption that they are dimorphous.

Another class of substances like potassium sulphate, leadhillite, aragonite, &c., whose optical properties at ordinary temperatures are in perfect accord with their crystalline form, have been shown capable of transference by increase of temperature to a state where their optical properties have a higher grade of symmetry, and consequently are no longer what the form would require, *e.g.*, both orthorhombic aragonite and monoclinic leadhillite become uniaxial when sufficiently heated.—*American Naturalist.*

## NEWTON'S FERROCYANIDE DEVELOPER.[*]

In November of last year, Mr. H. J. Newton, of New York, published the formula of a new developer, which differed notably in its composition from any other in general use by the photographic world. It was claimed for it, that it presented advantages in requiring only a minimum exposure of the plate, and gave full detail with plenty of density—in short, was a powerful yet controllable developer, and was a step in advance of most of the developers now in use. The formula is as follows:—

| | | |
|---|---|---|
| No. 1.— | Water | 9½ ounces |
| | Carbonate of soda | 480 grains |
| | Yellow prussiate of potash | 480 ,, |
| | Sulphite of soda | 160 ,, |
| No. 2.— | Water | 9 ounces |
| | Chloride of ammonium | 510 grains |
| | Solution of one drop of $H_2SO_4$ in one ounce of water | 1 drop |
| | Pyro (1 commercial ounce) | 437 grains |

For a plate 8 by 5, that has received a drop-shutter exposure take—

| | | |
|---|---|---|
| | Water | 5⅓ drachms |
| | No. 1 | 2⅔ ,, |
| Also | Water | 7 ,, |
| | No. 2 | 1 ,, |

Thinking it looked good, I determined to give it a fair trial, and, judging from an experience of it in photomicrography for three or four months, I am well satisfied with it. I have not tested it against Beach's potash developer, nor have I yet been able to try it in landscape work, but for photo-micrography it is admirable. The exposure appears shortened by fully one-third, and negatives abounding in detail, strength, and density are easily obtained. The colour of the negatives is not the nice black-and-white given by potash, but is of a strong olive brown, and very non-actinic. Owing to this fact, care must be taken not to push the development too far, or unduly dense negatives will result.

I do not wish to praise this developer as the "best," seeing how many good developers are already before the public, all of which give good results when used with intelligence; but I think the ferrocyanide developer has advantages in cleanliness and freedom from green fog, as compared with ordinary pyro and ammonia, and is more powerful, requiring much less exposure of the plate. During the cold weather of this winter I have found it work exceedingly well, and uniformly bring out brilliant and plucky images.

One word of warning: there are some makes of plates that will not stand this developer without fogging, unless bromide be used. The same may be said of plates that have received an excessive exposure. When I first tried the developer I got fogged images on several negatives in succession, and felt inclined to blame the plates, but for the fact that on one or two from the same box I got negatives of exceptional brilliancy. These, I afterwards discovered, had received the correct exposure, while the others were over-exposed and could not have been saved without the use of bromide. After this I found it best with every plate to start with two drops of a ten-grain per ounce solution of bromide of potassium, increasing the dose to six or eight drops if necessary. Using the bromide I found I could count on every plate turning out a success with a much shorter exposure than I had been accustomed to give—fully one-third less, and in some cases perhaps one-half—which is a decided advantage when working with artificial light.

---

# SCIENTIFIC NEWS.

ACCORDING to Dr. Gould, a star a little below the eighth magnitude, in the constellation Sculptor, has a large proper motion, his Cordoba observations for 12 years making its annual motion as much as 6·2″ in a great circle. It is numbered 1584 in Hour XXIII. of the Cordoba Zone Catalogue, and its place is R.A. 23h. 58m., N.P.D. 127° 59′. The largest proper motion in a star north of the Equator is that of Groombridge 1830—viz., 6.976″, as determined by Argelander in 1843.

The Rev. T. W. Webb, M.A., has published by Messrs. Longmans a little manual entitled, "The Sun: a Familiar Description of his Phenomena," which he thinks may be found serviceable in elementary instruction. It is an excellent little book, which may be commended to teachers and those who wish to learn. We hope it is to be followed by a series of manuals on the other members of the Solar System.

Amongst the after-Easter lectures at the Royal Institution there will be a series of eight "On Digestion and Nutrition," by Prof. Arthur Gamgee, on Tuesdays, April 14th to June 2nd; five lectures by Prof. Tyndall, "On Natural Forces and Energies," on Thursdays, April 16th to May 14th; three lectures by Prof. C. Meymott Tidy, "On Poisons in Relation to their Chemical Constitution and to Vital Functions," on Thursdays, May 21st, 28th, June 4th; four lectures by Mr. William Carruthers, "On Fir Trees and their Allies," on Saturdays, April 18th to May 9th; two lectures by Prof. Odling, "On Organic Septics and Antiseptics," on Saturdays, May 16th and 23rd. The following are amongst the probable arrangements for the Friday evening meetings: April 17th, Prof. S. P. Langley, "Sunlight and the Earth's Atmosphere;" April 24th, Mr. W. Carruthers, "British Fossil Cycads and their Relation to Living Forms"; May 1st, Lord Rayleigh, "Water Jets and Water Drops"; May 8th, Mr. W. F. R. Weldon, "On Adaptation to Surroundings as a Factor in Animal Development"; May 15th, Prof. Burdon Sanderson, "Cholera: its Causes and Prevention"; May 29th, Mr. J. J. Coleman and Prof. J. G. McKendrick, "The Mechanical Production of Cold, and the Effects of Cold on Microphytes."

Local scientific societies can now join the British Association as corresponding societies. The rules agreed upon by the special committee have been printed, and applications to be placed on the list should be sent to the secretary of the British Association for the Advancement of Science, Albemarle-street, W., before the 1st of June next.

The meeting of the Marine Biological Association at the rooms of the Society of Arts, which we mentioned on p. 101, has been postponed from April 13th to May 13th.

The Scottish Marine Station at Granton is progressing apace. In addition to the floating laboratory, the Ark, which is moored in the old quarry, premises have now been acquired on shore, and a building of two stories has already been converted into a laboratory and museum. It should be understood that the establishment is not a teaching station; it is intended solely for research, and to the extent of its accommodation is open to biologists engaged in such work. As lodgings are not readily obtainable in the vicinity of the station, it is intended to fit up one of the larger buildings recently acquired as a library, with several bedrooms and a dining room. The property was formerly a tanyard, and the pits are to be converted into aquaria. This summer a branch is to be opened for two months at Millport, and a trip will be made to the west coast for dredging purposes. Mr. Mill, the chemist and physicist at the station, is at present engaged in testing several new scientific instruments, amongst them a new anemometer devised by Prof. Crum-Brown and Prof. Chrystal, which is intended to be used for recording the force of gusts of wind on Ben Nevis.

A rather curious suggestion for rendering sea-water potable was made in a paper read before the Manchester Literary and Philosophical Society, by Mr. T. Kay, of Stockport. He proposes to change the chlorides by means of citrate of silver, leaving the sodium, potassium, magnesium, &c., in solution as citrates. Sea-water thus treated would be slightly aperient and diuretic if taken in large quantities, but would be suitable for moistening the parched throats of shipwrecked mariners.

An analysis of Dead Sea water has been made for the Rev. W. Allan, under the direction of Dr. Bernays. The specimen which was taken from the northern end of the sea, but not near the Jordan, was found to have a sp. gr. of 1·1528 at 15·5° C., and the total residue was equal to 15,260 grains per gallon. In round numbers the salts present were calcium carbonate, 70gr.; calcium sulphate, 163; calcium chloride, 594; magnesium nitrate, 175; magnesium chloride, 7,388; magnesium bromide, 346; potassium chloride 1,089, sodium chloride 5,106, and oxides of iron and aluminium 10, with organic matter, &c., 317 grains. The water was taken in the month of March; but in the autumn and further south, the solid matter is found in still larger quantity.

Mr. Reckenzaun's electric tramcar was tried last week on one of the South London lines. With some trifling alterations in details, the car will be perfectly successful from the mechanical point of view. The question to be determined is the cost of working in actual practice.

"The Moon and the Weather" is the title of a work by Mr. W. L. Browne, of St. Petersburg, which Messrs. Baillière and Co. will publish shortly.

A new volcano has been discovered in Russia. Twelve versts from the town of Ielna, in the Government of Smolensk, a hill is at present showing signs of volcanic activity. Ten years ago it was noticed that snow never rested on it, but melted away; and three years ago smoke began to issue from it, accompanied by subterranean rumblings. Lately, flames have shot up, and fragments of melted iron, cinders, and sand have been thrown up. A pole plunged in the ground was burnt up in a few minutes. All around the base rich grass grows, which is eaten with relish by the cattle. Indications of volcanic energy have appeared at two other places in the neighbourhood.

A discovery of platinum is announced from New South Wales, where it has been found in connection with gold in the Ophir district. Small grains have been found in considerable numbers in Hunter and Macleay districts, and at Wiseman's Creek, a nugget weighing more than half an ounce was discovered in connection with alluvial gold.

M. Berthelot publishes in the *Annales de Chimie et de Physique* for March a paper "Sur les Notations Alchimiques," which is accompanied by six plates describing the planetary signs, &c., by which the alchemists represented the metals.

**Gresham Lectures.**—The Mercers' Company have given notice that the lectures founded by Sir Thomas Gresham will be read to the public on the following days, at six o'clock in the evening, in the theatre of Gresham College, Basinghall-street:—Physic (Dr. Symes Thompson), April 14, 15, 16, and 17, geometry (the Dean of Exeter), April 21, 22, 23, and 24; astronomy (the Rev. E. Ledger), April 28, 29, 30, and May 1; divinity (the Dean of Chichester), May 5, 6, 7, and 8; rhetoric (Mr. J. E. Nixon), May 11, 12, 13, and 15; music (Dr. H. Wylde), May 19, 20, 21, and 22; and law (Dr. Abdy), May 26, 27, 28, and 29.

**Dr. Chandelon's Process for Detecting Strychnine.**—By this method the objects to be tested are chopped up very fine, and are mixed with an equal weight of gypsum entirely freed from water. After drying, the whole is pulverised, and thoroughly boiled with 90 per cent. alcohol, to which a little tartaric acid has been added. The alcohol is removed by distillation after filtration, the residue being taken up with boiling water, filtered so as to remove all fat, compressed to 1¼ to 1½ cubic inch, and mixed with gypsum. After stiffening and pulverising, the mass is treated with chloroform in Soxhlet's apparatus. The chloroform extract is brought to ¾ or 1 cubic inch, and there is added an equal volume of a saturated solution of oxalic acid in ether. The oxalate of strychnine becomes crystallised in needle-shaped forms, from which the strychnine can be isolated by ammonia. This method is said to have been successful in detecting minute quantities of strychnine, and to be likewise applicable to tests for brucine, narceine, papaverine, thebaine, aconitine, atropine, hyoscyamine, veratrine, nicotine, and coniine.—*Lancet.*

# LETTERS TO THE EDITOR.

*[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.]*

*All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, 332, *Strand, W.C.*

*All Cheques and Post-office Orders to be made payable to* J. PASSMORE EDWARDS.

*** *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks a vice from whence great inconveniences derive their original." —*Montaigne's Essays.*

## FULL MOON IN FEBRUARY, 1904: A CORRECTION — COLOURS OF SHADOWS—SCINTILLATION AND WEATHER PREDICTION—COLLIMATION—THE MAPS OF THE ORDNANCE SURVEY—STELLAR PARALLAX, BINARY STARS, &c.: A REQUEST FOR A TREATISE ON ASTRONOMY—LUNAR PERTURBATIONS — HUYGHENIAN EYEPIECE — EARTH'S LONGITUDE AT PERIHELION.

[24061.]—SEEING my letter 23998 in print in your columns on p. 77, I am lost in amazement at my own carelessness in replying to "Leo's" query (56131, p. 43). After writing my initial "March 1st" I seem to have calmly taken it for *January* 1st of the current year, and calculated from that! The calculation should, of course, stand thus—Between March 1st, 1885, and March 1st, 1904, there are 15 common years and 4 Leap-years—i.e., 15 × 365 days + 4 × 366 days = 6,939 days. Dividing this by the time of one Lunation, 29·5305887 days, we get 234·976 in the number of Lunations which will occur between March 1st, 1885, and March 1st, 1904, a number so very close to 235 that we see immediately that the Moon will be Full at the last-named date, a very little later than she was on the 1st ult.; and that hence, as during the present year, there will be no Full Moon on February, 1904. I hope sincerely that I have not misled "Leo," though it seems hard to conceive how anyone could read the + 61 days, without at once detecting the nature of the oversight and the consequent untrustworthiness of the result.

Without attempting to account for the turquoise blue shadows to which the first half of Mr. Gayler's query (56221) on p. 89 has reference, I think that the blue ones he noticed on his gas-lit paper admit of a simple explanation. Imprimis his newspaper was feebly illuminated by the steel-grey twilight, and superposed on this was the flood of yellow gaslight. Had the latter only existed as the source of illumination, all shadows would have been black; but when the overpowering light of the gas was screened from the paper, it was still sufficiently lighted to show the bluish tinge your correspondent describes. If we were to illuminate a whole wall by light passing through crimson glass we should, of course, see the wall red. If, now, though, we were to flood it with the electric light, the latter would so overpower the relatively feeble red light, that the wall would exhibit the whiteness almost of snow. It is quite obvious, however, that the shadow of anything intercepting the electric light would look *red*, and not black at all, until the first light was extinguished.

On more than one occasion I have invited attention here to the discovery made by M. Ch. Montigny, of Brussels, by the aid of his beautiful Scintillometer, that blue largely predominates in the twinkling of the stars when there is much water in the atmosphere; and that the preponderance of green, and more rarely of violet, is indicative of great dryness. In the Bulletin de l'Académie Royale de Belgique 3me serie. t. IX., No. 2, 1885, appears a paper by M. Montigny, which has been reproduced in a pamphlet form, which is well worth the perusal of all who are interested in placing meteorological prevision upon a scientific basis. The tables given in this latest work of the Belgian savant seem to render it certain that he has hit upon a law which reduces the prediction of a wet or a dry season to a very minimum of uncertainty. Perhaps the best test of the soundness of his views is to be found that his forecasts of the increasing drought in Belgium of the years 1883 and 1884 were fulfilled *au pied de la lettre.*

The Collimation error of "Rosicrucian's" Transit Instrument (query 56269, p. 112) is 1·61sec. on the Equator.

In thanking "A. S. L." for the information he has so courteously given in letter 24058 (p. 107), I may pretty confidently say that it will be of value to many a reader of the English Mechanic besides myself. But the very form in which it is given suffices to show with how much ease a sixpenny pamphlet might be prepared explaining the delineation of part of a spherical surface on a plane by de Thury's projection; the distinction between the true meridian of any given station, and a parallel to the prime meridian drawn through it, &c. By the aid of photo-zincography this might well be sufficiently illustrated, and yet be sold at the price I name. Depend upon it, very few possessors of the maps would fail to provide themselves with such a useful and, in fact, almost indispensable adjunct to their intelligent employment. I learn for the first time of the extraordinary policy of the Ordnance Department in increasing the cost of the maps to check the demand for them! I can remember nothing so much resembling this as the behaviour of the negro manager who, when pelted with bricks by an unappreciative audience, exclaimed: "If yer don't leab off trowin' dem bricks, I'll raise de prices, and den none on yer can't come in!"

I will try to deal in the best way I can with the extremely modest request of Mr. Arkwright, preferred in query 56309 (p. 113). How many hours (or even days) he supposes I am going to spend in getting the materials to reply to him in full; or how much of your space, Sir, you would of your kindness allow me to occupy, he scarcely seems to have taken into account at all. Here, to begin with, is a little table from Loomis, giving the parallax of some of the stars whose distance has been best determined.

| Star. | Mag. | Parallax. | Distance in radii of Earth's orbit. | Light interval in years. |
|---|---|---|---|---|
| α Centauri........ | 1 | 0″·92 | 224,201 | 3·54 |
| 61 Cygni ........ | 6 | 0·45 | 458,366 | 7·24 |
| 21258 Lalande .... | 8 | 0·26 | 793,326 | 12·53 |
| 17415 Oeltzen .... | 9 | 0·25 | 859,437 | 13 57 |
| Sirius ............ | 1 | 0·23 | 896,803 | 14·16 |
| 1830 Groombridge | 7 | 0·16 | 1,289,055 | 20·36 |
| α Lyræ ........... | 1 | 0·16 | 1,289,055 | 20·36 |
| 70 Ophiuchi ...... | 5 | 0·16 | 1,289,055 | 20 36 |
| ι Ursæ Majoris.... | 3 | 0·13 | 1,586,653 | 25·06 |
| Arcturus ......... | 1 | 0·13 | 1,586,653 | 25·06 |
| Procyon .......... | 1 | 0·12 | 1,718,173 | 27·15 |

On this subject the tables at the end of Newcomb's "Astronomy," and Ball's "Astronomy," should be consulted.

Here are the elements of some double stars:—

| Star. | T. | ☊ | π | i | e | a | P Years. |
|---|---|---|---|---|---|---|---|
| η Cassiopeiæ ............ | 1901·25 | 33°·20′ | 229°·7′ | 48°·18′ | 0·6244 | 8″·639 | 195·235 |
| Σ 73 ................... | 1798·80 | 57·54 | 142·9 | 41·39 | 0·6537 | 1·54 | 349·1 |
| 6 Eridani .............. | 1817·51 | 81·42 | 327·15 | 44 40 | 0·378 |  | 117·51 |

It would be the merest idle waste of time to compute the place of Spica Virginis "in Anno Domini 0" (whenever that may have been!), inasmuch as the idea that that was the Star of the Magi is utter stuff and nonsense. I must respectfully decline to spend a week in hunting up the Proper Motion of Stars; besides, I am writing away as hard as ever I can to catch the post. None of the Companions to Procyon, so far discovered, account for the irregularity of its proper motion.

In reply to "Resultant Force" (query 56270, p. 112), there is certainly more than one misprint or error in the sentence he quotes, inasmuch as, imprimis, it obviously refers to the Moon's orbit, and certainly not to the Earth's; and, in the next place, 238,800 is the radius, and not the *diameter* of that orbit at all. It is quite evidently so employed in Fig. 12. As the perturbing action of the Sun on the Moon is a differential one—*i.e.*, his pull upon her is greater or less than it is upon the Earth according to the position she occupies in her orbit, the reason for using the numbers given (of course, with their proper designations) seems perfectly apparent.

"E. B. F." (query 56275, p. 112), must get two plano-convex lenses, one of 0·45in. for his field-glass, and the other 0·15in. focus for his eye-glass, and mount them in a tube 0·30in. apart, with their convex sides towards the object-glass. A diaphragm must be placed in the focus of the eye-lens. It ought to be a pretty good 3in. objective to bear a power of 200, though.

"J. A." (query 56281, p. 113) will find that when the Earth was in perihelion at 4 a.m. on Jan. 1 of the present year, the apparent longitude of the Sun was 280° 18′ 26·0″. Hence the Earth's longitude must have been 100° 18′ 26·0″ at that instant.

**A Fellow of the Royal Astronomical Society.**

## DOUBLE STARS — HYPERION — THE MISSING PAIR Σ 1143.

[24062.]—The new pairs mentioned by Mr. Holmes (letter 24001, p. 78) are not in any of the catalogues of Sir John Herschel, the only observer by whom such faint and insignificant objects would have been likely to have been noted. The companion to Σ 1228 has not been noticed by anyone else. The distance of the close pair of ζ Cancri is now about 1·0″. For P. xi. 111, Hall gave 0·68″ in 1879, and Burnham the same in 1882. Seagrave found 1·16″ for Σ. 2054 in 1882, and Perrotin 0·75″ for O.Σ. 175 in 1884. The present distance of ω Leonis (Σ. 1356) is about 0·60″. A gentleman writes to me that he sees O.Σ. 175 well with 350, and ω Leonis with 450 on his 10½in. With, observing near London. I do not think it probable that Mr. Holmes really saw Hyperion. The faint object he noticed was certainly near the place of that satellite, then near its eastern elongation, but I doubt if he could see so faint an object three months after opposition. In most of the Washington observations, Hyperion is called "faint," or "very faint" with 26in. I found it very faint with 18in. near opposition, and I know no instance of its having been really seen with less than 15in. Dr. Meyer failed to see it with the 11in. refractor at Geneva, though he made careful observations of Mimas on several occasions.

I am much obliged to Mr. G. Knott letter 24035, p. 101), for looking up the place of Σ. 1143. Σ. himself seems certainly to have seen A double in 1851.

**H. S.**

## TEMPEL'S COMET.

[24063.]—It is stated in your Scientific News of Feb. 20th, on the authority of M. Gautier, of Geneva, that in consequence of planetary perturbations, the comet Tempel, 1867 II., will come to its perihelion at the end of June or beginning of July. In the Scientific News also for March 20, it is stated on the same authority that the same comet will be retarded through the action of Jupiter to the amount of 148 days. Now, I am at present unable to reconcile these two statements. The past perihelion passages have been 1867, May 24th, 1873, May 9. In the following revolution the comet did not approach near to Jupiter, so that the perturbations were small during that revolution, and the comet performed its revolution with a mean motion not differing much from the osculating value at the commencement of that revolution—namely, 1873, May 9th, which was 594·2″ (the diurnal motion.)

I have not at hand the exact time of perihelion passage in 1879; but from what has been said it would be somewhere about the beginning of May, when the osculating mean motion would not materially differ from that at 1873, May 9—probably a little less. Now, a retardation of 148 days would imply that the current period would be longer by that amount than that due to the osculating mean motion at its commencement, which would bring the perihelion passage about the middle of September.

Perhaps M. Gautier found the perturbations greater than he had at first supposed. If any correspondent can throw any light upon this, I should be obliged.

**W. C. B.**

## θ AURIGÆ.

[24064.]—In letter 24002, p. 78, Mr. Holmes calls attention to the difficulty in seeing the close pair of θ Aurigæ. He will find some letters on this object in the English Mechanic for Feb. 9th, 16th, 23rd, and March 2nd, 1883; but it may not be out of place here to give a short account of this interesting pair.

The close companion was discovered by O.Σ. with the 15in. at Pulkova in April, 1870; it having escaped the notice up till then of all other observers, including Sir W. and Sir John Herschel, South, Struve, (with the 9½ at Dorpat in 1826), Smyth, and O.Σ. himself in previous observations. The following are all the measures of this object which are known to me:—

A−B. Σ.'s scale.
O.Σ. 8·7° : 1·98″ : (2ⁿ) : 1870·25. 3, 7·6 mag.
„ 3·0 : 2·24 : (2ⁿ) : 1871·24. caret.
„ 4·9 : 2·22 : (2ⁿ) : 1872·76. „
De. 3·2 : 2·05 : (2ⁿ) : 1875·88. 3, 7·5 mag.
B bright blue.
„ 0·5 : 2·29 : (2ⁿ) : 1877·02. 3, 7·8 mag.
B azure or ash.
β. 5·4 : 2·08 : (3ⁿ) : 1878·59. 3,10·5 mag.
β. 4·1 : 1·80 : (3ⁿ) : 1879·71. 3,10·0 mag.

There are two other catalogued companions, C and D; both discovered by Sir W. Herschel. The principal measures of these are:—

A−C.
♅. : 35·3″ : (1ⁿ) : 1782·67.
„ 286·0° : : (1ⁿ) : 1783·73.
O.Σ. 290·9 : 43·29 : (1ⁿ) : 1852·12. 11·0 mag.
De. 292·6 : 45·18 : (2ⁿ) : 1876·24. 10·5 mag.
Fl. 293·3 : 45.50 : (1ⁿ) : 1877·79. caret.
β. 293·3 : 45·51 : (2ⁿ) : 1879 41. 9·5 mag.

A − D.
$H_2$. 352·3° : 125.05″ : (1ⁿ) : 1823·14. (15 mag.)
Σ. 350·7 : 123·42 : (1ⁿ) : 1840·16. 10·0 mag.
O.Σ. 350·3 : 125·10 : (1ⁿ) : 1852·12. caret.
Fl. 349·5 : 127·95 : (1ⁿ) : 1877·79. caret.
β. 349·6 : 127·10 : (1ⁿ) : 1880·05. 8·8 mag.

The changes in A−C and A−D are due to the proper motion of A. It is evident that A−B form a physical object: otherwise it would have been impossible to have overlooked so obvious a pair before, as the distance would have been 9½″ in 1783, 4″ − 5″ in 1823 and 1826, 2½″ in 1840, &c., if B did not share in the proper motion of A. B is probably variable; it could not have been below 8·0 in Σs scale in 1870, 1875-6-7, or De. would not have spoken so definitely of its colour as he has, and yet Burnham rates it much smaller than C in 1878-9. In November, 1823 Herschel saw C with South's 5in. refractor, though he had missed it in February of that year with the same instrument. He rates C, 10m. and B 9m. on this occasion (he had called B 15 mag. in the spring!) and speaks of another suspected star 11−12 mag. On examining the original MSS. of H. and So. a day or two ago, I found that this suspected star was evidently the same as the one referred to by myself in the "E.M." for Feb. 16, 1883 (letter 21065), in about 340° ± 50″ ±. It is curious that this has only been seen by Herschel and myself. The very faint one (probably not much above 12·0 Σ.) in 170° ± 50″ ± found on the same evening, has not been observed elsewhere, I believe. I am pretty sure of its existence, but it was very faint with my 6¼in. Calver. Smyth gives the colour of A as "brilliant lilac," De., white, deep yellow, and deep green, 1876 and 1877.

**H. Sadler.**

April 2nd.

## JUPITER—PARTIAL OCCULTATION OF SAT. I. BY SAT. III.

[24065.]—An interesting partial occultation of the 1st satellite of Jupiter by the 3rd was observed here on March 27th. At 11h. 30m. the satellites were seen close together on the following side of Jupiter, towards which both were travelling, I. being a little to the south of III., the disc of which latter was clearly considerably larger than that of the former, and it was evident that a partial occultation of I. must take place. As the satellites were both moving in the same direction, the motion of approach was but slow, being only that due to the difference between the velocities of the two satellites.

The first contact between the limbs took place at about 12h. 2m., and at 12h. 20m. the appearance was that of an elongated and somewhat wedge-shaped single satellite, the elongation at this time being nearly at right angles to the direction of the motion. From the small amount of elongation, it was thought that quite one-third of the diameter of satellite I. must be concealed behind the disc of III.; but though the discs were of a slightly different tint, it was not possible to determine the actual amount of this by reason of the extremely bad definition and small aperture employed. In a large telescope, and with good definition, the phenomenon must have been extremely fine. Occultations of one satellite by another are necessarily somewhat rare, as they can only occur when the planes of the orbits of the satellites pass through, or very nearly through, the earth. The instrument employed in the above observation was a 2¾in. achromatic, with a single lens eyepiece magnifying 102 times. **A. Stanley Williams.**

## SOLAR ECLIPSE OF MARCH 16, 1885—MR. PEARSON'S PARTIALLY-GRAPHIC METHOD OF COMPUTING ECLIPSES AND OCCULTATIONS—MR JOHN A. BRASHEAR—SILVERING TELESCOPE MIRRORS.

[24066.]—The solar eclipse was seen here under very favourable conditions, though the high wind made the air a little too unsteady for very fine work. The day opened cloudy, but the sky cleared with the rising sun, and continued so throughout the remainder of the day. The eclipse possessed unusual attraction for me, for besides being the first one visible here for about five years, it was also the first I ever saw through a telescope. In this connection, therefore, I have been very much interested in the new method of computing eclipses and occultations devised by the Rev. James Pearson, of Fleetwood, and recently communicated to your readers in these columns. This method has answered my purpose admirably, and although I have little or no acquaintance with mathematical astronomy, I found no difficulty in computing the circumstances of the eclipse for this place, which are as follows:—

Latitude, 42° 21′ 28″ N.
Longitude, 4h. 44m. 14s. W.

Elements.

I.

| | | h. | m. | s. |
|---|---|---|---|---|
| G. M. T. of ☌ | = | 6 | 14 | 24 |
| Equation of T. | = | | 8 | 37 |
| | | 6 | 5 | 47 |
| Long. West | = | 4 | 44 | 14 |
| Sun's hour angle | = | 1 | 21 | 33 |

II.

$\rho$ cos. $l$ = 9·86929
P = 1·75572  P = 56·98′
1·62501
2·
0·37499 = 2·371
Value of 10′ of arc = 2·371 inches.

III.

$\rho$ sin. $l$ = 9·82618
P = 1·75572
Cos. $\delta$ = 9·99986  $\delta$ = 1° 27·2′ S
1·58176 = 38·17′
Diff. of decl. ☉ and ☽ at ☌ = 48·01
☽ above centre of ellipse = 9·84′

IV.

X cos. D = 29·23′
Y = 9·36 ascending
Moon's semi diam. = 15·6
Sun's do. = 16·1
Sum = 31·7

Phases.

| | h. | m. |
|---|---|---|
| Eclipse begins...... | 0 | 20. |
| Middle of Eclipse .. | 1 | 46.2 |
| Eclipse ends ...... | 2 | 56.2 |
| Magnitude.... | ·531 | |

First Contact—90° from the North Point and 97° from the Vertex towards the west.
Last Contact—38° from the North Point and 0° from the vertex towards the east.

As to the accuracy of these figures, my observations, which were carefully made with a 6½in. silvered-glass reflector, will speak for themselves:—

| | h. | m. | s. |
|---|---|---|---|
| First Contact ............ | 0 | 20 | 6 |
| Last Contact ............ | 2 | 56 | 2 |

And the points of contact were, as nearly as I could determine, correct.

But not only is this method easy and accurate, it is also extremely expeditious. In computing the eclipse for Rochester, N.Y., for Prof. Swift, I took out the elements, made the drawing, and obtained all the facts in *less than twenty minutes*. This, when compared with the usual laborious method, is a great boon, not only to amateurs but to professionals as well, and I thank Mr. Pearson for the benefit and pleasure I have derived from it.

For drawing the ellipses I use a piece of thin sheet brass, through which, at the places where the ellipses corresponding to every 2°, and the abscissæ corresponding to every 10 minutes intersect, I have made holes just large enough to admit the fine point of a pencil. By laying this on the drawing, I can mark these points, and using them for guides, by the aid of a curved rule, I can easily and quickly interpolate the ellipse required.

The moon passed over several sunspots, occulting the first and largest one at 1h. 2m. 50s.

Your readers will doubtless be glad to learn of the much improved condition of Mr. John A. Brashear, who, it will be remembered, sustained so painful an accident recently. Though able as yet to do only light work, he is now recovering rapidly. He has just corrected a mirror for me; but I have had no nights sufficiently fine to try it on test objects. However, his work is too well known to need any words of commendation, especially from an amateur. I have had the pleasure of receiving a copy of his address, referred to by "F.R.A.S." (letter 23861), on "Critical Methods of Detecting Errors in Plane Surfaces," a paper replete with the most valuable information. In regard to silvering mirrors, I have tried the hints given by Mr. Brashear in letter 23533, page 238, with the best success. After taking the mirror from the bath, it was "sponged" under the faucet with absorbent cotton for five or ten minutes, then laid on its back, and the remaining water *blotted right off with clean blotting paper*. I think this a most excellent idea, and as the mirror becomes dry immediately, *there are no stains left*, and it saves lots of time.

**Chas. L. Woodside.**

Boston, Mass., March 26.

[24067.]—I inclose you a sketch of the eclipse of the sun as it appeared at our place on March 16. The first contact was observed 10h. 32m. 30s. a.m. The position of circle marked A represents the position of moon at 12m., and the other marked B is position at 12h. 28m. 30s. The last contact occurred at 1h. 29m. 20s., using 90 meridian or central time. The drawing from which this is made was obtained by using a 4¼in. equatorial refractor, with a white paper screen attached at such a distance from the eyepiece that an image of the sun was formed 9¼in. diameter. The first and last contact was observed by removing screen and looking through eyepiece giving power of 80 diameters. The inner circle represents the diameter of moon compared with sun. The moon was visible in this position to only a very small portion of our continent. **L. W. Loomis.**

Carrollton, Illinois, March 17, 1885.

## EFFECT OF THE PARTIAL SOLAR ECLIPSE OF MARCH 16th, 1885, ON THE READINGS OF THE SUN THERMOMETER AT THE NEW YORK METEOROLOGICAL OBSERVATORY, CENTRAL PARK.

[24068]—At mid-day, just before the commencement of the eclipse, Draper's self-recording sun thermometer of this observatory indicated a sun temperature of 92° Fahrenheit, while the self-recording thermometer in the shade at the same time indicated 33° Fahrenheit.

When the observation was at its maximum, 1.30 p.m., the sun temperature had fallen to 69°, while that in the shade was still 33°.

At the end of the eclipse, 2.50 p.m., the sun temperature had risen to 82°, and that in the shade to 34°.

It is interesting to note from the above facts that one half of the difference between the sun temperature, and that in the shade at the beginning of the eclipse is 29½°, while the actual fall of temperature during the eclipse as shown by the sun instrument was 23°. This is as it should be, for only about one-third of the sun was obscured. It is probable that if the eclipse had been total the readings of the two instruments would have been the same. **Daniel Draper, Ph.D., Director.**

## THE SOLAR ECLIPSE OF MARCH 16, 1885.

[24069.]—It is a satisfaction to learn that the recent solar eclipse was most favourably observed at most of the astronomical stations mentioned in my recent communication on the subject. I have been fortunate in obtaining the assistance of an intelligent amateur, Mr. Charles L. Woodside, of Boston, U.S., who has adopted the partially-graphic mode of computation of these phenomena, which I have recently devised, and has sent me the results at his own point of view, and also a newspaper cutting describing the particulars as seen elsewhere. From these sources I send you the following details.

At Boston, the partially-graphic calculation gave the following—

| | | |
|---|---|---|
| Eclipse begins.... | 0h. 20·1m. | Eastern standard time (5h. later than Greenwich). |
| „ middle .. | 1h. 46·2m. | |
| „ ends .... | 2h. 56·2m. | |

In his letter he says, "I first found the point of contact, and then as the time approached, an assistant called off ten-second intervals, with this result—

| | |
|---|---|
| Began ............ | 0h. 20m. 6s. |
| Ended ............ | 2h. 56m. 2s. |

The points of contact were perfectly correct, as well as the magnitude."

At Cambridge Observatory, the eclipse appears to have been computed and observed with greater accuracy and success than elsewhere.

The following is the result of observations as regards time of *first* contact:

Computed time, as reckoned by Robert Treat Paine, of Brooklyn, 0h. 35m. 17s. mean time, or 0h. 19m. 48s. standard Eastern time; ditto, as calculated by myself by the partially-graphic method, 0h. 35m. 37s. mean time, 0h. 20m. 7s. standard Eastern time.

Observation of Professor E. C. Pickering with the East equatorial, and eyepiece 316 diameters, 0h. 20m. 9s. observed time, 0h. 20m. 7s. corrected time.

Observation of J. R. Edmunds with 3in. telescope, 55 diameters, 0h. 20m. 19s. observed time, 0h. 20m. 14s. corrected time.

Observation of O. C. Wendell, with a 6in. equatorial telescope of 70 diameters, 0h. 19m. 59s. corrected time.

The following are the exact times of the *final* contact:

Computed time by Mr. Paine 2h. 56m. 5s. standard time, 3h. 11m. 34s. mean solar time.

Computed time by partially-graphic process 2h. 55m. 57s. standard time, 3h. 11m. 27s. mean solar time.

Professor Pickering's observation, 2h. 55m. 46s.
Mr. O. C. Wendell's observation, 2h. 55m. 55s.
Mr. J. R. Edmunds' observation, 2h. 55m. 35s.

The accordance must strike the most cursory reader as remarkably perfect. The details, I may mention, are copied verbatim from the *Boston Advertiser*.

During the progress of the eclipse Mr. W. H. Pickering, of the Institute of Technology, obtained a series of 27 very perfect photographs of the solar orb. The special purpose was, if possible, to obtain representations of the corona, from which scientific deductions might be made. The process was a repetition of that employed by Dr. Huggins, in England, for the same purpose, the results of which were regarded as of value, though hardly amounting to demonstrations. The atmospheric conditions were entirely favourable.

During the progress of the eclipse Professor Cross, of the Institute, gave his class an opportunity to observe the phenomena as reflected by means of mirrors, properly adjusted to present and steadily maintain a dark image of the sun upon a white screen.

At Washington, the partially-graphic computation gave (as reported in your columns) time of beginning, 23h. 57m. Washington mean time. To this we add 5h. 8m. 12s. for East longitude, and subtract 5h. for earlier time at Greenwich. The result is 0h. 5m. 12s. standard Eastern time. The *Boston Advertiser* says:—"The eclipse was first observed at 0h. 5m. p.m. to-day, standard time. Heavy clouds obscured the sun the greater part of the afternoon, so that but few observations could be taken. A fraction more than one-half the sun was covered at one time, and this was the greatest portion concealed during the afternoon." No account is rendered of the final contact, which we may conclude could not be seen. The calculated magnitude was 0·52.

At Phelps, N.Y., Professor Brooks, of the Red House Observatory, obtained a good observation of the eclipse at 0h. 6m. 11s. standard Eastern time.

At San Francisco no observations could be made by reason of cloudy weather. At Amherst, Massachusetts, Professor Todd secured a complete record of the eclipse at the observatory. About 50 photographs were taken. The last contact was observed by Professor Esty and others.

I have given these copious details in the hope that they may prove interesting to your many amateur readers, and encourage them to adopt a mode of calculation which is far simpler and easier, and quite as exact as any other known method, and one which they each appropriate to themselves.

**James Pearson, M.A., F.R.A.S.**

Fleetwood, April 2, 1885.

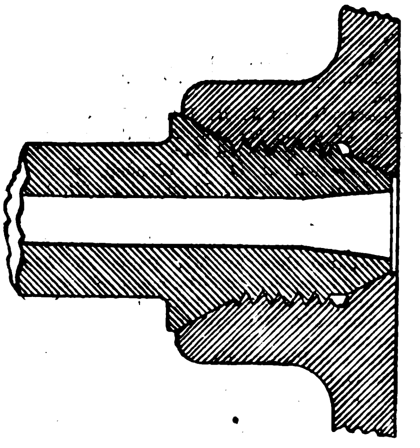
## THE SEASONS.

[24070.]—Whitaker, in his Almanack, states that spring, summer, autumn, and winter begin respectively on March 20, June 21, September 22, and December 21. There is probably an astronomical reason for this; but it seems to be hardly in accordance with popular, and to me, national, ideas for summer to commence on the *longest* day, and within a few days of Midsummer Day; for the middle of September to be regarded as in summer; or for autumn to expire only five days before Christmas Day.

I have hitherto looked upon Midsummer and Christmas Days (or to be more accurate, the longest and shortest days) to be the middle or height of their respective seasons. I shall be glad if any correspondents will give me their opinions on this subject, and if any can give hints concerning the etymology of the names of the seasons, and of the word "midsummer," they would throw useful light on the subject. **Devoniensis.**

## MANDREL NOSE.

[24071.]—I have inclosed a sketch section of mandrel nose; it shows another way in which a chuck could be made to run truly on any mandrel, provided the cones were the same. The distance from bearing to end of nose is 1¼in., but it could be made less by shifting the threaded part, if thought necessary. The cones are at the angle of 30°, and have a good biting surface in themselves, so that much of a thread is not required. Some may have an objection to this biting surface, on account of the difficulty of removing the chuck once on; this might be obviated by a coarser thread than the one shown, which is eight threads to the inch, and 1⅜in. outside diameter. This form of cones will give the chuck great solidity, as the front portion of chuck will be as firmly bedded on mandrel as the back portion.



This form of nose will also take up any wear, thereby removing the objection urged against the form of nose recommended by Dr. Edmunds.

**T. U. L.**

## LATHE MATTERS—TO MR. HINES.

[24072.]—In the most polite and respectful manner possible, I beg to suggest that it would be better for Mr. Hines to practise what he preaches in letter 23838, p. 521—viz., more carefully to read the contributions of other writers before writing himself, and in the most emphatic manner. I beg to deny that I have "*advocated* a long cylinder fit apparently as a substitute for the Edmunds mandrel faces," and beg to direct to his *more careful* consideration the remark in the first part of letter 23975, p. 61, and to remind him that he has not answered my questions therein contained. I would also ask him to show an error in the following reasoning, if such exists. Mr. Hines, in his letter 23838, says, Upon Dr. Edmunds' wide mandrel face there would be *no real wear*, nor upon his *short* but enlarged *cylinder base* (the italics are mine); but he says the wear on the *front portion* of a *long parallel cylinder*, combined with the wear upon the chuck, would be sufficient after a time to render its centrality imperfect. From this, one thing certainly can be deduced—viz., that if extra length is given to a cylinder, its life as a centring device will be shortened by reason of the wear on the front portion, combined with that on the cheek being increased; but I have pointed out before that for all practical purposes the total force with which the cylindrical portions of the chuck and mandrel are pressed against each other—in other words the origin of the friction between them—is determined by the weight of the chuck which would be increased so slightly by having its cylindrical fitting prolonged to, say, 1in., that it may be taken as constant. If the screw on the mandrel is an easy fit in the chuck, so that the cylinder is not hampered in its centring function, practically, the primary origin of the friction on the cylinder will be the weight of the chuck, and if the cylindrical fitting be increased in length, a slight augmentation in the weight will follow; but this will be so slight that we may neglect it and consider the weight constant. Now the ultimate friction will depend on the extent of surface which has to support this weight, and if the surface be *increased* fourfold, the weight, and *ergo* the friction, on any equal superfices, will be *decreased* to a like extent, so that here we have a decided gain. Can Mr. Hines prove me wrong? Since, then, it is not extra force with which the surfaces are rubbed against each other that makes the prolongation of the cylinder detrimental, what is it? Will Mr. Hines say there is only one other thing that could cause it, and that is the extra distance that the chuck has to pass over the mandrel cylinder base. If this is practically detrimental, the longer the cylinder the more would be the wear, and conversely the shorter the distance it has to travel, or the shorter the cylindrical base, the longer would it remain true, and this, if pushed to its extreme, would point to a cylinder whose length equalled only the thickness of a piece of tissue paper, as remaining true infinitely longer than that of Dr. E. This, on the face of it, is manifestly absurd, even if the weight on any determined superficies remained constant, which I have shown would not be the case, though at the same time I have not forgotten that the surfaces only gradually come into contact, and, as Mr. Hines points out, the wear on the first or entering portion—i.e., north portion of cylindrical base, and south portion of chuck, would bear the brunt of the friction, which friction never exceeds in magnitude that which the ·2in. base of Dr. E. will have to withstand. A slightly truncated cone of suitable angle would graphically depict the actions here. The slight truncation might be taken as representing the amount of surfaces in contact when, or just after, they first touch, and as these surfaces increase as the chuck is forced farther home, so the sides of the cone recede from each other till we reach the base, which might be taken to indicate the amount of surfaces in contact when the chuck was forced quite home against the face fitting; then, on the contrary, the slight truncation would measure the amount of friction on any particular amount of surface just before, or as the chuck reached its final position, &c. Working backwards, as the surfaces in contact decrease, so the friction would increase, as also does the distance of the sides of the cone from each other till the base affords us an idea of the maximum amount of friction reached simultaneously with the minimum amount of surfaces in contact; and, therefore, if the augmentation of surface to be worn away, accompanied by a diminution of friction, does not tend to *increase* the life of a lengthened cylinder, in the face of Mr. Hine's statement in letter 23838—viz., that the usage of a lifetime would scarcely affect the truth of a ·2in. cylinder, whilst a longer one, on account of its length, would, after a time, become imperfect. I consider that we are entitled to look to him for an explanation. I asked for this in letter 23975; Mr. H. has not given it; but, instead, made an erroneous statement, the result of too hasty reading and jumping at conclusions. In my letter (No. 23743, p. 431) I endeavoured to show "O. J. L." that, so far from the face fitting being so efficient as to be able to dispense with the centring properties of the cylinder, the reverse was really the case, and that a cylinder-fit sufficiently long would provide for the truth, both centrally and angularly, or in declination or equatorially; *but I did not advocate the use of it, nor have I done so since*, for, further on, I rather pointedly ask, "Of what use is it to propose for a moment a system which lacks any pretence to concentric adjustment," and concluded by voting in favour of a long cone-fitting as the proper basis of an interchangeable system. All through I have objected to the cylinder-fit, long or short, because it does not provide for adjustment for wear, and because I consider *two conical surfaces* offer less difficulty to the attainment of truth than *four surfaces in pairs at right angles to each other*. But I am glad to see that we are gradually reducing this matter to a nucleus, for a correspondent of "Ours," a very eminent lathe maker, states that he has used for over twelve years the taper, or cone, fitting as an interchangeable system for drills and centres, and *has found it to answer in every respect*, and this is no other than Mr. Hines himself. This places the cone, or taper, fitting, which *I have* been so strenuously advocating, on a very different footing, so far as regards this discussion, at once, and I am much obliged to Mr. Hines for the statement. It is now no longer a question as to whether the cone fitting will, or will not, answer. The experience of twelve years, with its concomitant friction and wear, has proved the system to answer in every respect for drills and centres; but it may be argued that it would be expedient to modify the dimensions of the cone system when applying it to larger and heavier chucks, such as increasing the diameter of the base of the cone, whilst retaining the same, or perhaps even reducing the length of it, and that under these new conditions the cone system would lamentably fail. No one would be more pleased to see this thoroughly argued to a correct conclusion than myself, and as Mr. Hines has admittedly had twelve years' experience in cone fitting, he should be well able to tackle this question in a critically scientific, and searching and lucid logical manner—not forgetting that it does not follow that because a certain angle for the taper has been found to answer for work of the dimensions of a lathe centre, that, therefore, the same angle *must* be used for all other apparatus; nor that the efficiency decreases in a ratio proportional to the increase of length, or diameter of the base, though no doubt there is a proper proportion which the length of cone should bear to its base to secure best results, and that certain different angles of conicity will be found best for different purposes—thus 4° seems to be best for one description of chuck for light work, and where the friction or jamming action alone is used to retain it in place, and the more obtuse the angle the less the friction. And here I would point out to Dr. E. that the friction of a moderately obtuse cone could be reduced much below his cylinder and face fitting by retaining the screw ferrule of "F. A. M.," or a modification of it, such as a ¼in. shoulder on the mandrel with a *left*-handed thread and boss at back of chuck, to be screwed with a right-handed thread and ferrule screwed to match, there would then be no difficulty in changing the chucks; but if the chuck was not secured sufficiently tight, the chuck, and with it the ferrule, would rotate backwards under the action of the tool, and so unscrew from the mandrel shoulder. Another plan would be to have right-handed screw threads on both mandrel shoulder and chuck boss, but of different pitches.

And now a word as to cost or trouble in making cone fittings. If work can always be turned true when mounted between centres, no matter what longitude they happen to occupy in their conical fittings in mandrel and cylinder, it can only be because the axes of both centres coincide, the prolongation of one with that of the other necessitating the truth of slot in bed, headstocks properly fitted thereto, truth of the mandrel, the centres themselves and of their conical fittings to mandrel, cylinder, and to the work. Such a conical fitting Mr. H. uses for a common, everyday chuck, like a centre may be considered to be; and yet I suppose that there would not be found one in a hundred good lathe makers who would not pay vastly more attention to the fitting of an expensive chuck, such as an oval, eccentric, epicycloidal, or geometric one, to its mandrel, than they would to that of a common centre—in other words, lathe makers would not choose an expensive system, but rather as simple and cheap a one as possible, for a *centre*, but would be more ready to lay out more time and skill on that adopted for expensive chucks. But since the cone or taper fitting as applied by Mr. Hines has answered in every respect for 12 years, it may be concluded that it is a thoroughly reliable and efficient means for the purpose, and not therefore necessarily unreliable on account of its cheapness and ease of production, else Mr. H. would not have continued to use it for so long a time. I have pointed out above the truth required in the various parts of the lathe if the truth of work is always to be relied on when turned between *centres mounted by the cone fitting*. The same accuracy would be required if the centres were mounted in any other way—say, for instance, Dr. E.'s cylinder and face fitting, and supposing that such a centre was the piece of work being turned, in addition to the above parts of the lathe, the traversing slide of slide-rest would have to be absolutely parallel with axis of mandrel and centres, and the surfacing slide as truly perpendicular to the same, else properly true cylindrical and face fittings could not be produced. On the contrary, for a male and female cone, the axis of centres must coincide in direction, but need not be parallel to the bed. Only one slide of rest will be used for the conical surface, the other being simply used to give depth for the cut as required, and one setting of the slide-rest will do for both cones, especially if the base of male cone is allowed to be north of, or farthest from, the mandrel, as then the largest diameter of hollow or female cone will be outside or north of holding chuck, and therefore its interior will be more easily getatable with the tool. Any untruth between the axes of centres and bed, or even slides of slide-rest, if such rest is not moved on bed between the finishing of both male and female cones, will affect the taper, but be equally communicated to both; and should the base of one be turned slightly less than it should be, such diminished diameter will be communicated to the whole of the cone, as the tool in slide-rest moves on, and the only result will be that the cone will have to be forced a little farther on its counterpart, and will then fit equally well. But if we had to make the chuck or centre fit up against a face, fitting as well as, and at the same time with, its cone fitting, then we should have to be very much more careful, as the slightest bit too much taken off the cone would allow the face fitting only to touch. Lack of centring means would then exist. If, on the other hand, we did not take enough off the cone, the face-fitting would never touch the chuck at all. The utmost care would have to be taken, and this extra amount of care it is that has to be taken with the Edmunds face and cylinder-fitting, as in the former case the cylinder would be too small to exercise its centring functions, if even a trifle too much were taken off; and in the latter you could not get the chuck on at all. Therefore, the cone-fitting is not only efficient, but easier and cheaper to make than the cylinder and face-fitting of Dr. Edmunds's mandrel. Then why adopt the latter in preference to the cone system?

In conclusion, if Mr. H. can construe what I have said, with reference to the cylinder-fit, into an advocacy for the use of a *long* fit of that description, then I am sure he is much to be envied; and I am proud to have engaged even his slightest attention for a moment; as undoubtedly he possesses ingenuity and inventive genius of the very highest order; but I fear he lacks an "eagle optic," and that his mind is not equally developed in the analytical direction.

As soon as time permits, I hope to write a line or two on the centring or de-centring properties of an angular screw-thread.

ERRATUM.—On page 61, column 2, line 41, for "about $\frac{3}{10}$ more pressure," read "·5858 or about $\frac{3}{8}$ more pressure." **E. J. S.**

## LATHE MATTERS.

[24073.]—IN reply to "E. J. S.," I have not written, because my practical knowledge is limited, and the theory is in better hands. A schoolmaster friend, who was talking of lathe-making with his boys, promised to help me in experimenting on Dr. Edmunds' mandrels; but as he cannot at present, I have little to say beyond that "E. J. S." and I seem to think a good deal alike, while he expresses our thoughts well enough for both. A few ideas have occurred to me; but I doubt if they are worth printing.

I do not object to the Doctor's nomenclature. We *must* define our terms, and if we had done so at first a good deal of talk would have been saved. "Angular variation" is the least obvious; but we have no corresponding astronomical term for this "axial inclination," though for variations in this angle we have, *i.e.*, nutation. After all, the nomenclature is conventional, and it little matters what terms are used, so that we use them for the same thing, and the advantage gained by using astronomical and geographical ones is that they are to a great extent defined by analogy.

As to the Doctor's mandrel, the theory is excellent; but the whole question must be submitted to the test of practice. In connection with this, I would call attention to Vol. XVI. p. 168, where is a letter from a correspondent (now dead) who proposes this same cylinder and face fit for the same purpose, and request "J. K. P." to comment on the design, which he did not do, to my great regret. In that case there was an internal instead of external screw, and one objection would be the large neck, while if used as an alternative for small chucks, I don't think it equal to the cone.

As regards the cone fitting, its great point is that it takes up wear or error in size, and so is superior to a cylinder in theory; but in practice, unless for small fittings, I doubt if it will come into use save in the disguised form of the screw-thread, which I feel sure for ordinary purposes will take some "rejecting." For centring, the cone should approximate to the cylinder; I doubt if the obtuse cone shown as a mandrel face in some back drawings has much value for this purpose; but this again is theory.

We are told that the screw is rejected as a centring agent. No doubt a cylinder pure and simple, or that series of cylinders called a cone, will enter more perfectly; but a screw centres well enough for ordinary purposes, and is the sole means of centring in the Holtzapffel nose, and that it answers as well as it does is due to its being a cylinder plus a cone, by which I mean that a square-threaded screw would centre perfectly while unworn, and a V thread does the same less perfectly, but allows for the small wear or error in fitting, which the square thread would not. We should notice, too, that the centring is done by the base of the screw, not the worn part at end, though even the base wears more than the Doctor's cylinder. I believe workshop convenience will settle this for us ultimately.

We amateurs reverence practice, and letters such as those of Mr. Wenham and "J. K. P." are as valuable as anything in the "E. M." Will Mr. Wenham say under what name (I suppose I must not say where) we should ask for it to obtain the mild steel he describes? Also, Mr. Hines might tell us if the steel with mild core is an ordinary article of trade, or is made from mild steel by carburetting, or how.

I noticed recently a small matter. In the sliding poppet, as the strain on barrel is upwards, why should the pinching screw be often placed on top or side? Whitworth's wedge is at bottom—the right place. Why, also, should not the steady pin be placed vertically upwards or downwards?

I should like to know what has been done lately in the way of systematising gauges and small screws. I borrowed a gas stock recently and got two taps, with result that I had two different threads, neither agreeing with my own. I should also like to know if the Holtzapffel lathe taps differ among themselves as much as the noses. Also, if Mr. Hines will tell us what makers finish their standard taps with laps, and describe the process? I don't doubt the fact, but ask for information.

Lastly, as regards cutting screws with circular cutters, "J. K. P." says (Vol. X. page 476), "I have used that plan on soft steel in making a pair of screws of 14 threads of 4in. pitch, with very capital results." Will he settle this point for us by a few words? **Bow.**

---

[24074.]—THIS discussion has had a great interest for me, and, enthusiast though I be, I must confess I am getting tired of the correspondence, and do not believe that the numerous letters which have appeared have led to any satisfactory conclusions.

To encourage the solution of the mystery surrounding the form of the projected standard model mandrel nose, I think it would be well if someone acquainted with American machine practice could be induced to give us the benefit of his experience. One has only to pay a visit to Churchill's and see what fine tools our brothers can send over to us, and we know that to manufacture goods of the perfection attained requires the finest machinery; I am, therefore, inclined to think valuable hints are to be obtained from this quarter. Personally, I am little acquainted with American practice, but am informed that they adopt for mandrel noses a large diameter, fine-pitched V-threaded screw running whole length of nose, and with no centring agent other than the form of thread, and but very little (about ⅛in.) of a collar at the root of the thread, the mandrel and nose finished in soft steel, and the front bearing a long parallel one. Now most of these fall in with my own views, excepting that I should adopt a cone bearing and coarser pitched truncated thread. The Whitworth pitch is what I take to be about right, but the thread would not suit; the form rounded off top and bottom means anything, and could not be relied on as a centring agent as can be done with a flat top and bottom or a V-thread. I do not know of any objection to increasing the size of the nose—say, 1⅜in. or 1½in. for a 5in. to 6in. lathe, and finishing soft, thus rendering the manufacture and interchangeability easy. Certainly soft noses are liable to be injured; but careful operators are mindful of their welfare. As for the neck being hardened, I do not see the necessity of this at all; a soft steel neck, running in cast-iron or phosphor-bronze collar, makes a beautiful bearing, and is all that can be desired in point of sweetness and durability, and I venture to think that no one who has used either of the combinations would care to make a change for hardened necks and collars.

The nose proposed by Dr. Edmunds appears to be good, and finds favour with me; but somehow seems to be getting along very slowly. The suggestion of a nose with two parallel cylinder fits, one at beginning and the other at end of thread, is also good; but I scarcely think it could supersede the existing pattern.

Will anyone oblige by suggesting a good form of light-running overhead gear for ornamental work in a 6in. lathe? My present arrangement is far from satisfactory.

One other matter. I should like to know how the alleged appearance of spherical turning is attained with the dome chuck you illustrated a couple of months ago? Will anyone knowing how, or possessing a chuck of this particular kind, oblige? Is the effect solely produced by the dome chuck and a fixed tool?

March 30. **A. F. H.**

---

[24075.]—I FEAR Mr. Wenham is rather inclined to make a mountain out of a molehill in the matter of Dr. Edmunds's slip.

A thread of 10 turns per inch on an inch nose, or others of like proportion, would show very little change from the angle 50° if cut by a wheel of that angle. It is not strange that it escaped observation on the samples exhibited, the which, I presume, were so finished.

Whether or not Dr. E. values the strict angle of his thread or the wheel process the more, or the latter at all, I cannot quite say; but if he values the wheel process, and is not strongly attached to the strict form of his thread, the comparative ease with which a 50° cutter can be made, and the facts that, though the threads in chucks and on nose would be different, the extra thickness would be on latter to resist wear, and also that the thread would be a little more upright, and thus perhaps preferable to the strict angle—as it has to avoid acting as a centring agent—make it appear that he has probably perpetrated an improvement. If the thread were described as one "formed by a cutting-wheel of 50° angle and truncated 7½ per cent. of its length," the position would be at least as good as before. The inaccuracies of a thread so cut might, I opine, be by comparison with the centring cylinder styled as medium finish, the centring cylinder being presumably of the highest possible.

Referring, I find I have misstated the nature of the deformation: the thread would be broader-topped, not broader-based—it is the cutter that should be the latter.

Looking at the question of forming the cutting-wheel of the true curve and shape, no particular difficulty presents itself. All that is necessary is to place the wheel, with faces roughed out, *in situ*, and to rotate it while acted upon by a tool in a slide-rest set to the angle of 50° or other desired degree in a horizontal plane, the tool-point being accurately on the line of centres, or rather, moving in the plane containing the axial centre of the disc. It would be an easy matter to make a special tool: with the disc between centres, a slide-rest of short traverse and angled to the centre line and horizontal according to the pitch of thread, and so as to occupy the same relative position as if the cutter were *in situ* and the rest horizontal, &c., would be all that is required.

Perhaps Mr. Evans intends to proceed in one of these ways. Two cutting bits would probably be required for the separate sides, one with more and the other with less than the usual clearance, &c.; but that is a trifling matter.

A screw-nose is surely a hopeless centring device; unlike the short cylinder, it is by many preferred fairly soft, and has to withstand the wear and nipping strains of all the chucks, together with the long travel over the outer end. The complexity of the surface is very great compared to the cylinder, and durability is out of the question, if transferability is not so altogether.

Dr. Edmunds, after perhaps some pretty hard hobby-riding, has well superseded the necessity for transfer chucks; other makers than those who have taken the mandrel in hand will, I fancy, be more or less necessitated to do likewise. That he has produced the best mandrel-nose, is still an open question; but if the threaded nose is to be retained, there is little, if any, room for improvement—in my judgment, at least.

I am afraid "E. J. S." would find it practically impossible to accurately run and exchange facially with the small taper of 10° he puts on his large diam. cones; it would be easier if the cones were of less diam., as the question is one of proportion of length to base for cones of such angles. I know myself from more than one uncomfortable failure.

Having some long large-flanged spindles in hand and a probability of more, the questions of annealing, forging, cutting from solid, &c., have lately been of considerable interest. Cutting from the solid could only be done economically for a short length to include bearing, &c., with a weld to tail end. I think, however, that by hardening and re-softening the mandrels in the rough before finishing for case-hardening, that swelling in patches, as is generally the case with forgings, will be avoided, as also the tendency to warp; the latter, of course, provided that the heating and dipping are done uniformly, say, in suspension. The broad-standard mandrel might be forged, and if similarly treated ought to rival the cut-out for not swelling. I have hardened steel pivots without dimming the polish sensibly, by putting them tightly in a metal hole. At first, I could not think they had been fired at all, though they were dead hard. If Mr. Wenham had offered a prize, there would have been a good chance to obtain it by these methods. **Vulcan.**

---

[24076.]—WHY should not Mr. Hines use the finest and best quality of cast steel if he can produce a true mandrel, which he cannot do by lapping, and so he must use the emery wheel, or the diamond, bort, or carbonado tool. Mr. Wenham quotes Sir

J. Herschel as having used the diamond (gem) for turning up hardened steel axes for his telescope. So did Dr. Robinson, of Dublin, and in this case the diamond is, or was a few years since, in the possession of Professor Stokes's family, the Professor having married Dr. Robinson's daughter. Dr. Robinson used the diamond (gem) in 1867, or before.

When Mr. Wenham speaks of the turning by the diamond, does he mean the gem (pure or impure), or portions of it which is a crystal, or part of a crystal, or does he mean what has been popularly, but erroneously, called the black diamond (which is often black, sometimes grey), and which is amorphous, and not crystalline. **Z. Y. X.**

## INTERCHANGEABLE MANDRELS.

[24077.]—MAY not what is wanted be summed up in this way?

A cone fitting (query, what is the proper angle?) to act as a guide to the chuck.

A shoulder to prevent the chuck jamming on the cone.

A screw (not necessarily good-fitting) to hold the chuck to the shoulder.

Of course, the difficulty (but far from unsurmountable) is to get the face of the shoulder on the mandrel to be just at the proper part of the cone, so that when the chuck is on (i.e., home) it just touches the shoulder. Then the screw gives the tightening up. **Z. Y. X.**

## DIAMOND TOOLS.

[24078.]—I HAVE to thank several correspondents for specimens of bort and carbonado and for references to descriptive data. To one correspondent I am indebted for the loan of specimens and tools of great interest for the purpose of examination and experiment. The tool in question takes cheerfully to a rat-tailed file, and it turns up green porphyry, cat's-eye, agate, and other indigestible materials easily. It is not a tool to give to a man who has much beer in him; but for an intelligent master at metal-turning, it may take a place that now much needs to be filled. For the shaping of certain surfaces in hard steel there can be no question that it may answer perfectly if the stone be of the right sort, properly set, and used discreetly. £3 or £4 for one slide-rest tool seems at first sight prohibitory; but as the tool, with proper usage, is said to never wear out, its cost in the first instance will be a secondary matter. I hope in the course of a short time to complete some experiments, and collect data which will be of value to our readers, and I will lose no time in writing again on the question. I shall then have the pleasure of publicly thanking my correspondents individually for their kind help.

The real fact seems to me to be that some of these stones are good for one sort of work and some for another, just as steel requires to be tempered and managed according to the purpose for which it is wanted. Then, again, the various methods of setting need to be discussed, and the right one for the stone and for the particular work needs to be secured. Stones which are bought in the same parcel at the same price, and under the same name, seem to me to vary as much as cast-iron (with or without the foundry scale), charcoal, and other irons and steels in their various states. Anyone who attempted to use these iron materials indiscriminately would be doing just about what many workers seem to me to be doing with these diamond tools, many of which are not diamond at all, and when they come to grief they blame the diamond, instead of their own want of scientific knowledge.

For the diamond slicer, I find that the charcoal iron disc is preferred by a most intelligent and able expert who is kindly showing me his methods. He says that none of the "mild steel" which he has been able to get proves to be sufficiently uniform in quality. The nickel he has not tried as a base for carrying the diamond teeth, otherwise he entirely concurs in what I have already written on the subject of the slicer. As to the milling-wheel invention, he showed me one constructed of a wheel which he had turned up in agate by means of a diamond, and had fixed in a slide-rest frame or handle precisely like the ordinary hand-milling tool. This he made eleven years ago; but it cut into a groove precisely as I predicted, and he threw it aside and reverted to a mass of agate held in his hand. At numerous points along the edge of his favourite slicer, I could feel with my nail fine diamond crystals sticking out of the metal, and these, when examined by a lens, were seen to be set just as definitely as the large diamond used by the plate-glass cutter is seen by the eye to be set. He laid great stress upon the fact that if a point ever gets set awry on the edge of the slicer, or if a point gets set on the side of the slicer, the instrument is spoiled, inasmuch as it will always work itself out of of line. He had found it next to impossible to get such points out of the slicer when once they had got wrongly imbedded. In using diamonds for cutting glass, he regards it as very important that the diamond should never be led a second time over lines which it has once cut. He says that the margins of the newly-cut furrow tear out the sides of the boat-shaped edge, and rapidly destroy the diamond. All intelligent glaziers keep, I believe, to this rule, but it is interesting for us to know *the reason why*. On examining with a lens a diamond crystal that has been taken over the cut a second time, we can see the abrasions which its side have undergone.

"Z. Y. X." is quite right in the points on which, in the "E. M.," he lays stress. He kindly writes me that the *Engineer* of Sept. 27, 1867 (p. 267) describes Dr. Robinson's turning up of his hard steel telescope pivots by means of a gem diamond. Will he kindly publish the extract in the "E. M.," and favour us with any further data he may have on the subject?

The questions we have to settle are, How far can the use of diamond cutters for hard steel be developed beyond the conditions of a laboratory experiment? and on what points does this possible development depend. **James Edmunds.**

Grafton-street, Bond-street.

## CUTTING SCREW-THREADS.

[24079.]—IN a question of grave practice, when a person resorts to coarse and senseless banter—as "red herrings" and the like—he heralds the weakness of his case. Further, I am said to be trying to "save myself from the dogs." What dogs? The application of this term to the writer of the sentence as one of the pack must be so evident, that it is inexpedient to disturb its significance.

I do not "run away" from my point. I selected the square and also the multiple thread of the "screw" or "skew gear" because the model of a milling tool turned to a template the counterpart of a section of the thread interval, on being tried therein, would at once demonstrate the cause of error to a screwcutter of the dullest comprehension. Similar causes of error will exist more or less in all screws cut with a circular cutter, whether V-threads or otherwise. Though I begrudge every word that I write on this point, so obvious to everyone familiar with workshop practice, yet I will quote a sentence from column 3, page 103, of last issue: "Instead of the revolving cutter being liable to give a distorted thread, it is the fixed tool that involves that liability, because it is difficult to keep its cut exactly upon the line of centres." (It must be a very indifferent workman that cannot do this.) It would be excessively difficult to adjust the inclined axis of the milling cutter in the line of centres. If in a right-handed screw it is set above the work, the thread will be lopped over to the left; if set under the centre, the cutter will lop the thread over to the right. Let anyone trace a spiral on a cylinder—say, a cedar pencil—hold a coin with its edge to the incline of that spiral, then shift it above and below the centre of the pencil, and he will realise what I mean, and the wretched abortion of a screw-thread produced by a wheel cutter is liable to this additional error! If the V milling cutter is employed to cut a concentric groove round a cylinder having the axis parallel thereto, it is of no consequence if the cutter is set high or low; but when it is inclined and employed for cutting a spiral, the conditions are entirely different.

I am invited to show where error is. Very well. The "beautiful screw-thread" of the "model mandrel," and also the collar bearing, are to be trued-up with laps or skives charged with diamond powder. This is another blunder arising from mere paper theorising. The gem particles are at once driven deep into the metal of the grinder, which also soon gets choked up with the abraded steel, just as a fine file does with lead, and ceases to abrade. I wish joy to the patience and pocket of the man that would constantly keep up a feed of diamond. In an emery wheel consisting of coarse particles, the abraded steel is thrown off and consumed as a shower of sparks, and so energetic is the action that under a deluge of water sparks are still there. Diamond in large pieces would be sufficiently strong to take a good shaving off hard steel; but for mere trueing-up heavy cuts are not required. The diamond will pare off the hard steel in fine, hair-like curls, and, more curiously still, I have seen a curled shaving taken off a surface of polished glass by a keen diamond splinter. A diamond turning tool may be sharpened on a lap or wheel, charged with the same material, like a steel tool on a grindstone. In this country there are but few workmen in the toolshops who know how to mount, or have any experience in the use of diamond cutting tools. Mr. Hines does not use them, and we must rely on the practice of those who do. I do not consider him answerable for all that he writes, for, to apply the suggestive metaphor heading this, he is hunting in couples. In the tenour of his writing he naturally strives to convey the impression that his house is the fountain-head of all that is excellent in practice; but it appears that he needs something more, for if in any form or detail he has hitherto been helplessly groping in darkness, a new light has now appeared to him in the shape of a "model mandrel," and it is to be hoped that his anticipated "clients" to be attracted thereby will have reason to rejoice at the change, for an ornamental lathe requires to be well considered. The late productions of foreign makers show that for substantial design and accuracy of finish they are quite up to the mark, and are turned out at prices that are not prohibitive.

Finally, as this screw-nose talk is likely still to drag on its weary length for months to come (if we are to judge from precedent), I have to say that, as every hour of my time is now occupied, I can only take notice of it at a convenient period when the eternal paraphrase on this small idea has become somewhat exhausted. In the mean time, if a V-thread screw of a size to be easily seen—say, eight threads on an inch barrel—is offered for my inspection, having been cut up with a milling cutter, together with this cutter, and which screw will bear the usual reverse and counter test, and have straight-lined angle faces, or the threads not hollowed by the cutter or lop-sided, then I shall have to admit that there may be something in it. This is a certain proposal for me to make, because, for practical reasons, a perfect thread produced by these means will not be forthcoming.

**F. H. Wenham.**

## DIAMOND FOR CUTTING TOOLS.

[24080.]—Mr. WENHAM must have heard or seen the carbonado almost immediately after its introduction into England. He says it came into the market *about* 35 years ago. That would be 1850. The first trace of its mention which I have seen is in 1852, only two years difference from the date given. **Z. Y. X.**

## METEOR.

[24081.]—LAST evening (April 3rd) I saw a fine meteor at 8h. 21m. G.M.T. ($\pm$ 1$^m$). I was walking along the street at the time looking at Algol, and so only saw it during the last few moments of its apparition. Its path, as observed, was from $\alpha$ 80° North $\delta$ 2° to $\alpha$ 76° South $\delta$ 4°, when it disappeared behind houses. Duration about three seconds. It seemed quite twice the brightness of Jupiter, and about 3′ diameter; colour, chrome yellow. No train seen.

Clapham, April 4. **H. Sadler.**

## LUNAR GLACIATION.

[24082.]—I HAVE to thank "F.R.A.S." for his remarks in 23774, page 472, of January 20th, even though they do not endorse my views, for I have the greatest difficulty, so far, in getting the theory examined by experts at all. I may also say there is often serious misapprehension over it.

An instance in point is where "F.R.A.S." believes I do not "sufficiently appreciate the extent to which the diffusion of aqueous vapour would take place in any sort of lunar atmosphere."

Properly speaking, the diffusion of aqueous vapour, in any lunar atmosphere, however rare, is a radical necessity of this theory, though the amounts and limits might not be identical on the moon and on our earth, in consequence of the different densities, due to the great difference in gravitation on the two globes.

But the absorption and diffusion of aqueous vapour would go on even at a temperature below zero, inasmuch as ice evaporates if there is air. The steady and slow decline of heat, and also of atmosphere, appears to have gone on simultaneously, and one feature of this theory is, that it seems to be a really beautiful demonstration of this decline, the air being viewed as the transporting medium for the aqueous vapour diffused in it.

Thus we see that the aqueous vapour raised largely (as in our case also) over equatorial seas, has been deposited on the Polar regions to form vast ice caps and the raised S.W. quadrant.

Eventually, as heat and transport failed, this aqueous vapour was deposited more closely around the equatorial seas, to form the vast raised regions around Mare Crisium, to north of Sinus Iridium and the great littoral highlands, such as the Carpathians, Alps, Apennines, Caucasus, &c.

Eventually, as heat and air as transport, still further declined, the aqueous vapour, raised from the lagoons left, or kept liquid by heat vents (as on our earth), was deposited still closer around, forming the ramparts of the walled plains and crater plains.

The circular lagoon formations gradually becoming smaller and smaller, as the ice crust thickened, the later ones often opening near those already laid and frozen, melted away their segments where they overlapped, and so on down to the "craterlets," about which time heat-energy was much reduced, and atmosphere very attenuated.

But contraction of the crust would still open deeper vents, by which some moisture from the warmer interior would reach the surface, and, failing to liquefy the crust, would simply pile as condensed deposit, often filling in old crater vents, as Linné, or even piling up cones like Pico, until at last the exterior would be so destitute of air as to become a practical vacuum, and aqueous vapour escaping would (steam-like) flash out into the void at enormous speed, and form the well-known haze or cloud of ice spicula, which, on subsidence forms the peculiar "rayed nimbus."

Whether this has been carried on yet another stage, to form the great ray systems, I cannot so far say; but it seems probable.

So that all through we see the diffusion of aqueous vapour in the lunar atmosphere, even when very attenuated, is a necessary element in the theory.

With regard to the question of the temperature of the lunar surface, after fourteen days' exposure to the direct solar rays, I can only infer it to be very low, and this part of the question, *i.e.*—the disproof of Lord Rosse's conclusions, is in far abler hands than mine. Both Professors S. P. Langley and C. A. Young are of opinion that the lunar surface temperature never rises as high as the melting point of ice, or even of mercury; and it should be borne in mind that Lord Rosse himself was not quite satisfied of the accuracy of his own conclusions.

The theory of lunar surfacing by glaciation seems to fairly well solve most of the peculiarities we see—*i.e.*,

1st. The absence of distinct Polar caps.

2nd. The difficulty *re* the total disappearance of the lunar seas.

3rd. The distinct relation (except in the case of nimbi) between the brilliancy and the inclination of surface in the detail, as though gravitation removed a darker coating on inclines.

4th. The very suggestive arrangement of the "clefts" around, or near, areas of presumed subsidence, as though they were cracks.

5th. The extraordinary coincidence of eight distinct features, held in common by the circular forms, from Mare Crisium down to the smaller craterlets, detailed on page 198 of "Ours," Oct. 31st.

6th. That the mountain ranges should be so generally littoral and segmental in plan.

7th. That craters and crater plains, and walled plains, are really all excavated forms, the material in some cases 5,000, 10,000, or even 20,000 cubic miles, being removed and piled around to form the walls, leaving the deeply-depressed inclosure a plain and level.

It also offers a fair explanation as to the formation of strings of craterlets, terraced craters, bays of all kinds; and the fact that craters near a sea margin have the wall on the land side the highest. It also explains the ridges on the so-called seas.

Apart from these, it also seems to offer a more reasonable termination of the life-history of a globe, a solidification due to the dissipation of its heat, a surfacing by glaciation, and where the Polar ice-caps have closed over the equator, instead of a final surfacing by igneous phenomena, and volcanic outbursts, and lava lakes.

I trust that "F.R.A.S." will yet give the subject some attention—it is a question of absorbing moment. For ages men have pondered over the great problem of "the end of the world." What is it to be? What, in the far future, is to be the end of our race, and the end of all life on the earth?

It seems to me we may read the answer on the face of our satellite, far off, no doubt, but certain in the end—universal death; while the great hymn of life will be taken up by other worlds, and sung in other words, the great sun itself at last teeming with life, in utter darkness, as the will of the great "All Father."

"It maketh and unmaketh, mending all;
What it hath done, is better than hath been;
Slow grows the splendid pattern that it weaves,
Its wistful hands between."—("*Light of Asia.*")

**S. E. Peal.**

### PROPER FORM FOR BED-FRAMES.

[24083.]—ON reading the letter of "Calm Repose" (23789), I thought the idea seemed so rational that I determined to try his plan, and accordingly I raised the head of my bed about 7in. (by means of bricks under the legs). Since then I have certainly been less troubled with vivid dreams, or indeed, any at all worth mentioning. I find it necessary to have a firm support for my feet (I use three or four volumes of the "E.M." as the most *solid* things I can lay hands upon), as otherwise I find there is a tendency to slip further down the bed than is quite comfortable.

As an invalid, I am not in a position to judge fairly the sleeping merits of the arrangement; but I find that I am able to get off to sleep much quicker now than I used to.

**Devoniensis.**

### AMATEUR MICROSCOPE CONSTRUCTION.

[24084.]—VALUABLE instructions have appeared from time to time in the "E. M." for making almost everything within the range of amateur work; but, with the exception of some articles (to the best of my recollection incomplete) in the older volumes, no full detailed instructions have been given on the construction of the microscope. Whether this arises from the fact that the mechanical exactness and optical knowledge required are practically beyond the skill of any but a professional workman, or from other causes, I do not know. I do not suppose that even the most skilled amateur could successfully make one with high powers, or of a complicated kind; but I should think that a serviceable plain instrument would be within the power of one who is fairly skilful at the lathe and metal work. I feel sure there must be many of our readers who would be glad to be in possession of this useful instrument; but who do not possess, or who do not care to spend, the money to buy one, but who have both time and the means to attempt its construction, if it could be done with a fair chance of success.

Would Mr. Wenham or others who have practical knowledge on the subject enlighten us upon this point, and if considered to be within the range of amateur work, may we venture to hope that shortly a series of articles on the "Construction of the Microscope" may appear in these columns?

**Nemo.**

### THE CASSEGRAIN.

[24085.]—DR. ROYSTON-PIGOTT'S letters are giving information which is not to be found in books, and which I had sought for in vain, so it is needless to say they are of special interest. As regards the distance of the convex from the concave, it becomes obvious why their sidereal foci ought not to coincide, if we remember that the sidereal focus of the small mirror is for *parallel* rays, whereas when in position in the telescope it receives *converging* rays, and this, of course, applies to the Gregorian as well as to the Cassegrain.

I do not, however, remember to have hitherto seen any formula such as Dr. Royston-Pigott gives for determining this distance. I have not my note-book at hand with the results in actual figures; but I have found that even in small instruments the distance apart of the mirrors differed very sensibly from the sum (or difference) of their foci.

It will be observed that, by omitting the divisor in the first term of the formula, we obtain the equivalent Newtonian focus irrespective of the eyepiece.

$$N = F \times \frac{f}{x}.$$

This in one of the cases given is—

$$N = 129 \times \frac{25 \cdot 8}{4 \cdot 96} = 671\text{in. (nearly)}$$

Or practically 56ft., as mentioned in the last paragraph but one.

I would ask Dr. Royston-Pigott if he can kindly give a formula to determine at what distance behind the great mirror the conjugate focus of the small mirror falls, or, in other words, where would the image be formed if the eyepiece were removed?

**A. S. L.**

### MINERAL-OIL LAMPS.

[24086.]—I DO not pretend to any scientific knowledge, so I only wrote of mineral oils as a practical man, having in the first place verified by actual experiment all I advanced. Very possibly I confused the terms, and I am much obliged to Col. Shakespear for setting me right. My meaning, however, must have been patent to every reader.

I never desired to convey "grave dissent from Sir Fredk. Abel's opinion," being convinced that the deliberate conclusions of such a master must be accepted. Nor did I at all question the principle he advocated; I only stated that "while lamps are made in their *present form*, a general adoption of his views might, in ignorant hands, lead to disaster."

Theorists cannot always as easily submit their views to a practical test as in the present instance is open to Col. Shakespear. He will confer a favour on all interested by providing his "*two* lamps in all things *identical*"(?), and after burning them at full combustion—say, for four hours—inform us of the then respective temperatures of the remaining oils.

As to his "6d. lamps of tin," the use of such is no proof that the principle is either right or safe. I have been familiar with the form of every kind of lamp, here and on the Continent, commercially made during the last 40 years, from the old camphine to the newest lamps of the present day, and I am convinced that the cheap (?) lamps have brought discredit on mineral oils. They are used by the poorest and least instructed. They are often charged with the lowest priced and worst oils, and to their structural imperfections must be added the gross ignorance and carelessness of the majority of their users.

I have also had great experience in the use of these oils, and have always found them (when properly managed) the best, cheapest, and cleanest domestic lights; and when Sir Fredk. Abel and Mr. Redwood have concluded their investigations, I have not the least doubt that from their instructions lamps will be constructed so simple and so safe that the use of these illuminants will be almost universal.

**J. Hughes.**

### CURIOUS OPTICAL EFFECT.

[24087.]—I HAPPENED to have a new smooth-bore breech-loading fowling-piece in my hands, and in looking through the barrel to see if it was well bored, I noticed an optical effect which interested me, and which I supposed to be an excellent example of diffraction bands.

The barrel was very smooth and well polished, the far end appeared as if terminated by a blunt cone formed of two concentric rings, leaving an opening of about one-fourth the real size. Following these two rings were four others the full size of the bore, alternately dark and light, sharp and well-defined.

If I am wrong as to the cause, perhaps some fellow-reader will take the trouble to set me right.

**R. S. Culley.**

### THE EMPLOYERS' LIABILITY ACT.—NOTICE OF INJURY.

[24088.]—I HAVE so often been consulted by injured workmen, anxious to claim compensation under this Act, but who, by omitting to give the necessary notice, had lost all chance of so doing, that I think a few words upon the point may be of practical utility. It is a needful principle in the administration of justice that everyone knows the law, for if ignorance of the law could be a valid plea, no one would ever be convicted. But in cases like this, where a statute makes a technical point and imposes a condition precedent to the support of a just claim, hardship is often worked because of this ignorance. Nowhere has this been proved more plainly than in regard to notice under the above Act. A Bill has several times been brought into the Commons by Mr. Burt and others to give judges some discretion where this notice has not been served within the stated period; but it has hitherto failed to pass, although some such amendment is certainly needed.

The Act provides that no action for the recovery of compensation for injury shall be maintainable unless notice of that injury is given within six weeks, and the action is commenced within six months, from the date of the accident. If the workman dies, then the time within which the action may be commenced is extended to twelve months from the date of the death. With regard to notice also death makes a great difference, for while the workman's action for injuries is gone entirely unless the notice is given within six weeks, yet if he subsequently dies the right revives. This results from the provision that in case of death the want of notice shall be no bar to the maintenance of the action if the judge is of opinion there was reasonable excuse for its omission, which appears to be entirely left to the judge's discretion. If this clause applied also to the case of injury without death, no harm could be done to employers, and some injustice would be prevented.

I am now dealing only with the ordinary case of injury when it is not fatal. Within six weeks from the day of the accident the workman must give notice to his employer. This time is to be reckoned in the usual way, and exclusive of the day in which the act was done, from which it is to be dated. Thus, if the accident occurred on Monday, 30th March last, the notice must be given on or before Monday, the 11th May, and that would be the last day in which it could be given. The notice must be in writing. Verbal notice is useless; the facts that the employer was present at the time of the accident, or knew it from his men, or even offered, or has actually paid, some compensation, are each and all of no avail. Written notice must be proved by the workman before he can begin his case; unless, indeed, this is waived by the employers at the trial. Although the notice must be in writing, it need not be actually signed nor follow any special form. But the Act provides that it shall give the name and address of the person injured, and shall state in ordinary language the cause of the injury and the date at which it was sustained, and shall be served on the employer. The name and address should be full and true. It is as well to set out the Christian names, but initials would be sufficient. The address should be the residence, and not merely a place of employment. By the "cause of the injury" the Act really seems to have meant the cause of the accident, because that is the true point, and the actual proximate cause of injury is not so material. It has been held that it is not essential to set out the exact cause of action, even if it were a paper drawn by a pleader, but that the notice must show the employer what occurred in such a way that he may be able to make proper inquiries, and so come to trial prepared to meet the plaintiff's case. Then the true date must be stated, but a mistake in this point would not be fatal. The Act, indeed, declares that a notice shall not be deemed invalid by reason of any defect or inaccuracy therein, unless the judge who tries the action thinks the defendant was prejudiced in his defence by such defect, or that it was for the purpose of misleading. This clause thus confers a discretion upon the County Court judges, before whom all these actions must be brought, as to the form and contents of the notice, although it does not enable them upon any statement of fact to dispense with it altogether.

Thus the notice must be served upon the employer, and this service must take place within the six weeks mentioned. It may be served by delivering it at the employer's residence or place of business. But this should be done in such a way that it will come to his knowledge in the ordinary course, and it should be left at a shop or office during business hours. But the other plan given by the Act, of service by registered letter, is safer where there is likely to be any dispute or confusion. To do this, the notice must be placed in an envelope addressed to the employer at his last known place of residence or business, and then registered and posted. Upon proof that it was properly addressed, and upon production of the ticket of registration, the notice will be considered as legally served at the time when it should be delivered in ordinary course of post, even if it never reached the employer at all. A company should be addressed at its registered office; although any one of the offices of a company or corporation that had several would seem to be sufficient. It is always wise for the workman to keep a copy of the notice he sends and of the envelope as addressed, and he should sign the notice as he would a letter. It is also wise to let the notice be drawn and delivered as soon as possible after the accident, as the time allowed soon slips away, and unforeseen circumstances occur causing it to be forgotten or overlooked until too late. I have known cases in which injured workmen have been kindly helped by their employers during the first seven or eight weeks after the accident, and then dismissed, the poor fellows only then finding out why they were thus treated, and only learning after the time had gone by that it was too late for them to give notice, without which their claims were irretrievably barred.

I hope soon to return to other practical points upon this Act, of interest to both sides; and can now again answer ordinary legal questions.

**Fred. Weatherfield, Solicitor.**

2, Gresham-buildings, Guildhall, E.C.

### GREAT WESTERN RAILWAY.

[24089.]—Mr. John F. Lawrence is wrong in thinking that the G.W.R. main line west of Bristol is wholly broad gauge. The 4ft. 8½in. gauge has been laid for some years now as far as Exeter. It has been and is largely used for running narrow gauge trains over.

About a year ago a loop line of about three miles was formed between Bleadon and Puxton (which are on the main line, about twenty miles west of Bristol), taking in Weston-Super-Mare, which had, before, to rest satisfied with a junction line between it and the main line, about a mile distant. The loop itself is laid narrow-gauge only, while the original line remains both gauges, and is used chiefly by two or three broad-gauge expresses each way daily, while most of the narrow-gauge stopping trains use the loop line, thus putting Weston partly on the main line.

The line west of Exeter is broad-gauge, with exception of a part of the branch line from Plymouth to Launceston, over which the S.W.R. main-line trains have running powers. **Devoniensis.**

### NEW MIDLAND ENGINES.

[24090.]—Thanks to "Helvellyn" and "Vortex," p. 84, for their opinions on the "big" engines. A sudden change has been made in the working; the Scotch expresses from London are now worked with the old engines 63 and 101, in place of 1675, 1676, and it is now admitted that the "big" engines can't work these trains. They have tried every move to get steam with the small boilers. Inspectors have ridden with them, even Mr. Johnson, jun., has been with them, and the final result of it all is that they are taken off Scotch traffic at the present. I expect the engines will do no good till they have new large boilers.

**Locomotive.**

### ANOTHER BRAKE FAILURE.

[24091.]—Would "Meteor," or any other railway correspondent, kindly explain the cause of a recent failure of the vacuum brake? The Midland 5 p.m. express from Manchester to St. Pancras, due in London at 9.45, 27th March, was made up of two engines and a very long train. Instead of stopping at Kentish Town it ran completely the whole length past the station, and had to be set back. It was a good thing there was nothing in the way; but such cases are very risky.

**Anxious to Know.**

### LEICESTER AND SWANNINGTON RAILWAY.

[24092.]—Since my letter appeared, p. 58, letter 23966, I have received several communications from correspondents asking for more minute details relating to the gradients and height above the sea, &c. I therefore inclose a copy of the Company's Official Table, which I made at West Bridge Station, Leicester, June, 1867.

**Clement E. Stretton,**

(Original Table Signed) Robert Stephenson, Engineer.

### "ENGINE-MAKING AT HOME."

[24093.]—Permit me to offer my thanks to your esteemed correspondent, "J. H.," for his interesting and able instructions concerning the making of small steam-engines by amateurs. Numbers of us are desirous of possessing a motor sufficiently powerful to work at least one lathe, and would go to considerable trouble and expense to attain that object in a suitable way; but a difficulty generally presents itself beyond the engine altogether—namely, the raising of steam. Of course, this can be done in the usual way by means of a coal or charcoal furnace; but has it not occurred to us all that coal firing is extremely troublesome. I think it is dirty, and the smoke is not easily disposed of. Can it be done by gas—that is, a gas fire or stove? Would not gas firing be extremely clean, ready, and free from trouble? Would it not, in fact, render a steam-engine almost as manageable as a gas-engine. I suppose it has been and is done. Then why do so many of us use coal at all? As we have had described to us the construction of the cylinder for a small engine, I would like to ask "J. H." a question or two on this point. Why is it that the simple double-action oscillating cylinder *without slide valve*, so much used in models, is not used for larger engines—say, for an engine of ½ or 1 h.-p.? Is it not cheaper to make? How does it stand wear? Will your obliging correspondent say what rate of speed a small engine—say, 1½ × 3in., could be caused to attain? Could it be driven by a moderate pressure—say, 10 to 30lb. square inch, at a speed of 1,800 revs. per minute? Is there a limit to the velocity attainable, pressure being provided in any required degree? If an ordinary cylinder could not be driven at this high rate of speed, what kind of a cylinder would be suitable for that purpose? Would someone who possesses an engine approximately of the above size kindly try the experiment so as to ascertain whether a speed of even 1,000 could be attained? **X.**

### DYNAMO.

[24094.]—I shall have much pleasure in giving "Anglo-Dane" (letter 23996) all the information he may require. I am very glad he is not going to make the machine, of which Mr. Bottone gave him some particulars, as it would most certainly have been a failure. "Anglo-Dane" will grasp my meaning when I tell him that the resistance of the armature would have been from 80 to 100 times too high. Apart from the question of resistance, the form of armature described is quite unfit to be used in a large dynamo: to be of any practical use, it must be laminated, and even then the vibration of the armature, caused by the jerk which it receives as each cog passes the ends of the pole pieces, is very annoying if the machine is in a workshop. With regard to "Anglo-Dane's" query (55839) he must remember that if the dimensions of a dynamo are doubled it will hold eight times the weight of wire. A machine to be self-regulating must have shunt and series winding in a certain proportion, which proportion must be determined by experiment; but if the resistance of the armature is low, a shunt-wound machine will be self-regulating within certain limits. For instance, if 25 per cent. of the lamps were turned off, the rest would not be materially affected with the addition to the machine of a resistance the amount of which could be varied by an attendant. The machine could be made to light any number of lamps, from one to the largest number the machine will light. I will next week send some leading dimensions of a machine which will light any number of 20-c.p. lamps up to thirty, which number might be easily carried to fifty or even sixty if the dynamo is only required to run a short time—say, for two hours; but, of course, in practice it is not usual to run a dynamo up to its full power, and I only mention the fact to show that I do not overrate the capabilities of the machine in mentioning thirty lamps as its useful output. I may mention now that the armature will be 8in. diameter by 8in. broad, and that it will have only one layer of wire on it. The core of the armature and the iron of field magnets will be very massive, so as to obtain an intensely powerful field in which to rotate the armature. I have been much amused by the correspondence which has taken place in connection with laminated armatures. I can assure the readers of the "E. M." that after taking into consideration the extra trouble required to wind it, the laminated Siemens H armature is still by far the best armature to use either as a dynamo or as a motor. Mr. Chaster, in letter 24041, is no doubt very funny; but at the same time not very scientific. Mr. Walker evidently made a mistake, either in the number of discs on the shaft, or, what is more probable, in their thickness, and out of this slight mistake Mr. Chaster tries to make a case against laminated armatures. Readers must be aware that the 150 discs would not be perfectly flat, and so, when put on the spindle, would be springy, and would naturally require a considerable amount of screwing up before they would be perfectly flat and square one against another. In his last article on motor construction, Mr. Chaster makes two statements I should like explained—first, what is carburetted annealed iron. I always understood that the purer the iron the less carbon it contained; and also, what is this battery that ran Mr. Jones's armature for several hours without suffering any diminution of strength. Perhaps it will be described in an early number, and then we shall probably read that this wonderful battery is manufactured by So-and-so, by Mr. Chaster's kind permit.

Coventry. **W. H. Eaves.**

## LAMINATED ARMATURES.

[24095.]—I am very sorry to see letter 24041, by Mr. J. Chaster. In the first place, referring to my letter, 23410, Vol. XL., the 150 discs mentioned therein should have read 110: this is probably a misprint, which had certainly escaped my observation until Mr. W. Chaster called my attention to it. I have also overlooked the query 54934, Vol. XL., and the reply of "Cyrax." I take this opportunity of apologising to these gentlemen, as a serious illness at that time prevented me from exhausting the pages of the "E. M." so completely as it is my usual custom to do.

Now, as to the 1in. compression, I will endeavour to render the mystery so palpably clear that even Mr. Chaster may admit the *possibility* of the established fact that such compression is not only necessary, but easily performed. The discs, or strips, forming the armature according to my design, were stamped out of best charcoal sheet iron, and everyone who has had any experience with such stamped pieces of metal, knows that although the thickness of each disc may be $\frac{1}{20}$in., it requires considerable pressure to force 20 discs within the space of one inch, by reason of the distortion of the iron during the operation of stamping.

I find, in practice, that 110 discs $\frac{1}{20}$in. in thickness, occupy 6½in. to 7in. of spindle before screwing up. Perhaps the makers of some of these small laminated armatures may verify my assertion. I still maintain that the cross form of armature, when wound with four coils, is highly efficient as a motor, and wound with two coils is a good dynamo, certainly far more efficient than the solid H form, and with either method of winding holds sufficient wire for the purpose. I believe I am the originator of the lamination of these small armatures; and, according to Mr. Bottone's recent test, it appears to have been a step in the right direction.

I am compelled to deal with that portion of Mr. Chaster's letter which reflects upon me personally in a somewhat sterner manner. He, taking advantage of the coincidence that Mr. Harcourt apparently resides in the same district as myself, insinuates that we are in collusion, and hints at the existence of a "clique." I can assure Mr. Chaster that, to the best of my knowledge, I have never seen nor spoken to Mr. Harcourt; and, further, that any matter contributed by me to these pages during the past sixteen years has been of a *purely disinterested* character, and not *directly or indirectly as a means of gain to myself*. My purpose has been simply to contribute my humble quota to the mutual good fellowship that has so long existed between the readers of "Ours," and has justly earned for the English Mechanic that familiar appellative.

My professional reputation as a practical engineer of considerable experience does not require the support of a "clique," and I am thankful to say is established upon a basis too firm to be shaken by Mr. Chaster's innuendoes.

**Fredk. Walker.**

36, Spondon-road, Tottenham, April 6.

## THE MUSICAL SCALE.—TO "A. S. L."

[24096.]—You have misunderstood the tables of intervals given by me on p. 11. They are the complete set of notes required for just intonation in the major, and all the minor scales on the keynote C. When these intervals are remeasured from other keynotes, three new sounds are required in the scales for every flat or sharp remove, and for this reason about forty-two sounds in the octave are required by the musical ear for all the keys in modern use. Our instruments with but twelve sounds in the octave cannot, therefore, give the notes with "the ratios as determined by the musical ear," and here equal temperament is called in that all keys may be played in with equal facility and incorrectness, and this is a method of pretending to play in all keys, and, in reality, playing in none, simply to save trouble. What would be said of a sculptor who made the fingers of his models all the same length simply to save trouble?

Before some of the great composers advocated equal temperament, these imperfect instruments (piano, harmonium, organ, &c.) were only used in a very limited number of keys, being tuned on an unequal temperament principle where some five or six keys were much nearer perfection, and the rest left with errors so intolerable that they were seldom used. I suppose no one would go so far as to say that these masters of song would have advocated equal temperament, had they had the choice of just intonation on these instruments; but they felt their genius bound down and restricted when writing with such a limited number of keys at command. It might be that, having a faith in the achievements of mechanical science in the future, they were content to put up with the errors of equal temperament, knowing that some day their music would be interpreted by just intonation. Is not the time at hand when just intonation can compete with equal temperament for facility of execution and completely outrival it in every other musical requirement?

This equal temperament consists in taking for the note used as C sh. and D fl., a measure which is such a fraction of C that its square will give the measure of D, its cube the measure of D sh. or E fl., its fourth power the measure of E, and so on until its twelfth power gives the measure of upper C, which must be exactly one-half of the lower C, and this octave is the only interval musically correct. It naturally follows that these notes are in most complicated relations to each other, and so do not fulfil the first requirement of true music—viz., simplicity of ratio between the notes of the scale; but this is secured if the scale be evolved by the process set forth on p. 10, No. 1,041.

Another way of putting it is this: Thirteen notes from C to C, or from any other keynote to its octave, are made to stand at the following proportions:—1, $\sqrt[12]{\frac{1}{2}}$, $(\sqrt[12]{\frac{1}{2}})^2$, $(\sqrt[12]{\frac{1}{2}})^3$, $(\sqrt[12]{\frac{1}{2}})^4$, $(\sqrt[12]{\frac{1}{2}})^5$, $(\sqrt[12]{\frac{1}{2}})^6$, $(\sqrt[12]{\frac{1}{2}})^7$, $(\sqrt[12]{\frac{1}{2}})^8$, $(\sqrt[12]{\frac{1}{2}})^9$, $(\sqrt[12]{\frac{1}{2}})^{10}$, $(\sqrt[12]{\frac{1}{2}})^{11}$, $(\sqrt[12]{\frac{1}{2}})^{12}$, or ½, and it would appear that your intermediate curve ordinates are identical with these; but it would be interesting to inquire why the measure for E flat shows a difference from $(\sqrt[12]{\frac{1}{2}})^3$. You will note that the measure for F sharp, the tritone both in the curve ordinates and equal temperament is an attempt at the square root of ½ or $(\sqrt[12]{\frac{1}{2}})^6$, but the musical mission of F sharp is not thus to lie intermediately between the extremes of the scale; but in its nearest relationship to the key of C to act as the leading note to the scale on G, and so must be $\frac{8}{15} \times \frac{4}{3} = \frac{32}{45}$ or ·7 $\pi$.

The following table contrasts the true notes in the key of C, with the equal-temperament notes, and your curve ordinates. The flats correctly have a place in the minor scales; but the sharps do not belong to the key of C, being signs of modulation into other keys, so in every instance I give these as the measures of the leading notes to the natural tones above:—

| | True measures. | Equal temperamnt. | Curve ordinates. |
|---|---|---|---|
| C .......... | ·5 | ·5000000 | ·5000 |
| B .......... | $\cdot 53\dot{3}$ | ·5297316 | ·5297 |
| B fl. acute .. | ·555 | ·5612310 | ·5613 |
| B fl. grave.. | ·5625 | | |
| A sh. ...... | $\cdot 56\overline{88}$ | | |
| A .......... | .6 | ·5946036 | ·5946 |
| A fl. ...... | ·625 | ·6299605 | ·6299 |
| G sh. ...... | ·64 | | |
| G .......... | ·666 | ·6674198 | ·6674 |
| F sh. ...... | $\cdot 7\overline{11}$ | ·7071068 | ·7071 |
| F .......... | ·75 | ·7491535 | ·7491 |
| E .......... | ·8 | ·7937005 | ·7937 |
| E fl......... | $\cdot 8\overline{33}$ | ·8408964 | ·8404 |
| D sh. ...... | $\cdot 85\overline{33}$ | | |
| D acute .... | ·888 | ·8908986 | ·8909 |
| D grave .... | ·9 | | |
| D fl......... | ·9375 | ·9438742 | ·9438 |
| C sh. ...... | ·9481 | | |
| C .......... | 1· | 1·0000000 | 1·0000 |

I notice that "W. H.," page 478, No. 1036, sets A sharp above B flat, and so with all the other sharps and flats; but I hold his method of arriving at the measures by a succession of perfect fifths (or by inversion fourths) to be inaccurate, as no number of perfect fifths can exactly equal any number of octaves. Compare his thirds and sixths with the equal temperament, as given by himself, and you will see the errors are increased rather than diminished; or, better still, tune to his measures, and hear how they sound.

I am so interested in this subject that I have advertised my address this week, and shall be happy to correspond with yourself or any other gentleman similarly interested, as far as my limited time will allow. Our Editor is very kind; but he has many other subjects that equally claim the space he has at disposal.

**S. E. Hunt.**

[24097.]—If this correspondent will compare the curve-ordinates he gives on page 58 with the corresponding monochord-lengths for the scale of *equal temperament* given by Mr. Elphick on page 434, and myself on page 478—both in previous volume,—he will find that they are almost identical, the differences being so slight that they may be set down to error in calculation, or more probably to the inevitable incompleteness of statements in decimals.

March 28. **W. Hardie.**

## CUTTING SCREW-THREADS.

[24098.]—Dr. Edmunds will see from my last note (acknowledged only in No. 1,045) that I agree with himself as to the importance of the deformation, or, as he objects to the term, the abnormal form, of his proposed thread. I still think that the position Mr. Wenham conceives himself to have taken up is the same as my own (23973), though it was originally, and is still really, too general and erroneous in being so.

I mentioned the chaser only as an illustration. The main cause of uneven working with a chaser is not quite as Dr. E. (24038) supposes, but is due to the large contact surface or cutting edge. It would, of course, be better to fit the wheel to the bit that cut the chaser, the which would probably (Mr. W. notwithstanding) have been finished by a rotating lap. The chaser acts as an illustration, on account of its being axial on its cutting edge, not normal, as a V-point tool.

The variation from the normal to the axial in base width, though I had thought of it, was not the matter I wished to point out; quantitated, it is very slight. And I also agree that the stress on thread on a mandrel nose is normal. My long phrase simply meant "axial section."

The point with myself is that, whereas the thread is spoken of as 50°, neither section—axial or normal—is truly so; but the section of the groove or nut-thread has a true 50° normal section. If nut and nose are to be alike, it is necessary to have the 50° or other angle *axial*.

If the *nose* is preferred with the true angle normal, the cutter may easily be shaped as mentioned in my last, or a 50° *grooved* lap to operate *on* the nose thread, and not in the space, may be used—perhaps the simpler-made tool. But, as also before stated, the abnormal original thread has its advantages of being more upright and thicker-topped, the nuts being many, and the nose one to wear.

Dr. E. will, perhaps, see that it is not by any means necessary that "the normal cross section of a spiral thread will, in all cases, be a portion of a spiral surface;" it is easily in nut or screw made a straight line. The *normal* is, of course, spiral when the *axial* is straight, as should be the case for both.

In saying that "the stress borne by a screw-thread is not axial but normal, inasmuch as it is resolved into its component parts," it appears to myself that a reversal of the reason has been made. The theoretical stress on a screw-thread is, no doubt, normal; but the reason is that the longitudinal and transverse stresses compounded have a resultant coinciding with the normal. Practically, however, the stress is reduced by friction to a longitudinal one; this I have often seen in bolts broken or stripped in situ, no trace of torsional action being observable, or shifting of the nut or bolt taking place before rupture. Perhaps the grain of the material is largely the cause.

**Vulcan.**

## ALARUM CLOCKS ADAPTED TO THE USE OF EXPERIMENTERS AND OTHERS.

[24099.]—I am desirous of calling the attention of manufacturers of alarum clocks and watches to a great *desideratum*. Ordinary alarum clocks are made with a view to sounding a lengthy and startling noise many hours after being set, and with a rough approximation to correctness—that is to say, such a clock would not be judged defective though it went off a few minutes before or after the time intended. But an immense boon to most of us would be a form of the instrument which, though only capable of being set for moderate intervals of time—say, less than half an hour—could be depended upon to go off within a few seconds of the intended time. A loud, long-continued sound would be quite unnecessary in such an instrument; one stroke upon a small bell would be sufficient, as the object is to call attention, not to awaken the sleeper.

It would be an endless task to attempt to point out the various uses of such a time-warner or *monitor*. The experimentalist, the photograper, the astronomer, each so often requires that his attention shall be directed to an operation, say, in 3, 5, 7 or other number of minutes. Afraid of overlooking this, he, in the absence of such a *monitor*, has simply to waste these minutes, for he feels the danger of settling to any engrossing work; but had he the "monitor" by his side, or in his pocket, no minute need be unemployed. And even to the non-scientific individual the monitor would be a boon. How often, for instance, we have everything ready, it may be, to start from home to fulfil an engagement; but find we have ten minutes or so to wait. These we probably squander by glancing over a newspaper, or, it may happen, we light upon a subject so interesting that the minutes fly past unheeded, and we start up to find we are too late. Descending to a still commoner illustration, how tiresome to watch the clock, or even the sand-glass, when boiling an egg! I fancy it is sufficient to propound the question of the usefulness of such a companion to have acquiescence all round.

The "monitor" might be brought out in two or three useful forms:—

1st. A cheap one to stand on a table, or hang on a wall, of a size to provide for good rough workmanship.

2nd. A portable instrument like a watch.

3rd. Watch and monitor combined. **Abacus.**

## REPLIES TO QUERIES.

*** *In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[54825.]—**Salt, &c.**—"Backwoodsman," in reply to this question, seems to dispute "Dens's" assertion as to the non-reproduction of the cereals from their own seed in their wild and uncultivated state. I have before me (*Sunday at Home* for 1878, p. 520) a very interesting and instructive paper on this subject by Alexander Harvey, M.D., Professor of Materia Medica in the University of Aberdeen, which deserves "Backwoodsman's" perusal. It is compiled under the following headings:—1. What are the Cereals? 2. The Cereals are all Annuals. 3. The Cereals, Artificial Plants only Produced under Cultivation. 4. The Original or Uncultivated Form of the Corn-plants Unknown. 5. The Cereals do not Revert to any Natural or Uncultivated Type. 6. The Cereals do not Reproduce Themselves and Multiply by Natural Agencies. 7. Cereals Speedily die out if not Under Culture. 8. The Cereals being Artificial Plants, require Artificial Soil or "Agricultural" Help. 9. The Cultivation of Cereals not a Natural Discovery, but Taught to Man and Continued by Tradition. 10. The Cereals given by God to Man for Food, and their Cultivation Appointed. It is, I think, clearly proved from this, and supported by authorities, such as Prof. Balfour, Mr. A. Stephen Wilson, Prof. Lindley, Prof. Bentley, and others, that the cereals are dependent, next to the increase from a higher power, upon the will and efforts of man, and man, too, in his civilised and enlightened state; and this, too, will probably go far to meet the question now going forward in the pages of "ours" upon "The State of Man." Prof. Harvey says: "Nature alone sufficeth for all the brute orders around us, but not for man. This is, physiologically, demonstrable; and it is as certain as anything can be (because it could not have been otherwise), that the primitive ancestors of our race came into the world civilised, or became, or were made civilised from the first. The savage races now existing are, as Archbishop Whately has shown, the remnants of races once civilised, but long since degraded, and now incapable of themselves of taking the first step towards regaining the lost civilisation."—Marienberg.

[55219.]—**Edges of old Violin Splintering.**—Give the edges a coat of thin glue, rubbing it well into the interstices. Sponge off the superfluous glue when dry. I treated an old Cremona in this way very successfully.—Thos. Lisle.

[55723.]—**Gramme Dynamo.**—To Mr. S. Bottone.—Wind the ring with about 1½lb. No. 18 double cotton covered, and the fields with about 6lb. of No. 16. A wooden hub is keyed to shaft, this is slightly coned down, and forced into wound ring, and cemented with good electrical cement. Probable lighting power at 1,400 revolutions, about 6 ten-candle lamps.—S. Bottone.

[55843.]—**Photo-Micrography.**—Now you are able to get clean plates, the rest is comparatively easy; in all probability you do as many other amateurs, and develop too quickly. Begin by giving 8 or 10 seconds exposure with your ¼in. objective, proceed to develop; notice whether the picture appears nearly directly and "greys" all over, or whether it takes more than one minute to appear. In the former case, diminish the exposure to 5 seconds; in the latter increase it to 20. Now, in developing, leave the plate in the solution until the image is visible at the back of the plate; rock continuously. By such treatment the plates should require no redevelopment.—S. Bottone.

[55870.]—**Optics with the Lantern.**—To Mr. L. Wright.—I am much obliged to you for your offer. I am sorry to say I am far from London, but expect to be there in a week or two. May I then call on you in person, if the Editor will allow me to have your address by calling at the office of English Mechanic? I am anxious to see "Excelsior's" promised letter.—S.

[55932.]—**Plating Dynamo.**—If you wish to overcome your difficulty you must go to work methodically: 1, ascertain the resistance of your plating bath in ordinary working condition; 2, test the exact resistance of dynamo; 3, measure its E.M.F. at the speed most convenient for you to run it at; 4, divide the E.M.F. by the entire resistance. This will give you the actual current in ampères. If the current is not sufficient, remembering that electromotive force of the dynamo increases with the number of turns of the coils, while the current diminishes with the resistance, and bearing also in mind that the most economical work is got out of the machine when the external resistance is equal to that of the entire dynamo, it will be easy for you (with a table of conductivities of different sized wires before you) to decide what alteration you must make in the winding of your dynamo to give the required number of ampères.—S. Bottone.

[55980.]—**Electric Bells.**—This question really refers to the use of the galvanometer. I am not quite sure whether the book issued by Gent, of Leicester, describes the method of testing the work by the galvanometer; but "Novice" would do well to get it, and then look up his back Nos. Culley's "Handbook of Practical Telegraphy" gives full particulars of the methods employed for locating the position of faults. I should think it most likely that those who sell this "Bellfitter's Galvanometer" supply "directions for use" with it.—Nun. Dor.

[55984.]—**Polishing Wood in Lathe.**—This query is not definite. Polishing wood in lathe means putting a very smooth surface on it; but I suspect the querist means varnishing wood in lathe. Brush polish is the article required, and apply it with a piece of cloth or with a brush, if the parts cannot otherwise be reached. I believe some people make it by mixing two parts of French polish with three parts of brown hard varnish.—Essar.

[55986.]—**Battery for Sewing-Machine Motor.**—Use a solution as follows:—Bichromate, 3oz.; sulphuric acid, 9oz.; water one pint. Dissolve the salt in the water, and add the acid very slowly. The battery will, of course, fail after a short time; but to make it do constant work you can arrange the cells so that a circulation of the liquid is kept up. Whether the battery described would work the motor named is quite "up in the clouds," for you see, the motor may be of any size for all you tell us. The best way will be to try.—Nun. Dor.

[55989.]—**Lathes.**—If "Belgian" wants to fit up an overhead motion, he ought to get Vol. XXII., which contains a series of articles by "D. H. G." on the subject. There are several overheads described in back volumes. Perhaps one in No. 586 will suit him.—T. M.

[55999.]—**Elliptical Chuck.**—See illustrated article by Mr. Evans, in No. 850, on oval chuck, and several others in back volumes.—T. M.

[56015.]—**Steam Hammer Valve.**—I am afraid that there are not enough readers anxious to make steam hammers to warrant me in asking the Editor to append sketches of the valve-motion, which anyone can obtain by procuring the patent specifications. In the automatic hammer the motion to work the valves has been obtained by means of inclined grooves, diametrically opposite each other, which work a brass yoke, whose line of vibration is through central axis of bar. A supplementary valve throttles the exhaust below the piston, and thus provides a cushion of steam, which stops the hammer, if necessary, in the "middle of the stroke." Indeed, it is possible to put an egg into a wineglass, and just break the shell without injuring the glass; but it needs practice.—Essar.

[56025.]—**Trueing Grindstone.**—Let me premise a few words. "E. M." says: "The action is more important than the name"—i.e., than the name of the material to be used as the point of the turning tool. This is far from being so—for, 1st, he would find the cost of the diamond (gem) prohibitive; and, 2nd, he would "rate" me roundly if I mixed up the two things, especially when he found that the expense was so great in the one case as to render the idea "practically useless"; whereas if he had attended to the proper name of the point for the tool, he would find it effective. Again, let me say that I have seen a diamond (gem) used for turning emery wheels to size, truth, and shape. In this case the diamond was set in the end of a soft steel bar, and held by the soft steel bar being pressed on to it (I forget the name for this operation), in the same way that the gold in setting a diamond ring is pressed on to the diamond to hold it in. Again, speaking from my own observation, I have seen the extraordinary action of the emery cut off by the diamond (gem) tool—viz., it actually, by the friction of the emery flying off from the velocity of rotation, cut the steel tool away! Again, the diamond (gem) tool for "trueing up" the emery wheels was advertised and sold by the emery-wheel manufacturers. Now I believe that as carbonado *will*, from my *own* knowledge—

1. Cut hardened steel.
2. Cut millstone grit.
3. Cut out the teeth of a file from end to end.
4. When powdered act almost as well as the powder of the gem diamond or the powder of bort (the impure gem),

it will, without a doubt, turn a round or hollow face on an emery wheel. The tool would be used dry, unless the operation made the emery wheel soft by heat, when water could be used without detriment to the tool. In other words, water might be necessary for the thing operated on, but not for the tool. "E. M." asks as to speed. Surely this is not very important—I mean the speed of the emery wheel. Again, it depends on the size, for "E. M." does not ask "surface speed," and if he had done so I should have given the same answer, but with this caution, "Recollect, you have a brittle tool." Where can carbonado be obtained? says "E. M."—Answer: Advertise in the "E. M." "E. M." says "selection." This I have adverted to in a former letter. Get, if you can, the small natural pieces, and not pieces of a larger piece; you want the natural crust. "E. M." asks price. It used to be about 2s. 6d. to 3s., the size of a pea—a small one. Present price I cannot say; but as it is much used for rock drills instead of the diamond (gem), I daresay the price has gone up. I will now give my plan of 1869 for holding the carbonado in the tool, which I used for turning hardened steel—hardened as hard as fire and water could make it. In 1869 I said, in a letter to "Ours": "Take a piece of steel or iron, size and shape of an ordinary slide-rest tool. At the end (or at the side, if for cutting inside a cylinder), bore a hole very little larger than the piece of carbonado to be used (I made use of a small piece of irregular shape). Then heat the end of the steel or iron. Having put in soldering liquid, add solder till it is full, and nice and liquid, then insert the carbonado, taking care to leave a point uppermost, and protruding very slightly beyond the steel or iron. Cool whilst holding the carbonado." In "Ours" of January, 1869, "Use as an ordinary tool, but with care, as the tool is brittle." I used the tool in 1869 to true up a hard, close-grained Welsh grindstone. An ordinary grindstone, as I stated in 1869, it makes short work of. I have intended to fully answer "E. M." If I have not done so, if he will write again, I will endeavour to answer more fully if I can; but I think I have given about all the information I possess.—Z. Y. X.

[56025.]—**Trueing Grindstone.—Patent Law.**—It is evident "Z. Y. X." does not understand why I wrote the reply on p. 66, for he thinks it was specially written for his benefit. Nothing of the kind; it was written for the information of all who cared to read it. If it had been merely a reply to his expressed opinion on p. 40—"there has latterly been a great tendency in 'Ours' to get at trade secrets and the mode of getting round a patent," and his explanation of the prohibition clause in the Letters Patent—it would have characterised the former as nonsense and the latter as incorrect. For the information of those who do me the honour to read and understand what I write, I quote the actual words of the prohibition clause:—"We," &c., "strictly command all our subjects," &c., "that they do not at any time during the continuance of the said term of 14 years, either directly or indirectly *make use of* or put in practice the said invention, or any part of the same, nor in anywise imitate the same, nor make or cause to be made any addition thereto or subtraction therefrom, whereby to pretend themselves the inventors thereof, without the consent, license, or agreement of the said patentee." It will be seen that this is not exactly "Z. Y. X.'s" "making, using, vending, or exercising."—Nun. Dor.

[56041.]—**Gun Metal.**—Thanks to "Nun. Dor."; but, with great deference to him, I still doubt iron being, or forming any part, of true gun metal. I am aware to-day, if not before, that many metals can be mixed together, though the melting power of each is vastly different. I knew (may I add, of course) that when copper and zinc had to be mixed, the copper was melted first, and then the zinc added; but then, as "Nun. Dor." says, special precautions must be taken not to lose zinc. Now, iron does form part of the component parts of "Delta metal," and, as "Nun. Dor." says, of many other alloys. Now, my letter was confined to gun metal, and not to alloys generally. I must repeat as to back volumes, I cannot refer to them, though I have been a subscriber since before 1869, and pay for an extra copy for a country coffee house. My copies go to the hospital, near my house, for the amusement of the patients.—Z. Y. X.

[56087.]—**Dynamo.**—1st. A shunt-wound dynamo, with fine wire, would give a current of high E.M.F. with a small current. This would probably be the cause of the failure of "Naval's" dynamo in producing large sparks from his coil, also the high tension of the current would be liable to produce leakage. 2nd. The position of the brushes should be such that when the iron cheeks of the armature are opposite the faces of the pole pieces of the field-magnets, then the brushes should be resting on the slit of the commutator.—S. Bottone.

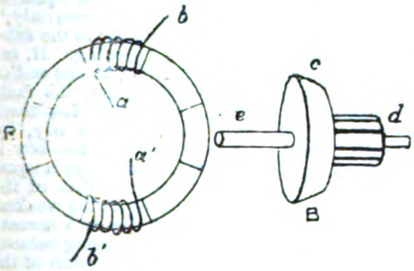
[56102.]—**To Mr. Lancaster, or Mr. Bottone.**—Use about 50 sheets of tinfoil, 4in. by 5in., separated by sheets of paraffined paper. Connect 1, 3, 5, 7, &c., all together on one side, and 2, 4, 6, 8, &c., on the other. Join one set to the pillar supporting the vibrating hammer, and the other to the pillar carrying the platinum screw.—S. Bottone.

[56112.]—**Testing for Arsenic in Wall Paper.**—In reading Mr. J. Kean's reply to the above query, I observed that he overlooked the fact that the presence of antimony would give almost, I may say exactly, the same results; that is to one who had neither made the experiment or seen it performed. I think Mr. Kean should have pointed out this fact; and also how to distinguish one from the other. Of course, a practical man would know that arseniuretted hydrogen burns with a bluish flame, whilst antimoniuretted hydrogen burns with a bluish-green flame; also that the mirror in the tube would form, in the case of arsenic, at a greater distance from the heated part of the tube (owing to it being more volatile than antimony) than the antimony, the antimony mirror being formed close to the frame, whilst that of the arsenic is some distance off; but I don't suppose that any chemist would care to give a certificate of analysis showing the presence of arsenic on the strength of the black stain as described by Mr. Kean, even when coupled with the preceding observations; but would, at least, substantiate his results by at least one confirmatory test. The simplest and readiest way to distinguish arsenic from antimony is to add a few drops of sodic hypochlorite to the black film on the porcelain, when, if the film is arsenic, it will be rapidly dissolved. If antimony, it will remain undissolved.—R. FORREST.

[56112.] — **Testing for Arsenic in Wall Paper.**—Let "J. K." take a piece of the suspected paper, about 2in. square, and soak it in as much strong liquid ammonia as will cover it, then, after removing the paper, add a crystal of nitrate of silver, and if it turns a distinct canary colour As is present. I think "J. K." will find the above much simpler than the test given by J. Keen, owing to the difficulty of obtaining zinc free from arsenic. —STUD.INST.C.E.

[56114.] — **Electro-plating Dynamo.** — Your question is rather ambiguous. Do you want to know what E.M.F. and what number of amps you ought to have for plating? or do you want to know what E.M.F. your dynamo as wound will give? In the latter case much will depend on the speed at which you drive; but such a machine would give from 30 to 60 volts., and a current (on short circuit) of from 60 to 120 amps.—S. BOTTONE.

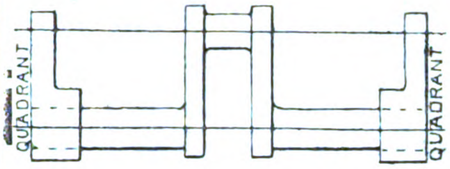
[56117.]—**Pacinotti Ring.**—To MR. BOTTONE. —Suppose your ring is to be wound in eight sections. Start all your windings on the same side of the ring, as shown at R. Let your endings all look the same way.



When all the sections are wound, a shaft *e* (see B), to which is keyed a hub *c*, and an eight-leaved commutator *d*, is driven in the ring and cemented to it. The ends of the wires *b b'*, &c., are connected to the strips on the commutator, while each beginning wire *a a'*, is connected to the wire diametrically opposite to it, and not to the commutator at all.—S. BOTTONE.

[56123.]—**Wire for Dynamo.**—To MR. BOTTONE.—About 4lb. on each leg would do very well. E.M.F. about 40 volts; current about 16 ampères. You might light six tens in parallel.—S. BOTTONE.

[56127.] — **Turning Small Cranks and Setting Lathe Heads.**—In crank forgings, that part intended for the pin and crank is usually forged as a solid web. The forging is next marked off as follows:—Scribe a centre line along one side and across the ends of the shaft, and a second one across the web for the centre line of pin. Mark off the size of pin and width between "jaws" of crank upon the web; then cut away the part not required out of the web. Perhaps the best way to accomplish this in such small cranks would be to drill a hole through the "web" near the pin, and then saw the piece out, taking care, however, to keep well clear of the marks, so as to allow for machining. Next, mount the shaft in the lathe, and turn down to about "three-sixteenths" above finished size; after this fit a "quadrant" (as we call them here) on each end of shaft, and fix them firmly by means of keys or set bolts. Now, mark off and carefully drill a "centre" in each "quadrant," measuring from "centre" of shaft—the distance between the "centres" in the shaft and those in the quadrants being equal to the "throw" of crank; and take care that the two centre lines are truly parallel with each other. The whole is then mounted in its new "centres" in the "quadrants" and the pin turned. (I presume it is needless to occupy space to tell you what kind of tools to use in turning the pin?) After turning pin, the "quadrants" are taken off, and the shaft mounted in its own "centres" and finished. But before doing this it will be necessary to fix a "stay" between the "jaws" to prevent the shaft springing out of truth when the back centre is screwed up. I append small sketch, which will doubtless render my remarks somewhat clearer.



I think the easiest way for you to line up your lathe heads parallel with each other would be this:—Start with fixed head; mount a piece of work in chuck, and adjust your lathe head until it turns parallel; then put liners on tenons to suit. For the back head.—Mount a plain cylinder between centres, and adjust headstock so that your lathe will turn it parallel, and notice that it turns parallel both when back centre is well screwed out and also when it is "home" before fixing liners on tenons permanently. If the above information is insufficient, I will supplement it through the post should you care to advertise your address.—AN ENGLISH MECHANIC, Newcastle-on-Tyne, March 29.

[56132.]—**Cutting Iron Pipes.**—I must thank Jno. M. Adams for pointing out an error in my reply to this query. In transcribing the figures I put a 2 for a 6, as one may see by working out the equation. The correct answer should be 24·269ft. Mr. Adams's an wer is in error, as well as his method, and I may return the compliment of being "a' vrang thegither," as "one good turn deserves another," or in Scotch language, of which Mr. Adams is so fond, "you scratch my back and I'll scratch yours."—GEO. F. WALTON.

[56132.]—**Cutting Pipes.**—On page 67 Geo. A. Walton gives an answer to this query which seems founded on a mistake. He assumes that the length of B E (in "M. B. M.'s" diagram, see page 43) is equal to that of B F; but a glance at the figure shows that B E must be shorter, the angle at E being a right angle. But even if the length of B E (which is what "M. B. M." says he wants) were correctly stated, it would not by itself much help in cutting the pipes. In fact, if the diagram represents the way in which "M. B. M." proposes to join the pipes, he is simply trying to accomplish an impossibility. If the pipes are to be cylindrical the two portions could not be joined at the section indicated on the diagram by the line B C. A B C D being "square," the jointing top edge of that piece of pipe is, of course, a circle. But the lower end of the upper pipe which joins on to this being cut slantingly, its section must be an ellipse or oval whose length is B C, and its breadth equal to E F, which is shorter than B C. Now an oval cannot, of course, be fitted on to a circle so as to join all round. If two cylinders are to be joined end to end at an angle, neither of the joining ends must be cut square across, but both must have an equal slope. Having had occasion to cut pasteboard tubes for the purpose of joining the ends at an angle, I have found the following method answer perfectly:—Let A F G D (Fig. 1) represent the tube uncut, A D being equal to the diameter of the tube, and let the angle F C D show the amount of bend we wish to give it at the point C. Measure off F B equal to F C. Draw B C, which will bisect the angle F C D; also B E parallel to F C and equal to C G; then join E F. A B E F C D now represents the longitudinal centre section of our bent tube. Upon and beneath the base A D draw a semicircle and divide its arc into a convenient number of equal parts (the more numerous the better). From the dividing points draw lines 1, 2, 3, &c., parallel to A B, crossing A D, and ending in B C. Now wrap a piece of stout paper tightly round the tube and prick a pin-hole through the two overlapping edges. Then lay this sheet flat, and draw a straight line upon it from one prick-hole to the other. This line is the length of the circumference of the tube (A A, Fig. 2). Divide it into equal parts, twice as many as the semicircle in Fig. 1 was divided into, and upon the division points erect perpendiculars. Of these, make the middle one, D C, equal to D C in Fig. 1; the two next it (one on each side) equal to line No. 1; the next pair outside these equal to line No. 2, and so on to the extreme end perpendiculars, which make equal to A B. Now draw a curve joining the tops of all these perpendiculars, and carefully cut the paper through this curve. If the paper be now wrapped round the tube so that the pinholes again coincide, its curved edge will define the line and plane through which the tube must be cut, which line can be easily marked on the tube by tracing with pencil or otherwise along the curved edge of the paper. When the tube is cut, and one portion turned half-way round, the cut ends will be found to fit exactly when placed together, and the two parts will make the required angle with each other. The measurements of the perpendiculars need not be taken from the line A D (Fig. 1). The same curve will be produced if they are measured from any other line which is parallel to A D. I trust "M. B. M." will be able to adapt the above process to the cutting of his wrought-iron pipes. In the particular case which he states (or, I believe, intends to give) in his diagram, the length of E B is very nearly 24·27ft.; A B should be 9·27ft. (not 10), and the whole length of pipe before cutting need not be more than 34·27ft., not including flanges or overlaps at joinings (see Fig. 1). —W. HARDIE, Joppa.

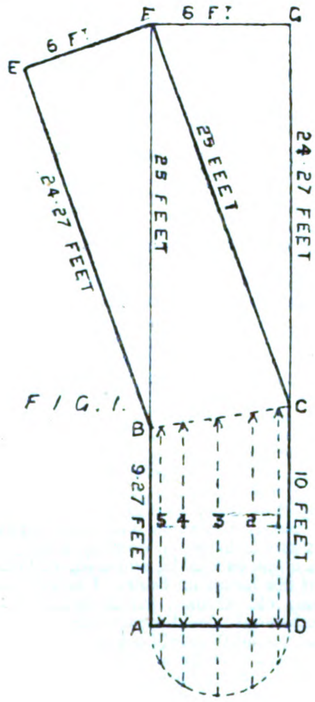

FIG. 2.

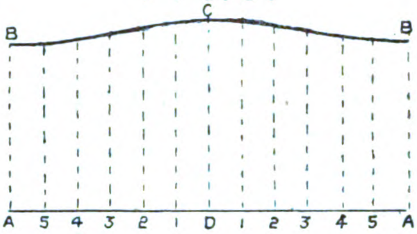

[56139.] — **Boot-Cleaning Machine.** — The following, from a French paper, may give the querist an idea; but I believe he can see boot-cleaning machines at work in some of our large hotels:—The principle of an apparatus for polishing boots and shoes dates back to 1838, the epoch at which a machine of this kind was put into use at the Polytechnic School of Paris. Since then it seems that
